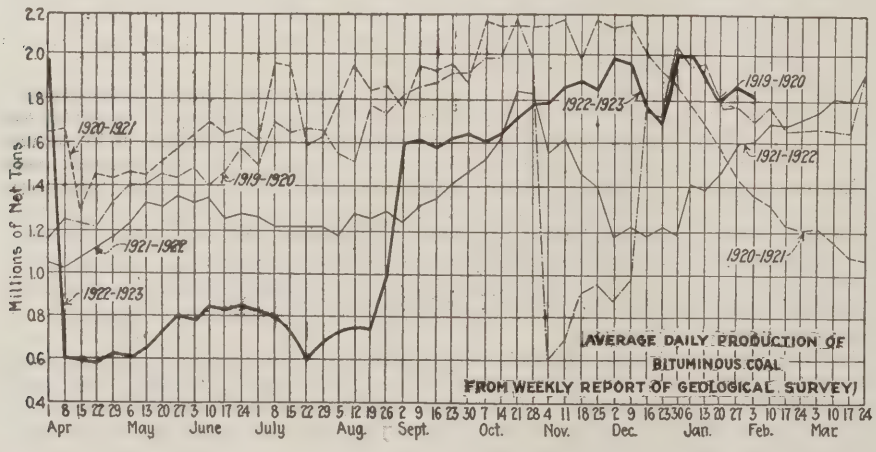
The renewal of the wage agreements in the Pittsburgh and central Pennsylvania districts was to be expected following the signing of the agreement between the operators from Illinois, Indiana and eastern Ohio, and had no effect on the situation. With spring nearly here and assurances that there will be no serious labor disturbances, consumers have no apprehension. They are not anxious to buy more coal than they really need but are willing to pick up bargains.

Consumers Not Anxious to Make Contracts.

Nor are consumers ready to make contracts for the year beginning April 1. Many tentative figures have been heard at which operators are willing to sign up for a year's supply, but few contracts have been closed.

Car supply continues poor in most sections of the country. Because of continued embargoes via the Hudson River gateway the all-rail route to New England is effectually closed. Pennsylvania operators are under heavy pressure to place within much restricted territory what they can produce even under present conditions of car supply. Practically all bituminous coal for commercial purposes is excluded by certain of the railroads from the all-rail route. As a result the restrictions on shipments into New England were reflected in the receipts at the New York terminals.

Lack of cars and cold snaps in various sections of the country were the factors that kept prices from a lower level. Mines in most instances did not work more than half time and weather conditions were not such as to result in heavy consumption of coal.



The trade was interested in bids opened by the United States Shipping Board at New York on Jan. 29 for furnishing about 8,000 gross tons of coal alongside vessels in that harbor. The prices submitted ranged $7.33 @$9.10 for three months delivery and $7.20@$8.74 for six months delivery, the coal to be the equal of Pools 1, 9 and 71. Later in the week the bids were rejected on the ground that the prices were too high. It has not been announced whether the bids would be re-advertised.

Anthracite production continues at around 2,000,000 net tons per week. Already dealers located from three to four weeks from the point of loading are said to be cancelling orders where placed with the smaller producers quoting high prices. Producers are watching the progress of the coal-grading bill introduced in the Pennsylvania State Senate, making it unlawful to misrepresent the grade of coal sold or offered or advertised for sale. The bill covers anthracite, bituminous, semi-bituminous and all other grades of coal.

Senator Walsh of Massachusetts, who has advocated the cutting off of shipments of anthracite to Canada, has sent to the U. S. Senate a communication complaining of bad preparation and also has introduced a bill establishing standards for anthracite shipped in interstate commerce.

Production of coke is limited by the car supply. A shortage of labor now and then at various works makes it possible to give the other workers nearly full employment. Demand for coke for heating purposes continues strong.

"The rate of production of soft coal has been station-

Estimates of Production

(Net Tons)

	1922	1923

Calendar year	455,000	1,307,000

(*a*) Subject to revision. (*b*) Revised from last report.

ary at about 11,000,000 net tons a week during the past four weeks," says the Geological Survey. "First estimates for the week ended Jan. 27 place the total, including mine fuel, coal coked at the mines, and local sales in addition to shipments, at 11,160,000 net tons, which is a small increase as compared with the revised estimate, 10,925,000 tons, for the week preceding.

"Preliminary reports of cars loaded during the present week (Jan. 29-Feb. 3) show 42,659 cars on Monday and a decline to 29,218 cars on Thursday. Thus the indicated total output for the present week is between 1 and 2 per cent less than for the week preceding and will be about 10,900,000 to 11,000,000 tons."

Midwest Is Uneasy

Short car supply together with a cold snap which swept down out of the Northwest at the end of last week were the two factors which staved off the long-imminent market collapse. Most Indiana and Illinois fields worked something less than half the time, which was quite enough to balance the demand. The general expectation was that the cold would continue less than a week, so there was nothing resembling a rush to market for coal. Instead, dealers everywhere kept up their clamor for further price reductions.

Indiana producers shaded their lists 25c. or 50c. at the middle of the week, dropping Fourth Vein lump back to $4.25@$4.50 and Sixth Vein to $4.50@$4.75. Central Illinois lump could hardly maintain a level of $3.75. Some sold down to $3.50. In each case there were more cars than were needed, even at 50 to 60 per cent supply. Southern Illinois association operators did not give up their $5.50 price for lump and egg, however.

A feature of the domestic market in Chicago was the dropping of the retail price of Pocahontas mine-run from $11.50 to $10 by a dealer big enough to upset the market. At once there was a general stirring about followed by a tendency on the part of the mine price to drop from $4.75@$5 down to at least as low as $4.50. A good deal of this Eastern coal is reaching Chicago just now.

Steam demand continued light, but the small volume of steam coals available kept the price from sinking much. In the case of one or two coals it even rose a faint shade. Fourth Vein screenings attained $2.50 as a top. Nobody anticipated any general rise of small sizes, but screenings are expected to hold their own for a while. No stocking is noticeable on the part of any big consumer. Buying is on a day-to-day basis.

This day-to-day tendency is most obvious in St. Louis, where few dealers stock heavily, since coal fields are so close at hand. That market has been taking light tonnages for

Coal Age Index 312, Week of Feb. 5, 1923. Average spot price for same period, $3,78. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighed in accordance first with respect to the proportions each of slack, prepared tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

both steam and domestic use during the past few days, but country domestic trade near there has strengthened. As usual, the cheaper coals are most in demand. Standard 6-in. lump is selling there for $3@$3.25, 2-in. lump as low as $2.65 and screenings for $1.40@$1.50. Mt. Olive lump goes to St. Louis in small volume at $4, while the country trade pays $4.50. Mt. Olive coal is moving Northwest rather than into either St. Louis or Chicago.

Kentucky markets are not suffering particularly. Industrial demand is fair and railroads are taking heavier tonnages than they have been because of an active movement of freights. But it is freely admitted that car supply is the thing that is keeping prices fairly firm. The Louisville & Nashville averages 19 per cent and the Illinois Central 43. A threatened breakdown in transportation before March 15 caused by the constantly increasing volume of freight, finally producing various congestions at terminals and transfer points, may hold the market up.

Most Kentucky observers think the low-market of last spring has a good chance of giving a repeat performance. Last year, when a strike threatened, buyers would not buy because they counted heavily on non-union production from eastern Kentucky and a heavy output from the western end of the state whose union mines had a labor contract running another year. On Feb. 1, 1922, the highest priced block coal in the state brought $2.50@$2.75 as against $6 now; screenings, 80c.@$1.25 as compared with $2 today in western Kentucky and $2.75 in the eastern field.

Steamboat companies are again operating the big packets, and the gas and byproduct people are buying some coal. Movement is general to all districts and fairly well scattered. With no weather under 15 deg. above zero for the season in Louisville, volume as handled by retailers has been small, and orders are mostly one and two-ton lots, according to retailers.

Northwest Trade Is Dull

Nothing disturbed the Northwest's trade during the past week except general dissatisfaction with a good deal of the anthracite which has been delivered. So much bone and dirt comes through with it that the Wisconsin Fuel Commission has complained to Senator David I. Walsh of Massachusettes, hoping that the champion of the "peepul" can bring some more pressure to bear upon shippers in the field.

Trade continues light throughout the whole territory, even though prices on the considerable stocks of bituminous at the Head-of-the-Lakes have been eased down a little to draw buyers. Shipments from Duluth-Superior docks one day last week totaled only five cars, which is phenomenal. Dock men there are trying to unload their bituminous stocks but are not pushing their anthracite strongly except to the local trade. There are 32,000 tons of anthracite on hand. The plan is to increase the usual 10c.-a-ton monthly differential on anthracite during the coming spring and summer to encourage warm weather stocking.

The West Flounders Along

Some colder weather made domestic trade a little snappier in most Western markets, but nothing grew really lively. Fair transportation, almost a test to the producers in Kansas, Oklahoma and Arkansas, was largely responsible for a new cut in Kansas lump from $5.50 to $5, and of Arkansas lump from $7 to $6 and Arkansas nut from $5 to $4.

Near Salt Lake City trade picked up ever so slightly for good lump but egg coal and most steam sizes continued to drag bottom. Utah mines are working something less than half time. In Colorado too much lignite was available for market comfort. Prices fluctuated some as they turned downward.

There was a marked weakness in the Ohio coal trade. There were reductions of 25@50c. per ton on mine prices and the tendency at the end of the week was still downward. Production of lump was larger and added to the trouble of producers in finding a market. Retail dealers and consumers at Columbus are buying only for the present and retail prices are falling in sympathy with mine prices. Receipts from West Virginia and Kentucky are increasing in volume. Railroads are taking a fair tonnage and some coal is being acquired by utilities.

Reports from Cincinnati say that the market is on the downward trend, with high-volatile coals the hardest hit. Offerings of spot New River mine run at $4.75 found no takers. River business shows a heavy increase and preparations are being made for increasing the stock piles along the river front.

Production in West Virginia generally speaking did not average over 40 per cent although there was a slight improvement in car supply. The Western movement was larger, more smokeless going forward as a result of the improved car service.

Coal movement on the Charleston Division of the Baltimore & Ohio R.R. was impeded by several slides.

Production figures for the Pocahontas district of West Virginia for the year 1922, as compiled by the Pocahontas Operators' Association, shows a total of 16,130,974 tons, as compared with 13,043,942 tons in 1921, an increase of 3,087,032 tons. The output for 1922 was the largest since 1916. More coal was loaded during the second quarter than in any similar period; loadings were as follows:

First quarter,	3,796,017 tons	Third quarter,	3,605,227 tons
Second quarter,	5,717,129 tons	Fourth quarter,	3,012,601 tons

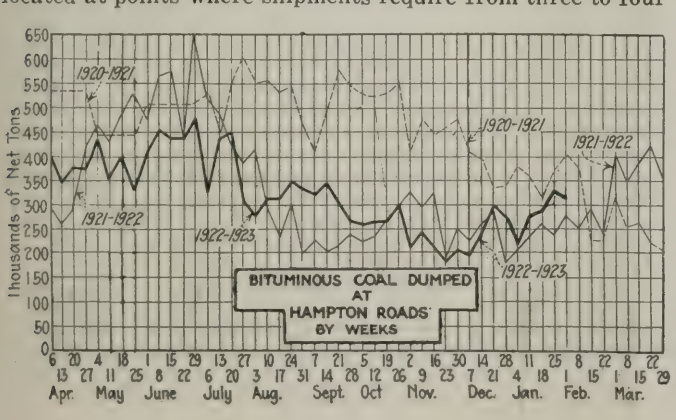
During the week the Pittsburgh Coal Producers Association, the Coal Operators of the thick vein Freeport seam, and the Central Pennsylvania Operators Association signed up with the miners, continuing their wage agreement for another year.

There is much complaint of car shortages in the Pittsburgh district, operators claiming that other industries are better treated, also that the Connellsville region is better served.

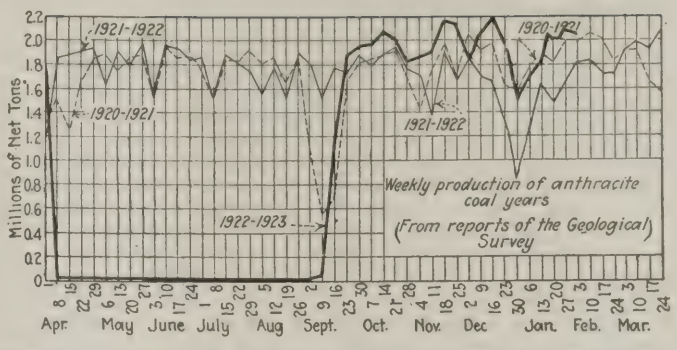
North Atlantic Market Dull

The market in New England is suffering from a lack of buyers. While anthracite receipts are in no greater volume there is notably less anxiety on the part of householders as the calendar moves forward. Inquiry for substitutes is correspondingly less, and since the average retailer feels the situation is less acute he is less and less inclined to buy spot bituminous. In the larger cities there is enough anthracite available in odd sizes to take care of most cases of real distress and many householders have been able on various representations to accumulate enough to carry them through the present season. This all has a distinct bearing on the market for steam grades, for it is roughly estimated that something like 25 per cent of the bituminous that came forward during December was shipped in anticipation of household needs. With this factor subsiding it is clear that the market probably will ease off gradually until April, when prices will settle down on something like a season basis.

Many of the Pocohontas and New River agencies are discouraged over attempts to force spot coal on unwilling buyers inland from points like Boston, Providence, and Portland. Delays in discharging have resulted in serious losses due partly to car shortage but largely to accumulations far in excess of rehandling facilities. There have been cases where boats have been detained three and four weeks at the discharging piers, and any such hardship on the distributor is enough to preclude further efforts in the same direction. Notwithstanding heavy demurrage items current prices on cars Boston have dropped to less than $10 per gross ton, with coal still pressing for sale.



One result is the increased tonnage on wheels at the Hampton Roads terminals. Were there more than scattering demand in this territory we should probably see prices marked off 50@75c. as compared with a week ago, but the volume now actually changing hands is small and what sales there are result from quiet negotiation, with prices hard to follow from day to day. All the shippers have ample coal on hand, even though mining in most cases is less than 50 per cent of normal. There is renewed effort to place coal in the West, now that coastwise prices are less attractive, and contractors are being fed up on their February quotas.



At New York demand is easier and most grades show a lowering in quotations. An occasional cargo of British coal is arriving. A cargo of free Admiralty coal which had arrived there was offered last week at a price higher than domestic coals of good quality could be gotten.

Consumers are not pressing for coal at Philadelphia and are hopeful of lower prices. The railroads seem to be well supplied with fuel and inquiries from this source are few.

Anthracite

The anthracite situation is easier. Demand for the high-priced product of the small operator has fallen off but company coal and the product of the larger independent producers are in strong call. Although there are nearly two months of winter ahead some retail dealers who are located at points where shipments require from three to four

weeks from time of shipment until delivery have cancelled their orders.

The New York State Fuel Administration has received many complaints from consumers of bad preparation of domestic coals and in some instances has ordered the dealer who delivered the coal to either remove or make allowances, at the same time to deliver other coal.

In Baltimore dealers are holding their deliveries strictly to one or two-ton lots but consumers are not able to get the fuel as desired.

"The production of anthracite in the week ended Jan. 27 is estimated at 2,119,000 net tons, including mine fuel, local sales, washery and dredge output," says the Geological Survey. "The nine principal anthracite carriers reported a total of 40,513 cars loaded during that week. When compared with the week preceding this was an increase of about 5 per cent.

"The cumulative production of anthracite for the present coal year (beginning April 1, 1922, to Jan. 27, 1923), stands at 38,675,000 net tons, as against 73,067,000 tons for the same period in the preceding coal year. Thus the present coal year is 24,392,000 net tons, or 47 per cent, behind last year.

"Preliminary reports for the first half of the present week show a slight decline as compared with last week and that the total production will probably be between 2,000,000 and 2,100,000 net tons."

How the Coal Fields Are Working

Percentages of full-time operation of bituminous coal mines, by fields, as reported by the U. S. Geological Survey in Table V of the Weekly Report.

Foreign Market And Export News

Demands for British Coal Increasing; Production Slightly Lower

British coal production for the week ended Jan. 20 was 5,585,000 tons as compared with 5,605,000 tons the previous week, a decrease of 22,000 tons.

The coal industry in Wales is active and the only factor retarding expansion is the question of working hours at the docks. Between 30 and 40 ships are daily unable to secure docking facilities in order to load.

French, Italian and South American demands are increasing. American tonnage has been obtained for transporting 245,000 tons of Welsh coal to the United States.

During the week ended Jan. 12 there were 437,429 tons of coal exported from Cardiff and Newport to the following countries:

	Tons
France	157,343
Italy	66,002
South America	82,720
Spain	25,534
Portugal	12,513
U. S. A.	20,097
British coal depots	41,914
Other countries	31,306
Total	437,429

The effect of the Ruhr occupation on the North English market has been an urgent demand for supplies. The collapse of the mark and the break in the French and Italian exchanges have made business difficult to transact and worry attaches to the fulfilling of orders.

The Swedish State Railways have contracted with Newcastle merchants for 69,000 tons of coal, made up of Northumberland, Durhams, and Scottish.

French Coke Market Active

The occupation of the Ruhr so far has had no influence on the market for French coals, except as regards coke. However, the Saar coal field, which was shipping a good part of its production to Germany probably will divert a portion of these shipments to French destinations.

From Jan. 1 to Jan. 16, inclusive, French blast furnaces have received through the Société des Cokes de Hauts-Fourneaux 174,300 tons of German coke. Coke received before Jan. 16, however, had left the Ruhr before the occupation. On the 16th alone the quantity of coke received was only 4,600 tons.

The interruption in the shipments of German coke resulted in inquiries for French, Belgian and British coke.

French coke ovens have accepted orders to supply to the Société des Cokes de Hauts-Fourneaux 38,000 tons of coke per month at 107 fr. at ovens in the Nord and Pas de Calais and at 112 fr. at ovens in the center of France. Coking slacks, on the other hand, are being sold at 72 fr. in the Nord and Pas de Calais and at 80 fr. in the central coal fields.

Demand at Hampton Roads Slow

Business was dull at Hampton Roads in the face of a falling market brought on, shippers report, through lack of demand due to better car movement and to heavy stocks laid up against a probable April 1 strike of miners which is not now regarded as likely to take place. Movement to New England fell off, although general shipping brought bunkers up to a high plane.

Prices ranged around a figure that makes the prospect for export business brighter. Shippers were keenly interested in the Ruhr developments, having in mind the possibility of entering the foreign market in case Germany's supply of coal is cut off.

News Items From Field and Trade

ALABAMA

The Empire Coal Co., Empire, is about **to construct 40 byproduct ovens** in Walker County near some of the company's holdings, as well as railroads to the undeveloped territory of the company, surveys for which have been made. Walter Moore, of Birmingham, president of the company, estimates that the improvements will cost approximately $1,500,000.

There are 1,196 byproduct coal ovens in Alabama with a yearly capacity of 6,543,000 tons of coal and 4,750,000 tons of coke, according to official figures. Alabama now ranks fourth in the number of ovens and capacity. The byproduct coke capacity was increased in 1922 by the addition of 25 Koppers ovens at the Alabama By-Products Company and 30 Koppers ovens for the Woodward Iron Co.

The Bird Coal & Iron Co., Birmingham, has instituted suit in the courts of Talladega County against the Kuhara Mining Co. and Alexander Tison, of New York, for the recovery of the Talladega furnace property and about 6,000 acres of coal and iron properties in St. Clair and Etowah counties. The properties were acquired by the Bird company about six years ago and leased in 1919 to the Kuhara company, a Japanese corporation, title being vested in Alexander Tison, the lease of the Kuhara company alleged to be for a sufficient period to enable the manufacture of 70,000 tons of pig iron. The original owners are seeking possession of the property and damages for the use of the plant and equipment.

The Stith Coal Co., which has several drift openings at Aldridge, on the Southern Ry., in Walker County, is sinking a 400-ft. shaft to the Black Creek seam, which underlies the America seam, now being worked.

COLORADO

The Mine & Smelter Supply Co., with branches in Denver, Salt Lake City and El Paso, has taken over exclusive representation for the States of Colorado, Utah, Nevada, Wyoming, New Mexico and western Texas for Wilson Plastic-Arc Welders and Wilson Color-tipt Welding Metals.

The lignite output is steadily increasing in the northern field around Erie and Frederick if shipments by Union Pacific are to be taken as a definite indication. An average of 150 cars a day has been reaching Denver, 80 per cent of which stays in that city's territory and the balance is routed eastward as far as Omaha. This road has recently hauled as many as 177 cars a day to Denver. Burlington loadings in the field also are heavy.

Harry F. Nash, vice-president and general manager of sales of the **Alamo Coal Co.**, which has been incorporated in this state, expects to be shipping coal from the Alamo mine by June, 1923. "There is yet much to be done," he says. "A stretch of railroad four miles long must be built to connect the new property with the end of the Loma spur of the Denver & Rio Grande Western, already extending sixteen miles north of Walsenburg; a 600-ft. rock slope must be driven to open up the coal; a 2,500-ton tipple must be purchased, fabricated and erected. Mr. Nash, J. H. P. Fisk, an engineer of Walsenburg, and E. H. McCleary have charge of this construction work. Mr. McCleary is general manager of operations, W. B. Lewis, president; Harry F. Nash, vice-president and general manager; A. S. Pratt, treasurer; George C. Manly, assistant treasurer and counsel, and Howard Willets, comprise the directorate. Mr. Lewis, Mr. Nash, Mr. Pratt and Mr. McCleary occupy the same positions with the Oakdale Coal Co., operating at La Veta. Like the Oakdale, the Alamo will be a strictly domestic mine; it is hoped that the Oakdale record can be equaled—not a single car of run-of-mine coal has been shipped in ten years; the whole output has been sold in prepared sizes. "The new mine is the result of ten years' search for as good a domestic fuel as Oakdale," says Mr. Nash.

Core drilling of the 640-acre, 10,000,000-ton tract has been completed. When the log of the drill showed a depth of 640 ft., a 7-ft. seam was encountered. Sixty-five feet deeper the drill discovered an 11 ft. bed. The coal beds will be exploited through a slope on a 36-per cent inclination conforming to the dip of the coal. The method of mining will not be determined until the main slope has penetrated the coal some distance, when conditions will be better known. The panel system—driving rooms level and panel entries on the pitch, gathering with hoists—is being seriously considered. The mine is to be as up to date as modern equipment and modern methods can make it, underground and on the surface. A tipple, including rotary dump, shaking screens, loading booms and box-car loaders for two tracks, and a rescreening plant have already been designed. Five hundred kilowatts of power-plant capacity will be built as a starter.

CONNECTICUT

The Associated Company, of Hartford, maintaining a corps of inspectors for mines carrying workmen's compensation, has **equipped all its underground men with the new M. S. A. self-rescuer.** The self-rescuer protects the wearer from asphyxiation and afterdamp from explosions and fires. Incidentally, the state mine inspectors of West Virginia also are being equipped with this apparatus.

ILLINOIS

The J. W. Peterson Coal Co., Chicago, has increased its capital stock from $5,000 to $300,000.

The Citizens Coal Mining Co., Springfield, has made a stock dividend of 650 per cent, basing this stock issue on accumulated surplus and undivided profits. The company increases its capital from $60,000 to $300,000.

What is said to be the **largest coal mine electric power contract** ever entered into in Illinois has just been signed at Chicago by the **Central Illinois Public Service Co.** and the **Old Ben Coal Corporation.** The Central Illinois company will supply the entire power requirements of the coal company, which operates twelve of the largest coal mines in Illinois. Three of these mines shipped six million tons of coal last year. The contract is for ten years and the electricity bill of the Old Ben Coal Co. will amount annually to half a million dollars. The Central Illinois Public Service Co. will have an aggregate of 73 mines being operated by electricity obtained from the company, thus making this company one of the largest coal-mine power companies in the United States.

A. R. O'Dell, sales manager for the J. K. Dering Coal Co. of Chicago is spending two weeks in the Northwest developing trade.

The **Ernest Coal mine**, known as **Franco No. 2** at Harrisburg, recently **broke its hoisting record** when 3,301 tons of coal were hoisted in eight hours. The record is 200 tons over the previous record of the mine and is considered good, inasmuch as the cars used underground at this mine are of only 2-ton capacity, while other mines in the district use from 3- to 5-ton mine cars. **Mine No. 2** of **Big Creek Coals, Inc.**, near Ledford, also recently hoisted 2,363 tons in one day's work, which makes a new mark for this plant. The mine is well known also under the name of the Steel Tipple Mine.

Work has been begun upon **installing two new cages at the Peerless Coal Co.'s** mine at Springfield. The old cages were demolished when they crashed to the bottom of the pit. A broken sheave wheel caused the accident.

The Conveyors Corporation of America, Chicago, has acquired from the Green Engineering Co., East Chicago, Ind., all rights to the **Green steam jet ash conveyor.**

George W. Gosnell, Herrin, formerly county mine inspector for the Twelfth district, comprising Williamson and Johnson counties, **has been appointed state mine inspector** by Governor Small. He succeeds W. L. Morgan, Greenville, recently named state mining investigator.

A reorganization in the Nason coal interests was completed Dec. 30, 1922. All mining and field operations were consolidated under the name of the **Illinois Coal Corporation**, and the capital was increased from $1,000,000 to $10,000,000. The name was changed from the Illinois Coal & Coke Corporation Dec. 26 and the **Nokomis Coal Co.** merged with the corporation. The **Nason Coal Co.**, of Chicago, continues to be the selling company.

Fire recently caused a loss estimated at from $15,000 to $20,000 at the mine of the **Randolph Mining Co.**, at Coulterville. The flames originated in the wash house of the plant and before they could be checked had completely destroyed the boiler house and engine room, which were located near the wash house. Over 100 men are employed at this mine, most of whom will be idle until the destroyed buildings have been rebuilt.

Messrs. Hartshorn and Norman, of Danville, who are identified with the **Hartshorn Coal & Mining Co.**, with headquarters in that city, recently spent some time at Elkville, the location of their new slope and strip operations. The concern recently acquired large tracts for mining purposes near Elkville and are rapidly completing the work of setting up machinery, building tracks, etc., preparatory to producing coal. The company will operate both slope and stripping operations and will employ several hundred men when running full capacity. With the work progressing as it now is, it is expected that coal will be hoisted in from 60 to 80 days.

The Chain Belt Co., Milwaukee, announces the appointment of **Fitch S. Bosworth** as manager of the Chicago office. Mr. Bosworth has been in charge of the Chain Belt Co.'s St. Louis office for the last three years and has specialized on chain and conveying engineering problems. With him will be associated **Raymond X. Raymond**, who for several years has been connected with the export sales department in Milwaukee. **Thomas F. Scannell**, formerly of the Chicago office, has been placed in charge of the St. Louis office.

INDIANA

The Madison Mining Co. at Crown Point has filed a preliminary certificate of dissolution with the Secretary of State.

Production of mines in the Indiana field is averaging about 50 per cent of normal. Many of the mines are operating only two or three days a week, but others, especially in the Fourth vein, have operated almost full time. Mines in the northern part of the field have had better work since the first of the year than in any other part of the district. Some mines have had idle days because of car shortage, but the greatest detriment is lack of demand.

Miners in Indiana would not be required to qualify with a local board in each county where they work under the provisions of a bill recently introduced in the Indiana General Assembly. The bill seeks to repeal the miners' license law passed in 1911, which provides that any applicant for work in a mine must undergo an examination by a board of three members. Two members of the board can be named by the local labor organization in the county, under the law, and the other is an operator. Representative Isaac H. Hull, of Laporte and Starke counties, in introducing the bill said that although the 1911 act was passed ostensibly to protect miners against injury by refusing work to those not physically qualified to work, in actual effect it prevented men from working who were not members of labor organizations.

A. E. Bradshaw, formerly president of the National Building Supply Dealers' Association, and now head of the Allied Coal & Material Co., of Indianapolis, one of the largest retail coal and material supply companies in Indiana, has been named chairman of the retail committee of the Indianapolis Chamber of Commerce.

Fuel conservation problems were discussed by 150 power-plant managers and engineers who met recently at Purdue University, Lafayette, the object of the conference being to promote economy in the use of fuel in power plants. Professor G. A. Young, of Purdue, said that the nation never would be as great as its resources justified until the consumption of coal had been reduced and a greater amount of energy produced from a given consumption of fuel. R. H. Gardner, superintendent of the Northern Indiana Gas & Electric Co., said that large central power stations were more economical than a number of small plants and that centralization should be encouraged for the sake of fuel economy.

The erection of the first coal washery in Indiana is still under consideration by the J. K. Dering Coal Co., of Chicago, for its No. 8 mine at Clinton, where the company is operating in the No. 3 seam, a very difficult coal to prepare properly, but the plans have not been approved largely because of the initial cost, which would be in the neighborhood of $300,000.

IOWA

J. L. Coombes, formerly mining engineer at Lynch mines, Kentucky, is now located at Cedar Rapids, and is engaged in construction business.

KANSAS

Eight diamond core drills and one standard drill are testing the territory three miles west of Oswego for coal. A new mammoth power plant is going up on the river and excavating is almost completed.

KENTUCKY

The Pond Creek Coal Co., acquired recently by Henry Ford and his associates from T. B. Davis and his associates, **will hereafter be known as the Banner Fork Coal Corporation**, that being the name of the company under which the Ford mines in the Hazard Kentucky field are operated. Edsel B. Ford is president of the Kentucky corporation.

The Kentucky & West Virginia Power Co., of Logan, W. Va., is preparing to expend $750,000 in enlarging its plant and in constructing about 125 miles of high tension line to the Hazard field of Kentucky.

Thirty-five miles of railroad connecting Harlan County, Kentucky, and Lee County, Virginia, **is to be constructed by the Southeastern Ry. Co.**, according to articles of incorporation filed Jan. 16 at Frankfort by that company. The new line will connect with the Southern Ry. near the west of Keokee, Va., and with the Louisville & Nashville on Clover Fork. The company is capitalized at $500,000 with L. O. Pettit, Big Stone Gap, Va., as president; W. A. Hahn, Norfolk, Va., vice-president; J. F. Bullitt, Jr., Big Stone Gap, secretary, and C. R. Carver, Norfolk, treasurer. Headquarters of the company will be at Big Stone Gap.

Press reports state that the Democratic party in Kentucky is planning to run **John E. Buckingham**, of Ashland, as a business man for governor of the state. Mr. Buckingham is a big operator, who for years has been connected with the John C. C. Mayo Consolidation, Elkhorn Coal Corporation and other interests.

Good rises in the Ohio, Kentucky and other rivers of the state is resulting in coal movement opening again, as there is no ice in the rivers, and the water is at the best boating stage of some weeks. The Pittsburgh Coal Co., of Louisville; Dugan Coal Co., Slider Coal Co. and others are anticipating shipments. The Inland Waterways Co. has been moving considerable tonnage in from Kentucky River mines.

MASSACHUSETTS

The coal shortage in Massachusetts is practically over, according to figures presented recently by James J. Phelan, Emergency Fuel Administration for the state. Except for one week, since mining was resumed, production of anthracite has shown a substantial increase over that of 1921.

MINNESOTA

A survey of the coal situation through Minnesota has been published with statements of coal supplies from about one-third of the counties of the state, representing all directions. Almost without exception, hard coal is reported very short or totally exhausted, and soft coal is sufficient for the remainder of the winter. In the timber district, wood has helped out and in the west considerable lignite has been used.

E. E. Heiner, of the Superior Coal & Dock Co., has been in Duluth recently inspecting the company's enlarged dock there. Mr. Heiner asserts that the improved handling facilities made **the dock the fastest at the Head of the Lakes.**

Charles Beuglet, sales manager for the Northwestern Fuel Co., has left Duluth for a month's stay in Florida.

Ivan Bowen, **State Fuel Administrator**, has submitted a report to Governor Preus, in which he **recommends state control of the fuel trade** through a system of licensing, and a supervision of grades. According to the report, fuel should be sold by grades based on heat units, not on weight. A bill is suggested to cover this, and would provide that the governor might declare an emergency which would give power to supervise, regulate and control receipt, storage, purchase, sale, use, distribution and delivery of fuel. The railroad and warehouse commission would have power to examine all books of the various coal companies and ascertain where all coal was delivered, investigate prices by all concerned.

MISSOURI

Stewart-Thill Co. is the new name of the Walter L. Flower Co., of St. Louis, district representatives of the Conveyors' Corporation of America, Chicago. The personnel of the organization remains the same.

The **Wickham Coal Co. at St. Louis has liquidated and quit.** In 1897 E. F. Wickham organized this firm and was succeeded at his death by W. F. Wickham. In its day it was a factor in the movement of big tonnages. Ill health forced W. F. Wickham to retire. He is in California for the winter.

W. F. Heinecke, prominent in retail and jobbing circles in St. Louis, is in Florida on a two months' vacation for his health.

The Federal State Crop Reporting Service for Missouri reports from Jefferson City for 1922 that Missouri farmers estimate that 72 per cent of their fuel for 1922 was wood and only 28 per cent coal. They figure on using 14 cords of wood during the season at $3.40 per cord, or $3.10 when cut stove length. The farmers who bought coal nearly altogether a few years ago, when the price was reasonable, have now gone back almost entirely to wood.

Missouri branch of the United Mine Workers of America has elected the following officers: President, Arch Helm; vice-president, James Colley; secretary and treasurer, George Hepple. Andres Steele, of Novinger, was renamed as national board member. A. G. Llelwellyn, of Novinger, was chosen sub-district board member to succeed L. E. Medlin, of Kirksville.

Carl Hirdler, traffic manager for the Wallace Coal Co., is spending a three months' health trip at St. Petersburg, Fla.

MONTANA

The mine of the **International Coal Co.**, Bearcreek, has been taken over by a new corporation known as the **Carbon County Coal Co.**, of which Merrill Nibley of Salt Lake City, Utah, is president. McCandles Moffitt is in active charge of the mine. Mr. Nibley formerly was general manager of the Utah-Idaho Sugar Co. Mr. Moffitt was employed by the American Fuel Co. of Utah and later by the Standard Coal Co. of the same state. The International mine has been closed down for some time, but Mr. Moffitt is rapidly reconditioning it.

NEW JERSEY

At a special meeting Jan. 26 of the Board of Directors of the **Taylor-Wharton Iron & Steel Co.**, High Bridge, **Percival Chrystie** was elected president to succeed the late Knox Taylor. Mr. Chrystie was formerly vice-president and has been acting president since Mr. Taylor's death.

NEW YORK

At a meeting of the board of directors of the **Coal & Iron National Bank of the City of New York** held Jan. 25, John T. Sproull was elected chairman of the board of directors, resigning the office of president. Mr. Sproull was one of the organizers of the bank in 1904, since which time he has acted as president. Julian W. Potter was elected president, effective Feb. 1. Mr. Potter is a Southern banker who came to New York from Bowling Green, Ky., where he was vice-president of the American National Bank.

In transporting anthracite **the railroads have surpassed by more than 18 per cent, their record last year.** Robert S. Binkerd, vice chairman of the Committee on Public Relations of Eastern Railroads, declared Feb. 1 in making public a letter to Health Commissioner Copeland, taking issue with Dr. Copeland's statement that the coal shortage in New York City was due to the inability of the carriers to move coal as a result of the railroad shopmen's strike. Mr. Binkerd gave out figures from the U. S. Geological Survey, showing that since the resumption of mining on Sept. 11, 1922, up to and including Jan. 20 of this year, the anthracite-carrying railroads had handled 36,052,000 tons of coal as against 30,517,000 tons in the corresponding period of 1921-1922.

Wages of longshoremen loading coal in the Port of New York have been increased from $6 a day to $6.50 a day in the new contract between the coal handlers and the Coal Merchants' Association. The longshoremen based their demand on higher cost of living and the merchants admitted their request was reasonable and granted it without argument.

Coal truckmen of New York City who have been doubling and trebling legal rates to peddlers, who in turn passed the increased cost along to consumers have been warned by State and City Fuel Administration officials that continuation of this practice will bring prosecution. Seventeen alleged offenders were summoned to General Goethals' office to answer to complaints received by the State Fuel Administrator that they had **increased their rates from the legal $1.50 a ton to $3 and $4 a ton**, and that, the peddlers passing this increase along to private customers, the public was the sufferer from the truckmen's illegal practices. The truckmen were questioned by General George W. Goethals, State Fuel Administrator; C. W. Wickersham, counsel to the administration, and Administrators Eltz for Manhattan and Foster for the Bronx.

Pilling & Co., Inc., announce the election of Frank J. Herman, manager of coal sales, and Ralph W. Clark, manager of pig, iron sales, as directors, effective Jan. 1, 1923. During the past few months Pilling & Company, Inc., has expanded its coal selling organization greatly. A Johnstown, Pa., office was opened Oct. 1, in charge of Charles S. Martin. Bruce N. Stimets and J. B. McGolrick (who was formerly with Karm Terminal) are serving the northern New Jersey coal buyers. W. T. Miller, until recently with Pardee Brothers, is selling for them in New York State and is making his headquarters in Utica. The company also expects to open a Boston office within a short time

Senator Mortimer Ferris, of Plattsburg, tried unsuccessfully Feb. 1 to have the Senate adopt a resolution calling to the attention of the State Fuel Administrator the assertion that coal is being shipped through New York State to Canada, where it is delivered to **customers who are willing to pay $20 and $25 a ton** at the mines. Senator Ferris' resolution would have called upon the Fuel Administrator to impound such coal and distribute it at reasonable prices in New York.

William Fellows Morgan, president of the United Hospital Fund, announced that several of the hospitals in New York City are **considering abandoning the use of coal and substituting oil** for fuel. A saving of from 20 to 30 per cent can be effected, it is believed.

OHIO

George H. Merryweather, of the Waubon Coal Co., of Chicago, secretary of the American Wholesale Coal Association, and **I. C. Cochran**, managing director of the same organization, visited Columbus wholesalers Jan. 31 and were **entertained at luncheon** at the Chittenden Hotel. About two score were present and the question of organizing a closer association of wholesalers and producers and possibly retailers was taken up. A committee consisting of P. A. Coen, W. J. Hamilton, Jay Miller and M. L. Yuster was named to devise ways and means for the organization. It was decided by the committee to revive the noonday luncheon and later organize a coal association which would have for its members all of the coal industry. The question of making reports to the U. S. Coal Commission was discussed at the open meeting and reports showed that some jobbers had refused to make the reports desired. It was the consensus of opinion that the reports should be made in order to help the investigation of the Coal Commission.

E. M. Long and his two sons have **purchased three operating mines and 152 acres of coal lands** and six miles of spur track from the Short Creek Coal Co., Cadiz. The consideration was in the neighborhood of $3,000,000. The mines have a production capacity of 85,000 tons yearly.

The Southern Ohio Pig Iron & Coke Association held its annual meeting at Ironton, Jan. 24. The primary object was to get the views of the members on the coal question, with the idea of presenting the case of steel and furnace operators having their own coal mines, coke plants and cars, before the U. S. Coal Commission. After a lengthy discussion it was felt that little could be gained by this movement, and the discussion reverted to how best to insure a regular supply of good quality coal for coking and other purposes.

PENNSYLVANIA

In an opinion by Justice Simpson, the State Supreme Court on Jan. 29 affirmed the judgment of the Court of Common Pleas of Schuylkill County **denying an in-**

junction in the suit of Calvin Pardee and about forty other coal-land owners to have the county and the county commissioners enjoined from sitting as a board to "revise, raise and equalize the valuation of all property" returned by the local tax assessors. This decision means that the attack on the method has been ruled out, without prejudice to appeals from specific valuations on their merits.

For a consideration of $46,000 the entire rights of the Dolph estate to the **coal under the land in a 60-acre tract in the Borough of Olyphant have been surrendered to the Hudson Coal Co.**, the deed having been filed Jan. 29. The indenture was executed on Dec. 19, 1922, between the officials of the company and the owners of the land. The land under which the coal rights were sold is bordered on the north, south, east and west by property of the coal company. With the coal rights, the company purchased freedom from all claims for "negligent mining or negligent preparation of coal."

The Tri-District Board of the United Mine Workers of America in the anthracite fields **has decided to maintain a lobby committee at Harrisburg**, made up of one member from each district and as many more as may be necessary. It will also wage a fight against the movement started in Philadelphia to repeal the miners' certificate law, and will ask that it be extended to the bituminous fields.

William L. Connell, of Scranton, has been granted a leave of absence of six months from his duties as chairman of the Anthracite Conciliation Board. W. W. Inglis, president of the Glen Alden Coal Co., has been selected by the operators of District No. 1 to represent them on the board during his absence.

P. S. Gardner, of New York City, has taken over the old Neilson colliery at Shamokin, which has not been operated for a number of years. J. G. Hayes, of Scranton, is general manager.

The Monroe Coal Co., operating at Revloc, Cambria County, **gave prizes to its miners as an incentive to stimulate coal production during December.** Six watches were offered on a basis of merit to the best heading man, best room loaders and best cutters and scrapers. George Kirkis and Wisel Smalley won first and second prizes as room loaders, they loading 259 and 245 tons, respectively. The first prize to a heading man was won by Philip Cevallers, whose yardage for the month netted him wages amounting to $366.64 and a prize watch. John Yulius won second with a yardage which netted him $360.64 and a watch. The cutters and scrapers worked in pairs and John Yenovitch and Vincent Blaznick carried off the prizes and a nice return in wages, their aggregate output being 3,539 tons. Six suits of clothes will be awarded for the month of January.

Seward E. Button, former state mine chief under the Sproul administration, has been appointed **general superintendent of the Temple Coal Co.**, with headquarters at Scranton. Before becoming state mine chief Mr. Button was in the Temple service.

A bill has been introduced in the Senate at Harrisburg by Senator W. I. Stineman, Cambria County, "to protect bituminous coal miners in the determination of the amount of coal to be used as a basis for calculating wages." The measure provides that any miner shall be entitled to receive or, failing to receive, then **to collect by due process** of law at such rates as may have been agreed upon **full and exact wages for the mining of all merchantable coal he mines.** Seventy-six pounds is deemed one bushel and 2,000 lb. net as a ton. All cars must be uniform in capacity at each mine and no unbranded cars are allowed to enter a mine for longer than three months without being branded by the mine inspector. Violation of this provision subjects the owner to a fine of $1 a car for each day the car is unbranded. The bill also provides that at every bituminous coal mine where coal is mined by weight or measure the miners may employ a checkweighman or checkmeasurer who is to be given access to the mines and shall not be considered a trespasser. A fine of $20 to $100 is provided for violations of this provision.

Senator Berntheizel has offered a bill in the State Senate **repealing the act** of May 25, 1921, creating a state board for the **registration of professional engineers and land surveyors.** The bill has gone to the Judiciary General Committee.

Before the embers of the Chauncey breaker, destroyed by fire Jan. 27, were extinguished, George F. Lee, president of the George F. Lee Coal Co., had given the **contract for a new breaker** to E. E. Reilly, of Kingston, and undertook **to resume production in 90 days.** The breaker, at Avondale, was found on fire Sunday morning by repairmen. The fire began at the top and was so far advanced when discovered that extinguishers were not effective. About 400 tons of coal in the bins were destroyed. The burned breaker was of wooden construction, was electrically operated, and had a daily capacity of about 1,000 tons.

Representative Wilson G. Sarig, Berks County, minority leader of the House, has introduced a bill **to repeal the anthracite tax law** of 1921. The repealer is brief, merely quoting the title of the tax law and providing that it be repealed. The measure is one of the Democratic bills agreed to by the minority members at caucus as their legislative program.

SOUTH DAKOTA

The Homestake Mining Co., of Lead, which probably is the greatest operating gold mine in the world at the present time, has acquired a considerable acreage of coal land near the Shields mine at Gillette, where a model town site has been laid out and arrangements made for opening in the spring a stripping operation.

TEXAS

C. W. Osborne, of Dallas, president and manager of the O. K. Lignite Co., has made arrangements to develop 600 acres of coal land near Garrison. The company is now making arrangements to install a hoisting engine and small boilers, as well as mine cars, and it is estimated that the daily output will be five carloads.

UTAH

It is expected that the **International Mine Rescue and First-Aid Convention** will be held in Salt Lake City this summer.

The coal industry of Utah has a representative in the Legislature. He is **John E. Pettit**, superintendent of the Panther mine of the U. S. Fuel Co. in Carbon County. Mr. Pettit is a member of the House of Representatives. He has been state coal mining inspector twice.

VIRGINIA

W. N. Westerlund, assistant manager of the Norfolk office of Hasler & Co., has gone to New York to take charge of the office there. Richard Hasler has come to Norfolk from the New York office to fill the vacancy made by the transfer of Mr. Westerlund.

The Steinman Coal Co., of Steinman, whose post office address is Tandy, Va., has perfected an incorporation with a capital of $300,000. The following officers have been elected: President, James H. Steinman, Lancaster, Pa.; secretary, Whitney C. Faulkner, Richmond, Va.

WEST VIRGINIA

With the transfer of the records in the murder trial of C. Frank Keeney, president of District 17, United Mine Workers of America, from Jefferson County to Morgan County, all arrangements for the **beginning of the case, Feb. 20**, have been completed. It is scheduled to start on Feb. 20. The state will have about 125 witnesses and the defense about 75.

The Monongah Fuel Co., having recently acquired a large tract of coal land adjacent to its present mine on Kuhn's Run, in the Marion County field, **has completed plans for the installation of a plant with a capacity of between 1,500 and 2,000 tons a day.** The contract for the installation of electrical equipment, including substation, was awarded to the Fairmont Electric Service Co. The fuel company expects to install three 75-kw. 222,000-volt to 2,200-volt transformers, 100-kw. motor generator set, 25,000-volt switch, 25,000-volt lightning arrester, one steel substation tower. The apparatus will be of the Westinghouse type. The Monongah Fuel Co. has as its head David Victor, who is also general manager.

Shaker-screen equipment of the most modern type **was recently installed at the Eureka Mine** of the Consumers' Fuel Co., Randall, near Morgantown, by the Fairmont Mining Machinery Co., Fairmont. The Eureka Mine, which is one of the Bertha Coal Co. interests of Pittsburgh, Pa., now has a rating of sixty-four cars per day and with the new equipment it is hoped to develop a rating of one hundred cars daily. The Bertha Coal Co. is planning to install shaker-screen equipment at most of its large operations this year with a view of doubling production in 1923.

The Cumberland Iron Works, of Westmoreland, near Huntington, which has been operating only about three months, has been awarded a contract by the Ford coal interests for the manufacture of **several hundred mine cars for the Nuttallburg mine**, near Thurmond, in the New River field at which new machinery is being installed throughout.

WISCONSIN

A. W. Berresford has resigned as vice-president and director of the Cutler-Hammer Co., Milwaukee. Mr. Berresford's request to be released was based entirely on personal consideration. Arrangements have been made whereby his services become available in specific matters.

CANADA

Trouble between operator and employee persists in some of the fields of Alberta. The mines in and around Edmonton, it is stated by the operators, are all working with full crews and without complaint. At a recent meeting, however, it was admitted that the present situation was unsatisfactory to the public because of the expenditure by the city for police protection. On behalf of the operators it was stated that no objection would be offered to workers joining the United Mine Workers. An official of the Edmonton Trades and Labor Council declared that there were some 12,000 miners in the province of Alberta of whom about 10,000 were union men. Completion of the organization, he said, would result in the stabilization of the industry, which was what the miners wanted. Statements followed from a number of the operators. The sentiment was strongly favorable to making every possible effort to arrive at a basis for an amicable settlement of the issues in dispute.

WASHINGTON, D. C.

Bids are solicited for the transportation of one cargo of 4,000-6,500 tons of Navy coal from Hampton Roads, Va., to the Navy Supply Depot, South Brooklyn, N. Y., in vessel of **American registry**. The loading date at Hampton Roads will be between Feb. 17-20, both inclusive. Tenders will be opened at noon Feb. 12.

The Chamber of Commerce of the United States has announced the appointment of **A. B. Barber**, of Portland, Ore., as **manager of the chamber's department of Transportation and Communication.** He succeeds J. Rowland Bibbins, who resigned to take up private engineering practice.

The U. S. Supreme Court has **declined to issue a writ of certiorari sought by the S. H. Benjamin Fuel & Supply Co.** to review the decision by which it lost a suit against the Bell Union Coal & Mining Co. in which breach of contract for delivery of coal had been alleged, thus permitting the decisions of the lower courts to stand. As presented by attorneys for the Benjamin company the question involved was: "Where there is a contract for the sale of goods with instalment deliveries, each instalment to be paid for on a specific date after each delivery, does the failure of the buyer to pay an instalment promptly on the date due give the seller the right to cancel the contract unless the buyer's failure, coupled with other circumstances, indicates an intention on the part of the buyer to breach or abandon the contract or shows his inability to perform the same?" The Benjamin Company entered into a written contract with the Bell mining company in April, 1920, to purchase 25,000 tons of 2-in. screenings and 25,000 tons of prepared coal, to be delivered in equal monthly shipments from May, 1920, to April 1, 1921, at $2.50 per ton for the screenings and $3.50 per ton for the prepared coal. The Benjamin company alleged that only a small part of the shipments were made in May, June and July, and that in August the Bell company canceled the contract, alleging failure to pay on time. The Benjamin company declared that its payment for June delivery, due July 15, was mailed by check July 19 and that the delay was due to inability to get exact weights from the mine in Union County, Kentucky. The price of coal advanced steadily and rapidly in the summer of 1920 and in September the Benjamin company filed suit in the U. S. district court for eastern Pennsylvania, seeking judgment of $300,000. There was a second contract for delivery of 25 carloads, of which 9 carloads were delivered, and on this contract a jury gave the Benjamin company $2,016. The Court instructed the jury that as to the larger contract the Benjamin company had breached the contract by failure to pay on time. The Circuit Court of Appeals sustained this and now the Supreme Court has declined to review the case.

Traffic News

A report on the condition of locomotive equipment just filed by the Pennsylvania R.R. with the Car Service Division of the American Railway Association shows that on Jan. 1, 1923 **nearly 80 per cent of the road's locomotives were in good order.** Out of 7,249 steam locomotives on the system, the percentage of all classes out of service for repairs was only 21.44. On Jan. 1, 1923, fewer locomotives requiring heavy repairs were out of service than on Jan. 1 a year ago. In the same period the out put of the company's shops increased to such an extent that the number of freight cars requiring repairs was reduced to about 7 per cent of the cars on the line. Fewer freight cars were out of service under and awaiting heavy repairs on Jan. 1, 1923, than on Jan. 1, 1922.

The Montana Coal & Iron Co. has filed with the I. C. C. exceptions to the proposed report of Attorney-Examiner M. A. Pattison, in what is known as the "Western Coal Rate" case (Docket 13588). The report recommends many revisions in the rates on anthracite and bituminous coal from mines in New Mexico, Montana, Wyoing, Colorado and other western states. Hearings were held in many western cities and extended over several months.

Authority has been granted by the Interstate Commerce Commission to the Van Sweringen group of Cleveland, which now controls the New York, Chicago & St. Louis R.R. and other lines in the Middle West, **to take over control of the Chesapeake & Ohio** by assuming seven places on its board of directors. O. P. Van Sweringen and six of his associates, who recently announced they had acquired a majority of the common stock of the Chesapeake & Ohio, may now become directors of that raliroad, and will control seven out of nine votes upon the board. Commissioner Eastman dissented from the commission's action, but all other members of the commission approved the order. M. J. Van Sweringen, J. J. Bernet, Otto Miller, J. R. Nutt, C. C. Bradley and W. A. Colston are the others permitted by the order to go on the board.

Preliminary action has been taken by several companies operating in smokeless territory and served by two railroads **to annul the recently adopted rules and regulations governing the rating of mines known as joint-service mines.** Parties to such an action are the New River Coal Co., the White Oak Fuel Co., Stuart Colliery Co., Dunloop Coal & Coke Co., Beckley Coal & Coke Co., Mabscott Coal & Coke Co. and the Cranberry Fuel Co. These companies have filed suit in the U. S. Court for the southern district of West Virginia against the Chesapeake & Ohio Ry., the Virginian Ry., the United States of America and the Interstate Commerce Commission. The plaintiffs in this case seek to have the new rule which prohibits joint service mines from receiving 150 per cent car supply set aside and annulled. Heretofore, mines in a position to ship by two roads have been entitled to a 75 per cent car supply from each road as against a 100 per cent rating for mines shipping one way. The first hearing on the case was held at Richmond, Va., on Feb. 6.

Association Activities

Northeast Kentucky Coal Association

The fifth annual meeting of the Northeast Kentucky Coal Association held at Ashland, was one of the most successful and most largely attended in the annals of the association, 85 per cent of the tonnage of the district being represented. All of last year's officers were re-elected as follows: C. W. Connor, of Esco, president; E. R. Price, of Van Lear, first vice-president; E. L. Bailey, of Hellier, second vice-president; George B. Archer, of Prestonburg, treasurer; C. J. Neekamp, of Ashland, secretary.

Many subjects of vital interest were discussed, among the most important being that having to do with car supply. J. D. Battle, traffic manager of the National Coal Association, in an address stated that the Interstate Commerce Commission had approved in principle the mine-rating rules recently proposed by the joint conference of operators and railroad officials and that the carriers and the operators will carry out the suggestions made by the conference.

At the banquet of the Ashland Chamber of Commerce given in honor of visiting operators, over which John E. Buckingham presided as toastmaster, a number of officials of the Chesapeake & Ohio Ry. were present and made brief addresses, among them being F. M. Whitaker, vice-president in charge of traffic; J. B. Parrish, general manager; E. D. Hotchkiss, freight traffic manager. Another prominent railroad official present was W. G. Curren, general superintendent of transportation of the Baltimore & Ohio, who pointed out the steps being taken by his company toward bettering transportation conditions. J. D. A. Morrow, former executive vice-president of the National Coal Association, discussed the trend of radical legislation, and Lawson Blenkinsop, chief of the State Department of Mines, addressed himself to the efficient operation of mines. President C. W. Connor, of the association, spoke of the rapid development of the Big Sandy region and of the certainty of further development in view of the quality of coal produced in the region.

Monongahela Coal Association

At the annual meeting of the Monongahela Coal Association held in Morgantown on Jan. 12, largely attended by members, officers were elected and directors chosen. Operators on the Monongahela River between the Pennsylvania State line and Fairmont on the south constitute the membership of this association The new roster of officers includes: John Hay Johns, of Pittsburgh, Pa., president; E. H. Gilbert, Morgantown, vice-president; J. B. Hanford, Morgantown, treasurer. In the list of directors chosen were B. M. Chaplin, Morgantown; Whitney Warner, Cleveland; W. H. Soper, Morgantown; A. O. Davis, Uniontown; Robert Grant, Boston, Mass.;; George S. Connell, Connellsville; Samuel D. Brady, Fairmont; Vincent E. Gocke, Clarksburg; R. N. Davis, Morgantown; Dr. W. R. Mitchell, Morgantown, and W. E. Watson, Fairmont. Mr. Watson was president of the association last year.

Obituary

Rastus S. Ransom, Jr., president of the Ransom Engineering Company of Hazleton, Pa., a graduate of Colorado School of Mines, Class of 1913, was accidently killed while cleaning his revolver on the afternoon of Jan. 18. Funeral services were held from his late home in Hazleton. Interment was in Rosedale Cemetery, Orange, N. J. After his graduation he practiced his profession in Utah and Colorado. In 1915 he returned to the East and became interested in research work and invented a new type of coal jig which he manufactured and was meeting with marked success in the Pennsylvania coal fields. He was a member of the American Institute of Mining Engineers. He is survived by his wife and a daughter.

William P. Waugh, consulting engineer for the H. H. Robertson Co., of Pittsburgh, and known from coast to coast through his development of skylights and the solution of ventilation problems for many of the country's greatest industrial plants and public buildings, died at his home at Sewickley, Pa., on Jan. 15. He is survived by his wife and two daughters.

Frederick Schwaim, formerly head of the F. Schwaim Coal Co., Sioux City, Ia., died Jan. 13 at his home in Sioux City. He was born in Germany, May 2, 1848. He came to the United States at the age of seventeen and first lived in Champaign, Ill. In 1887 he located in Sioux City and for years had been identified with the coal trade there, retiring fifteen years ago.

Henry Melville Whitney, known as one of the greatest captains of industry of his time, died at his home in Brookline, Mass., Jan. 25, at the age of 84 years. Until his retirement several years ago from active affairs he was an international figure as capitalist and transportation magnate. As organizer of the Dominion Coal Co., from which grew the present coal and iron industry of Cape Breton, N. S., it had been said of him that "no American ever did more for Canada."

Western Kentucky operators, jobbers and many consumers have heard with regret of the death of **A. C. Lackey,** of Nashville, Tenn., on Jan. 29, death being due to asthma, from which he was a chronic sufferer. Mr. Lackey was president of the Douglas Coal Mining Co., western Kentucky; the Phoenix Coal Mining Co., which he just recently acquired, also in western Kentucky, and the Dixie Fuel Co., jobbers, with offices at Louisville, Nashville and Chicago. Louisville was the headquarters of the two mining companies. Mr. Lackey is survived by his wife, a daughter and a son.

Coming Meetings

Northern West Virginia Coal Operators' Association will meet Feb. 13 at Fairmont, W. Va. Secretary, G. S. Brackett, Fairmont. W. Va.

American Institute of Mining and Metallurgical Engineers will hold its annual meeting Feb. 19-22, 1923, at the Engineering Societies Building, New York City. Secretary, F. F. Sharpless, New York City.

International Chamber of Commerce will hold its second general meeting in Rome, Italy, March 19-26.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

National Foreign Trade Council will hold its annual conference April 25-27 at New Orleans, La.

Pittsburgh Vein Operators' Association will hold its annual meeting Feb. 12 at the Hotel Cleveland, Cleveland, Ohio. Secretary, D. F. Hurd, Cleveland, Ohio.

The Upper Potomac Coal Association will hold its annual meeting Feb. 10 at Cumberland, Md. Secretary, J. F. Palmer, Cumberland, Md.

Northwestern Pennsylvania Coal Operators' Association will hold its annual meeting March 6 at the William Penn Hotel, Pittsburgh, Pa. Secretary, T. F. Diefenderfer, Butler, Pa.

Canadian Institute of Mining and Metallurgy's annual meeting will be held March 7, 8 and 9 at the Mount Royal Hotel, Montreal, Quebec, Canada. Secretary, George C. Mackenzie, Montreal, Quebec, Canada.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., Dec. 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

Indiana Bituminous Coal Operators' Association will hold its annual meeting March 14 at Terre Haute, Ind. Secretary, P. H. Penna, Terre Haute, Ind.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

American Institute of Mining and Metallurgical Engineers, New York Section, will hold its annual meeting at the Chemists' Club, 52 East 41st St., New York City, Feb. 14. The subject will be: Present Anthracite and Bituminous Coal Situation. Secretary, E. L. Gruver, 20 Broad St., New York City.

Southern Appalachian Coal Operators' Association will hold its annual meeting Feb. 23 at Knoxville, Tenn. Secretary, R. E. Howe, Knoxville, Tenn.

The executive board of the **Coal Mining Institute of America** will meet in Pittsburgh, Pa., Saturday, March 3.

The Gas and Fuel Section of the American Chemical Society is arranging a second sectional meeting at the New Haven meeting of the American Chemical Society during the first week in April. The section program will consist of papers on gas and fuel chemistry and a symposium on motor fuels, held jointly with the petroleum division.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10. Meetings of the National Council will be held morning and afternoon of the first day for nomination of directors. Seventeen directors are to be elected for a term of two years each. On the mornings of May 8, 9 and 10 and on the afternoon of May 10 there will be general sessions devoted to the subject of "Transportation in All Its Phases in the United States." On the evening of May 8 a general session will be devoted to European conditions from the American viewpoint, and in the afternoon there will be group meetings on civic development, domestic distribution, fabricated production and finance. On the afternoon of May 9 there will be group meetings on foreign commerce, insurance, natural resources, production, and transportation and communication.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Pooling Coal and Cars

WAR-TIME experience in pooling coal and railroad cars has not made enthusiasts of either coal men or railroad men for this theoretically beautiful system. Transportation was conserved by the tidewater pools in coal distribution in 1918 and to a lesser degree in 1920 and the same end has been sought and attained to some extent by the pools in effect at different times on the Lake front. By operating an open-top car pool during the period of government control of railroads there were certain objects gained during times of great stress. But then in those days nearly everything that could be pooled was thrown into the general pot by everyone to help the great cause of the war.

A proposal to pool the railroad equipment of the country is being pushed by the National Association of Owners of Railway Securities. The matter is now before the Interstate Commerce Commission for consideration and the railroads have submitted a report to that body that in general expresses opposition to the idea. It is pointed out by the roads that much that is claimed for the scheme is already being done by the present managements of the carriers and that it is only the restrictions that are placed on them both by law and through repressive public sentiment that prevents carrying the admirable features into fuller effectiveness. The railroad officials, although they do not say it in so many words, appear to have an old-fashioned idea that they know considerable about running the transportation machine, perhaps more than tinkerers from the outside. This is an idea that is common to most American business men with respect to their own particular activities.

Some of those who have noted the economies effected by pooling coal are persistent in advocating general pooling of coal, standardization into grades and distribution through governmental prescription. Pooling has its objections as well as merits and the objections on the part of coal and of railroads are much the same in general outline.

One common objection that must be given first place is in the fact that a large, expensive organization must be set up to administer the pools, an organization, as pointed out by the railroads, "duplicating many of the facilities and operations" now conducted by the present officials. No compensating saving has been shown in either instance. The free play of competition is hampered if not eliminated by such methods. Coal shippers find in the pools a loss of individuality and trade prestige, and buyers have complained that they have found in pooled coal the slate for which no one in particular could be held to blame.

The purpose and object—namely, elimination of waste—of those who favor pooling as a sort of panacea are beyond cavil. It behooves everyone to work with them toward this common end. Their formula of centralization must be modified before they can expect to get the fullest support, however. The war brought some experiences in how not to do things, as well as how to do some better. It were more profitable to seek the redevelopment of the right economic environment in which individual initiative may thrive and produce wholesome fruits than endlessly to encourage commission and centralized bureaucratic control of industry.

Who Wants Nationalization?

MORE than passing interest attaches to the development within the United Mine Workers of a division into left and right wings. The liberals or radicals, or whatever they may properly be termed, headed by John Brophy and guided by the Bureau of Industrial Research, constitute the left wing. They stand for a nationalization of the coal industry. On the other side are the conservatives, the old school, typified by such men as John L. Lewis, president of the international organization, and Frank Farrington, president of the Illinois miners.

At the Cleveland convention in 1919 the United Mine Workers adopted an out and out program of nationalization of the coal mines. They called on the federal government to acquire title to the mines and to operate them, giving the miners equal opportunity in the management. This demand and that for the 30-hour working week are interpreted as vague expressions of faith on the part of the workers that thus overdevelopment and the short work year could be corrected. At Indianapolis two years later, in the fall of 1921, they receded somewhat from their previous extreme position and created a Nationalization Research Committee, of which John Brophy was made chairman. Rock-bottomed sentiment was not so strong for nationalization and the conservative element in the miners' organization, gaining strength, withdrew a part of its support of the plan and let Brophy and his followers play with it.

And now, Brophy, having started his propaganda for nationalization of the mines, finds that even that measure of support is taken away. He is grieved to find that Mr. Lewis does not take his pet theories seriously and is undertaking to "smoke him out" on the question. Brophy has resigned from the nationalization committee and in an open letter to John L. Lewis demands that Mr. Lewis speed up the campaign for nationalization, and that Lewis assume the leadership in that which he several years ago asked the committee to undertake—the dissemination of propaganda among the members of the union and among the public. Mr. Brophy will carry the matter to the next convention, where he will test his radical strength with the conservative strength of the national officers.

The proposal for nationalization is nothing less than a plea for the elimination of the profit motive in industry, for the substitution of communistic control and management in place of private enterprise. Mr.

Brophy has had the effrontery to call it the American plan, whereas it is nothing but the Russian plan. The labor movement in this country has accomplished what it has and that has been much, by frankly recognizing the merits of individual enterprise, the "acquisitive instinct," as Mr. Robert Bruére indicts it in his book on the "Coming of Coal," and by organizing powerful unions to meet owners and managers in collective bargaining.

The urge for socialization or nationalization—they are one and the same—comes from abroad—it is an imported idea. In England labor has frankly declared war on private enterprise and seeks the nationalization of coal and transport—other things to follow, of course—and the practical conscription of capital. Brophy and the intellectuals who hold up his hands are following the lead from abroad.

Nationalization in any form would result in completely unionizing the coal fields, a condition sought by the organized workers. This end is held out as an added inducement for support and as a short cut to the solution of the big problem of the union in this country. It is certain to appeal strongly to those in central Pennsylvania who tried so hard last year to organize Somerset and Connellsville, and to those who lost New River and Kanawha.

In Continental Europe the tide of sentiment for nationalization of industry is reported to be waning. In Great Britain it is dangerously near the crest, with the Labor Party under control of clever socialists at the height of their power in Parliament. The movement, both as respects the railroads and the coal mines, is in its ascendancy here. As in England, there are in this country those outside the rail and coal industries who are most active in promoting nationalization. That is why the development of a left wing in the United Mine Workers and the pushing of active propaganda for nationalization of the mines is of more than passing moment. The professional radicals will continue to feed the discontent of mine workers.

Is Creosoted Timber a Menace?

OFFHAND judgments, made without experience or tests, have declared that creosoted mine timbers constitute a menace to the mines in which they are introduced. Reasonable enough is the idea that to soak a timber with oil, no matter how high is its flash point, is a sure way to make it a ready prey to flame.

However, this idea, like many others, does not appear to have any substantiation in actual practice. Some mine officials who have had such experience find that creosote helps to smother out the fire in a mine timber rather than to aid it. When a committee on treated fence posts made its report at the convention of the American Wood Preservers' Association at New Orleans, last January, it stated that experience on the Missouri, Kansas & Texas R.R. showed that creosoted yellow-pine fence posts were less subject to fire than posts that were untreated.

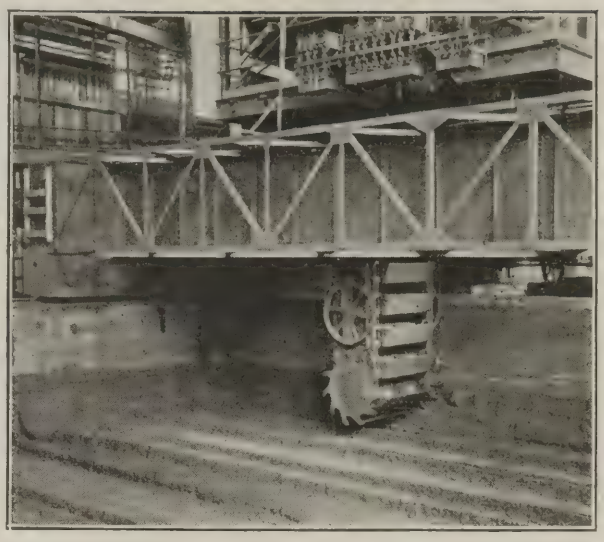
That railroad had 2,030,911 fence posts of which 1,651,333, or 81.3 per cent, were untreated and 378,578, or 18.7 per cent, were treated. In two years that railroad lost 5.795 untreated posts and only 76 treated posts. Thus 351 untreated posts in 10,000 were burned whereas only 2 in an equal number of treated posts were thus destroyed. The report adds that "a direct comparison of the relative fire-resisting qualities of treated and untreated posts cannot be made, as many of the untreated posts were partially decayed, making the wood readily susceptible to the flames." With this dictum one cannot feel in hearty agreement. Surely the fact that the timber which had been treated was not rotted and that which had not been treated was rotted did not militate against the fairness of the test. One reason why creosote is fire-resisting is that it greatly delays rotting. Of course, the comparison resulting from this experience is not between newly treated and untreated posts but between posts under normal conditions.

However, the chairman of the report may have known, as he is connected with the railroad, that the untreated posts had for the most part been longer in the ground than those which had been treated. The report fails to make a statement of any kind regarding this important element in determining the risk.

As counterbalancing the supposition that the treated posts were newer than the untreated must be cited the fact that the treated posts were of inflammable pine and the untreated posts were largely of less inflammable material.

The report goes on to say: "The fact that less than one hundred posts burned out of a total of more than 378,000 in service is evidence that they are not easily ignited and therefore are desirable in territories where there is danger of fire." This evidence should allay the fears of those who hesitate to put creosoted timber underground or to use it in surface construction.

The Market Softens



STOCKS of bituminous coal are increasing while production and prices drag. The end of the winter is in sight and householders are feeling easier. In the area where the lack of anthracite caused by the strike of five and a half months was most seriously felt, substitutes have saved the day and no one has gone cold. Within a month after the miners returned to work production of soft coal was in excess of consumption and that of hard coal climbed to its highest level and has been maintained there.

A survey of the stocks of coal in the hands of consumers and retail coal dealers just completed for Federal Fuel Distributor Wadleigh discloses that on Jan. 1 there were 36,000,000 tons of soft coal in reserve piles, a gain since Sept. 1 of 14,000,000 tons. Around 10,000,000 tons appears to have gone into reserves in September and October and 4,000,000 tons in the last two months of 1922. Statements that the coal crisis is passed are not correctly based on the assertion that production is now in excess of consumption, for that was less true at the end of the year than in the fall. They are true because the level of stocks has been raised sufficiently to relieve anxiety. It has been demonstrated time and again that when reserves approach four weeks' requirements demand falls to match consumption and prices settle at a low level.

The figures released by the Fuel Distributor indicate that by Feb. 1 reserves were approaching four weeks' average requirements. Consumption of bituminous coal around 39,000,000 tons in October, steadily increased through the winter and now probably is around 43,000,000 tons per month, or about 9,800,000 tons per week, exclusive of exports. As an indication of where the coal is going it may be noted the production of pig iron gained 600,000 gross tons from October to January, or 40 per cent.

Rosedale Uses Bumping Tables to Wash Its Product, Mixing It for Coking Purposes with Gas Coal

By George Atwell Richardson*
Philadelphia, Pa.

Cambria Steel Co's Washing Plant Cleans Coal with Bradford Breakers and Riffled Tables—Coal Is Dried in Big Draining Pits for Four Days, After Which It Is Excavated by Reclaiming Bridges

THE Rosedale coal-washing plant of the Cambria Steel Co., at Johnstown, Pa., forms an integral part of a group comprising: (1) The Rolling Mill and Rosedale mines, from which the coal is hauled and hoisted direct into the coal-washer building; (2) the coal washery and subsidiary buildings where the coal is washed and then mixed with coal from other mines to form the proper coking mixture; (3) the byproduct plant where the mixed coals are converted into coke for use in the manufacturing plants and into byproducts for outside consumption.

The coal washery is of interest because it is the largest and most modern of its type in the country. Construction of the development of which it forms a part was started in 1917 and completed in the spring of 1922.

*Midvale Steel & Ordnance Co. and Cambria Steel Co.

Note—This article deals with coal-washing equipment recently installed at the Rosedale byproduct plant of the Cambria Steel Co., at Johnstown, Pa. The present article is the third in a series of four describing an unusually interesting combination of modern mining methods and byproduct-plant practice. The first two, entitled "Cambria Steel Co. Drops Coal Down Well, Loads It at Bottom and Hauls It to Ovens" and "Haulage, Hoisting and Dumping Practices at Rosedale Mines," appeared in the issues of *Coal Age* for Aug. 31 and Sept. 22, 1922, respectively.

Note—The headpiece shows the leg of the "digger crane" removing washed coal from a drainage pit. The bins are ten in number and each holds 1,500 long tons.

In previous articles the modern methods of mining, hauling and handling the coal were taken up in detail, ending with a description of the 175-ft. steel headframe from the top of which the coal is dumped automatically into storage bins at the top of the coal-washer building.

The movement of the coal in the coal washery is in one general direction from the incoming to the other end. At this point is located a subsidiary building, or addition, which houses coal-mixing and handling equipment, which will be described in detail later. Gas coal must be mixed with the local coal to obtain a proper coking material, and this is brought in by rail from mines at a considerable distance. The total distance from the incoming end of the coal-washer building to the track hopper where gas coal is unloaded is 841 ft., the washer building itself being approximately 564 ft. long by 100 ft. wide. Concrete is used for all foundation work, and the superstructure is of brick and steel.

As has already been mentioned, the coal from the local mines is hoisted and dumped into storage bins having a capacity of 1,000 gross tons of coal. From the storage bins the coal passes down into two 12x17-ft. Bradford breakers. In the original plans it was provided that the coal should pass through crushers, and

FIG. 1—INCLINED CONVEYOR LOOKING DOWN SLOPE

This 30-in. belt brings the coal from the Bradford breakers to the top of the washery and delivers it at that point to a horizontal belt, which carries it to the bins over the washers.

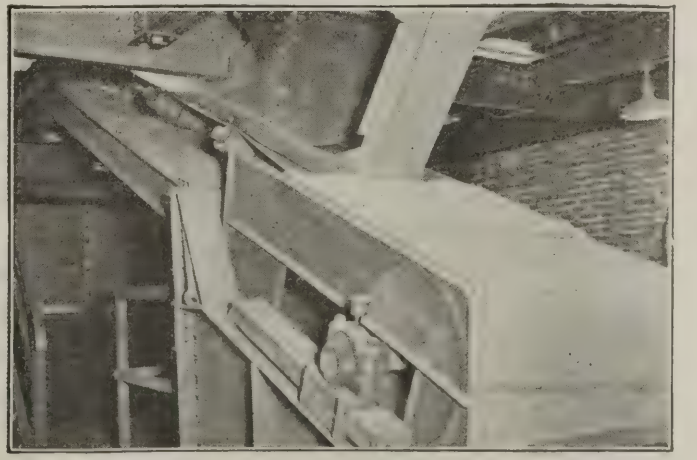


FIG. 2—JUNCTION BETWEEN CONVEYORS NOS. 1 AND 2

Coal to be washed drops onto a 30-in. inclined conveyor belt known as No. 1 and is taken up to the top of the washery, where it is dumped on a conveyor belt known as No. 2.

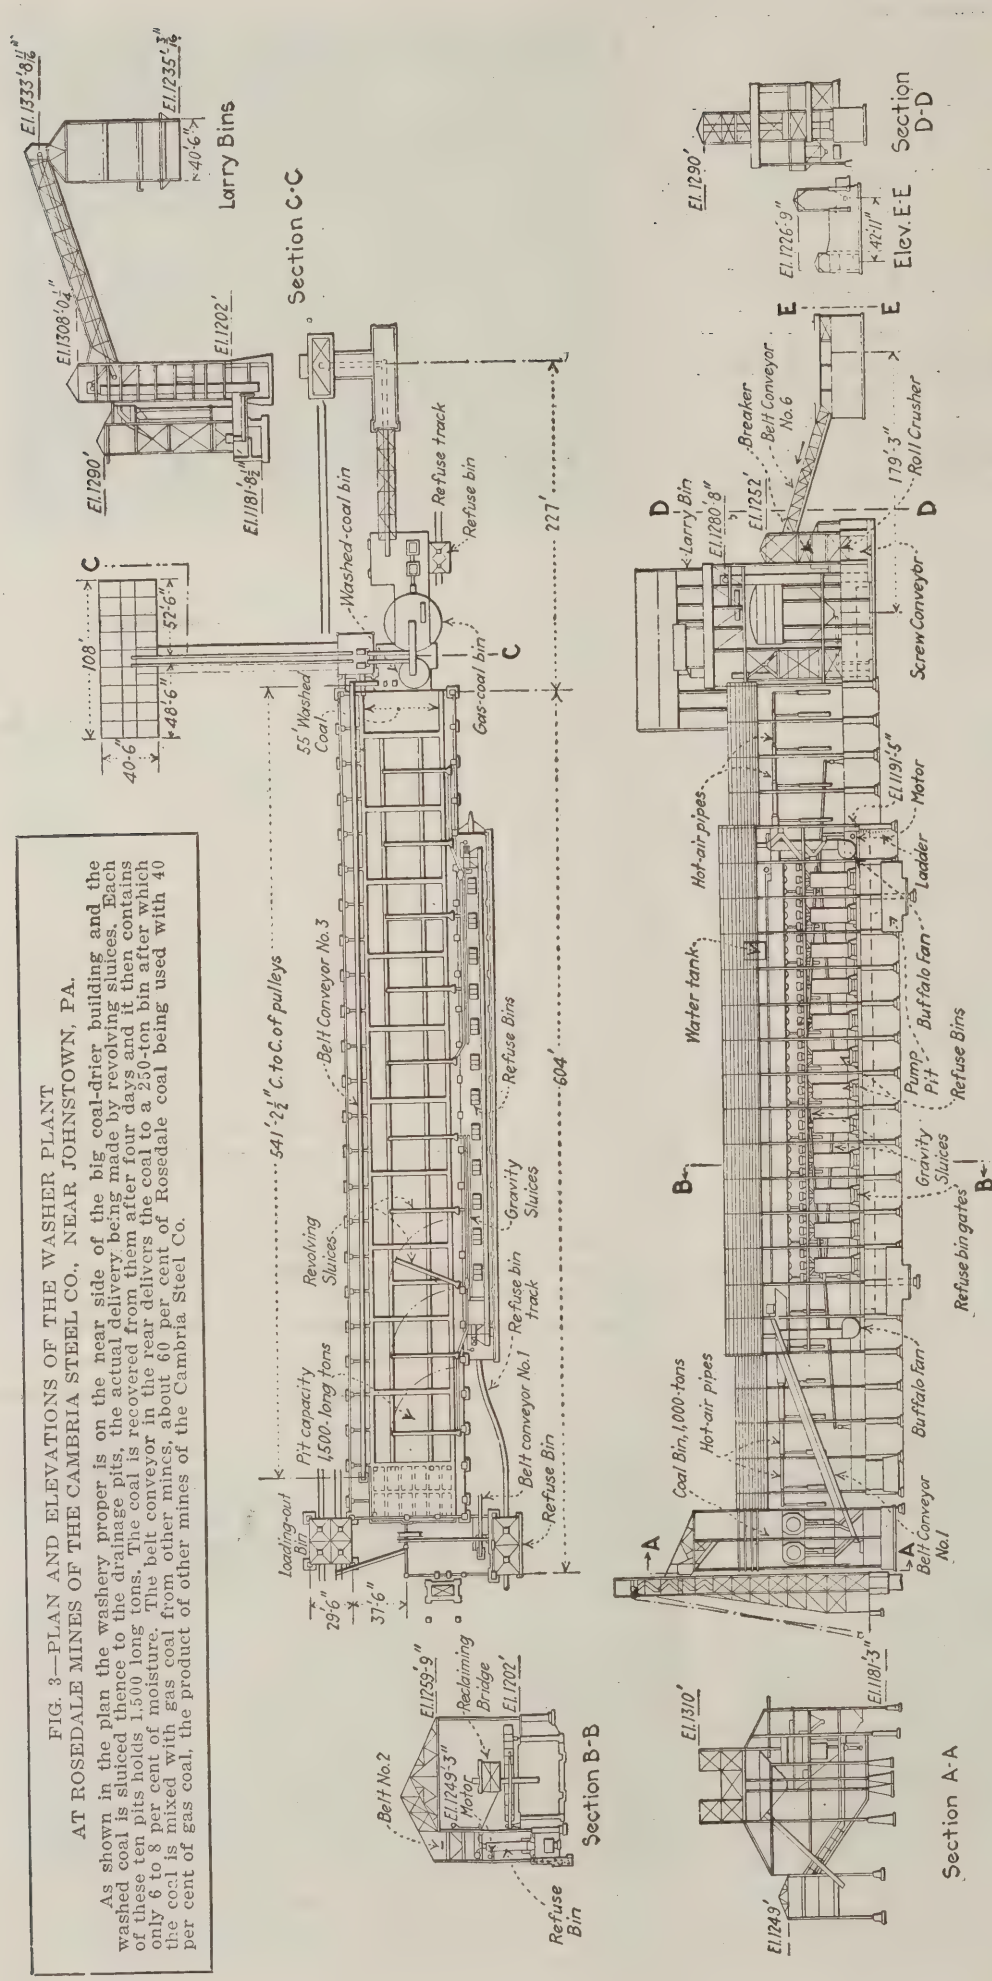

FIG. 3—PLAN AND ELEVATIONS OF THE WASHER PLANT AT ROSEDALE MINES OF THE CAMBRIA STEEL CO., NEAR JOHNSTOWN, PA.

As shown in the plan the washery proper is on the near side of the big coal-drier building and the washed coal is sluiced thence to the drainage pits, the actual delivery being made by revolving sluices. Each of these ten pits holds 1,500 long tons. The coal is recovered from them after four days and it then contains only 6 to 8 per cent of moisture. The belt conveyor in the rear delivers the coal to a 250-ton bin after which the coal is mixed with gas coal from other mines, about 60 per cent of Rosedale coal being used with 40 per cent of gas coal, the product of other mines of the Cambria Steel Co.

space has been left for these.

Part of the crushed coal was to be used in the boiler house, and all of the finer material was to go to the washer tables. The Rosedale coal, as it is mined at present, breaks readily, however, and no crushers are required. In fact all of it breaks up so fine without crushing that it is suitable for the washer tables, and as a result the present practice is to use one of the breakers for supplying boiler fuel, the other supplying all the coal the washery needs.

Coal for the boiler house and similar uses passes down from the breaker onto a flight conveyor which carries it up into a 250-ton loading-out bin. Coal also can be carried direct from the storage bins to the loading track by a gravity chute. (See Fig. 5.)

The coal that is to be washed drops onto a 30-in. inclined conveyor belt known as No. 1, and is taken up to the top of the washery, where it is dumped on conveyor belt No. 2. This second belt passes over the bins that supply the coal to the washer tables, the coal being deposited uniformly at any desired point by an automatic tripper. (See Figs. 1, 2 and 8.)

The product of the Rolling Mill and Rosedale mines contains large quantities of foreign matter, and after breaking it up, in which operation there is a cobble loss of 1 per cent, the coal is washed to eliminate as much refuse as possible. This entails a further loss of about 9 per cent, the ash and sulphur contents being reduced materially.

The thoroughness of the washing is checked constantly by means of analyses of the coal supplied to the washing tables and also of the coal and refuse which the washing tables deliver. Samples are taken, mixed, quartered and dried, results being tabulated as shown in the following table abstracted from the daily operating records of the plant. All figures shown are based on analyses made of material dried at 105 deg. C.

FIG. 4—SIDE VIEW OF CAMPBELL BUMPING TABLES
In this view can be seen indications of the seventy-two bumping tables and chutes. A cam which pushes the table forward and the springs which return it, as also the bumping block which suddenly brings that return motion up with a jerk, can be clearly seen, all being to the right of the line of tables.

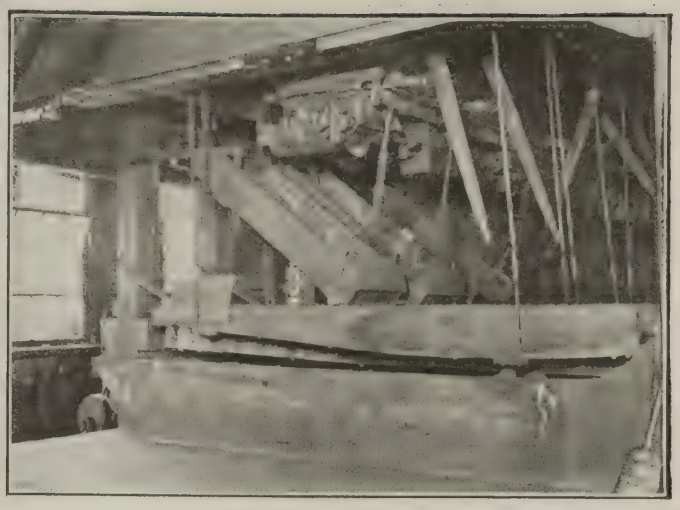

FIG. 6—QUARTERING VIEW OF TABLE FROM FRONT
The worm feed above the tables regulates the supply of coal to the chutes. In practice all the bevel gears are covered up by a sheet-iron box. The gates in the bottom of the raw-coal hoppers are opened and closed by hand levers which are never used to adjust the feed.

These analyses, of course, will vary from day to day but the figures given afford a good idea of the conditions that are encountered.

That part of the coal washery given over to the actual washing equipment consists of a series of galleries on which the various pieces, parts and controls are located, the materials being handled by gravity as far as possible.

The top gallery is little more than a runway paralleling No. 2 conveyor and extending across the top of the coal bins. This gives convenient access to the automatic tripping equipment and to the incline which follows down alongside No. 1 conveyor. At each end of this gallery are water tanks into which the washing water is pumped. Adjacent to each tank is a 50-hp. induction motor, these motors being used to operate the No. 1 and No. 2 conveyors.

Washing water is used over and over again as far as possible, fresh water being added only in quantities sufficient to replace losses. The water drains down into sumps located on the basement level and from that point is pumped back to the tanks. For this purpose 100-hp. continuous-duty induction motors are used, these being direct connected to two-stage centrifugal pumps designed to operate against a head of 115 ft. (Fig. 10.)

Seventy-two Campbell washing tables are used to clean the coal, these being capable of handling 4,000 gross tons of coal per 10-hr. day. These tables are

FIG. 5

Washery and Headframe

On the right in the foreground is the headframe of the shaft; on the left in the rearground is the washery. In the center is the 250-ton bin with the shed over the flight conveyor by which that bin is supplied. This bin is used for loading railroad cars with coal for use in the boiler house and for other purposes. A large storage 1,000-ton bin is ranged alongside the headframe for direct loading by the shaft skips, and if desired, coal can be run direct from that bin to the railroad cars, the gravity chute in the foreground being used for that purpose.

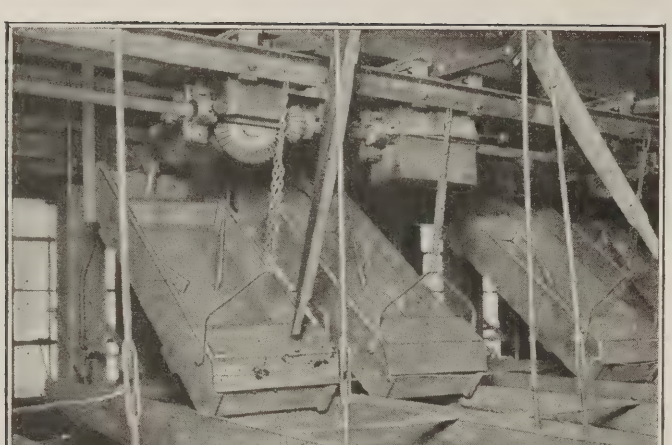

FIG. 7—FRONT VIEW OF BUMPING WASHING TABLES

Seventy-two of these tables clean the coal, their aggregate capacity being 4,000 gross tons per 10-hr. day. Each table is suspended by two stirrups. They are pushed forward to the limit of their travel by the action of cams. Aided by springs they are brought back with a sharp jolt against the bumper post in the rear. The tables are corrugated, and the coal is readily sluiced over the corrugations, but the refuse stays in the miniature traps till the sharp jolt causes it to slide backward. Repeated jolts bring it to the rear of the table and to the refuse chutes.

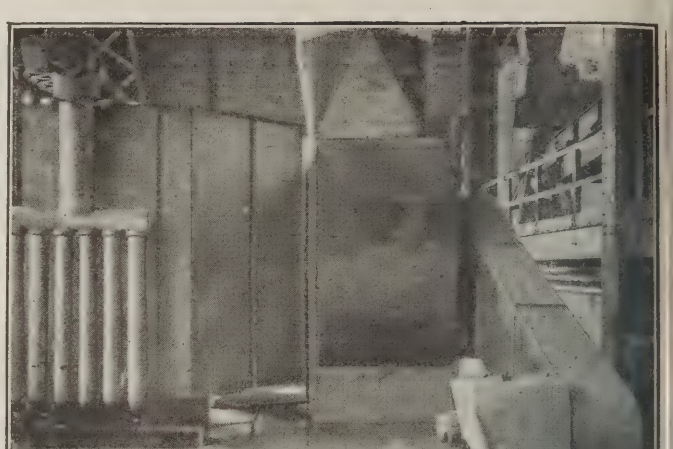

FIG. 9—MOTOR-DRIVEN FAN AND HEATING EQUIPMENT

Two units like this, one at either end of the gallery behind the refuse bins, provide the hot air by which the building is warmed in cold weather. One difficulty in drying slack by the slow process of drainage is that in winter it may freeze rather then drain. For this reason the house where the slack is dried must be kept warm during the winter season. The piping system is outlined in part in Fig. 3 and can be seen also in Figs. 17 and 19. The pipes travel near the roof of the drier shed with branches at short intervals descending toward the floor.

operated in units or batteries of twelve each. On a gallery immediately below the washing-table floor or gallery are six 15-hp. induction motors, each motor operating one unit. From the motors silent chain drives connect with the cam shafts on the washing floor, the cams themselves being used to cause the bumping action which is the essential part of the washing operation.

COAL ANALYSES OF COAL WASHED AT ROSEDALE PLANT, PER CENT

	Before Washing			Washed Coal			Refuse		
	Volatile	Ash	Sulphur	Volatile	Ash	Sulphur	Volatile	Ash	Sulphur
1.....	16.41	10.23	2.98	16.56	7.33	1.40	16.03	61.04	24.85
2.....	16.50	10.26	3.02	16.60	6.84	1.37	15.95	59.75	24.45
3.....	16.61	11.32	2.60	16.68	7.88	1.29	15.46	62.84	21.92
4.....	16.59	11.97	2.12	16.62	8.43	1.21	15.85	64.28	18.68
5.....	17.07	12.51	2.11	17.15	8.76	1.12	16.40	61.28	15.13

A chain drive operating from the camshaft in series with a second turns a line shaft hung in front of and under the coal hoppers. On this line shaft are bevel gears which turn the worms in feed cylinders at the bottom of each hopper. Each battery or unit has its own independent drive. Gates in the bottom of the hoppers are opened and closed by hand levers. These are never used for adjusting the feed. (See Figs. 4, 6 and 7 for details; also a cross-section of a typical unit, Fig. 13.)

When the equipment is operating, coal from the hoppers passes through the worm feed and drops onto the feed chute, which is suspended at an angle of about 40 deg. In this chute, by means of a dam and suitable baffles water from the tanks above is intimately mixed with the coal, and this mixture in turn spills over and down onto the washing table proper.

The general arrangement of the washing tables and equipment is clearly indicated in the diagram. The individual tables are suspended on two rockers, or stirrups, the front one being adjustable for height by a hand lever. In this way the operating position of the table can be varied to meet conditions. The exact angle depends on the character of the coal being washed. Ordinarily it will be determined by the appearance of the table, the coal having a tendency to pile up if the proper angle is not being used. On the other hand, the analyses may show that the refuse is too high.

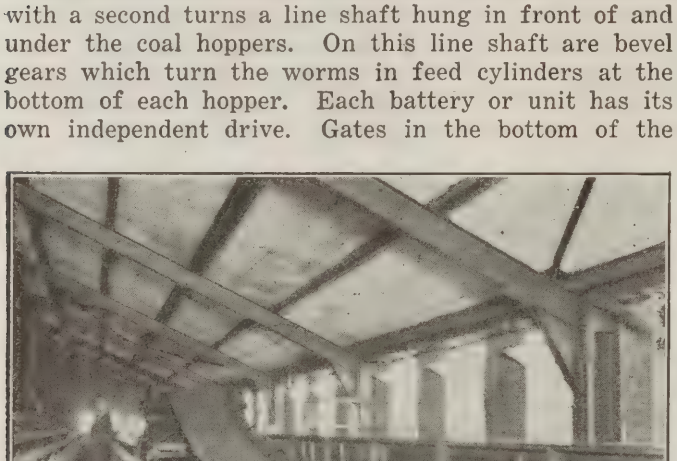

FIG. 8—AUTOMATIC TRIPPER OVER WASHER-TABLE BINS

The tripper can be moved to any point over the row of bins, where, by deflecting the belt, the load is discharged into the bin desired. This system used for many years for the handling of coal to the bunkers over boilers and by metal mills for the bedding of ores is well suited for distributing coal to a row of washer tables.

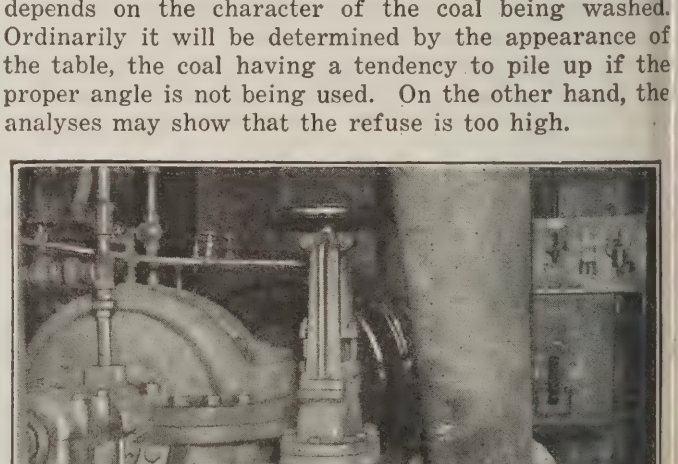

FIG. 10—CENTRIFUGAL PUMPS RESTORE WASH WATER

Wash water drains down the sumps, at each of which is a pump like that shown, which delivers the water back to tanks near the roof of the building. The pumps are driven by 100-hp. continuous-duty induction motors to which they are direct connected. The pumps have two stages and are designed to operate against 115-ft. head.

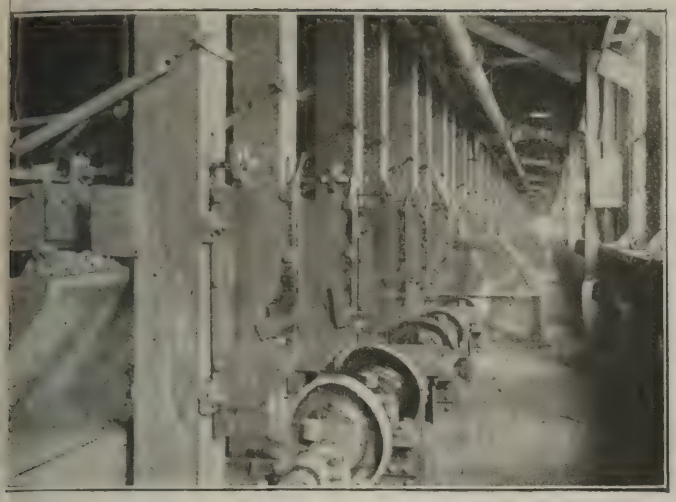

FIG. 11—CAMS BY WHICH WASH TABLES ARE OPERATED
Six 15-hp. induction motors, each driving a battery of twelve units, are placed in a gallery below the wash tables. and through a silent chain drive revolve the cams by which the washery tables, in turn, are actuated. As will be noted, these cams are placed near the level of the washery floor.

FIG. 12—REFUSE BINS REST ON CONCRETE PIERS
The waste chutes and refuse bins are of wood, as the waste has a high sulphur content. Consequently only a non-corrodible material could be used in their construction without frequent replacement. The bins taper gently from top to bottom, losing 6 in. of width in the 28 ft. of their depth.

In the bottom of the tables are corrugations, or riffles, in which the refuse is caught and gradually worked back. At the back end of the tables rods project and connect with rocker arms by means of a slotted joint, these rocker arms being actuated by the cams, which can be seen clearly in the illustrations.

The actual washing of the coal is accomplished by a combined rocking and jolting action. As the cams rotate the tables are pushed forward to the limit of their travel, and then, aided by the springs, are brought back sharply with a jolt against the bumper posts at the back. The refuse, being heavier than the coal, tends to settle in the riffles and gradually works back while the light coal is slopped over with the water into the

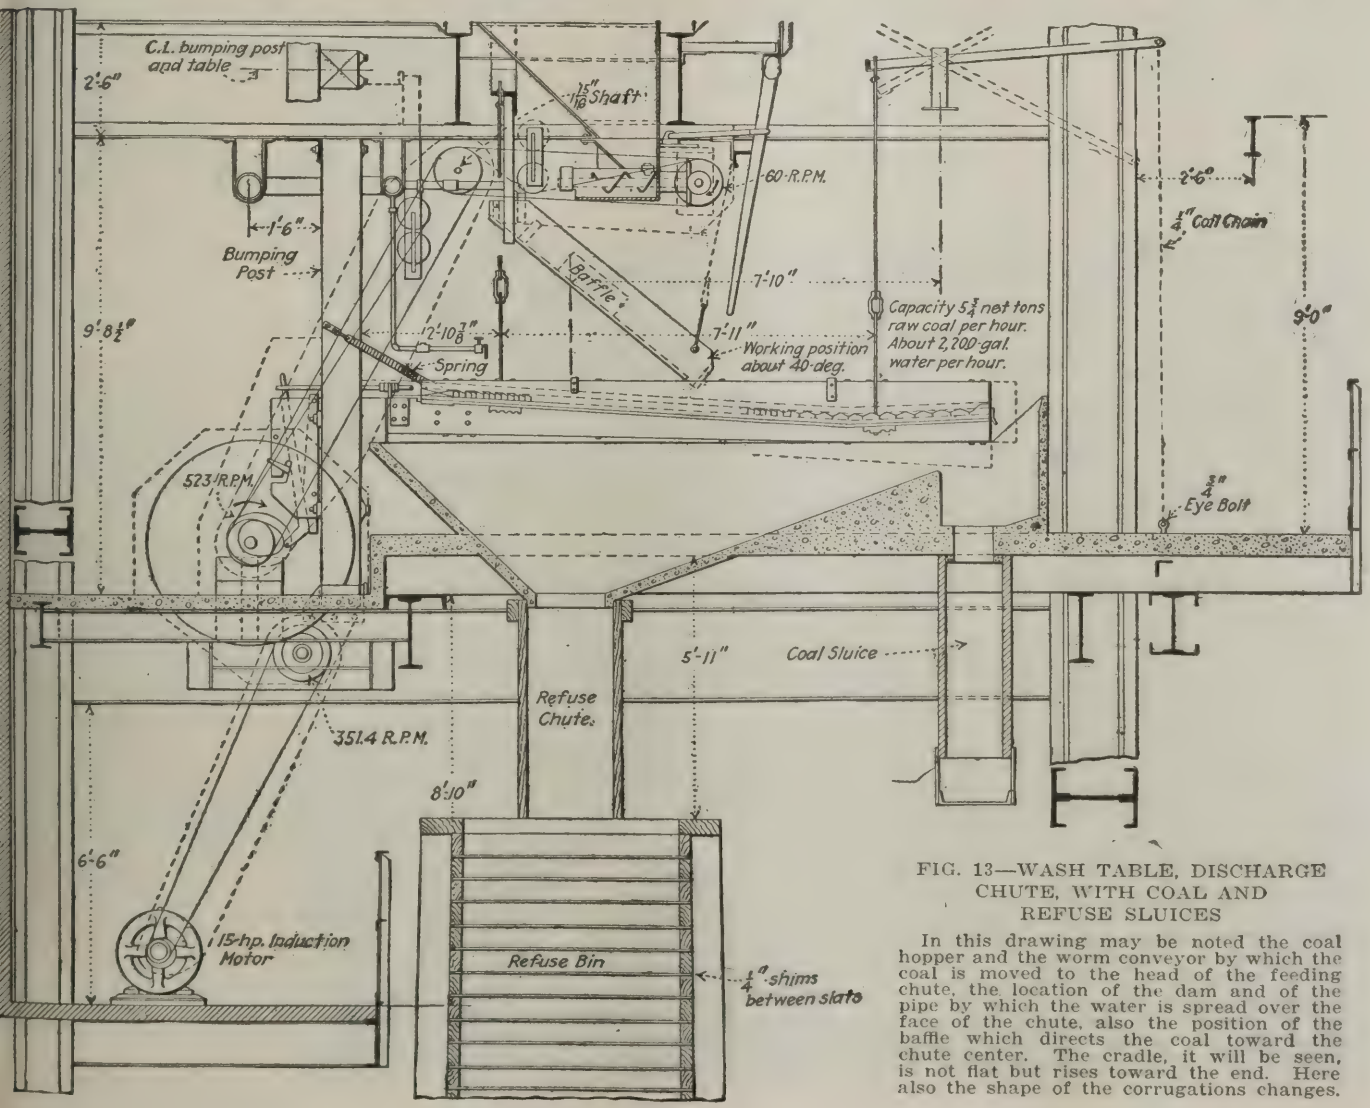

FIG. 13—WASH TABLE, DISCHARGE CHUTE, WITH COAL AND REFUSE SLUICES
In this drawing may be noted the coal hopper and the worm conveyor by which the coal is moved to the head of the feeding chute, the location of the dam and of the pipe by which the water is spread over the face of the chute, also the position of the baffle which directs the coal toward the chute center. The cradle, it will be seen, is not flat but rises toward the end. Here also the shape of the corrugations changes.

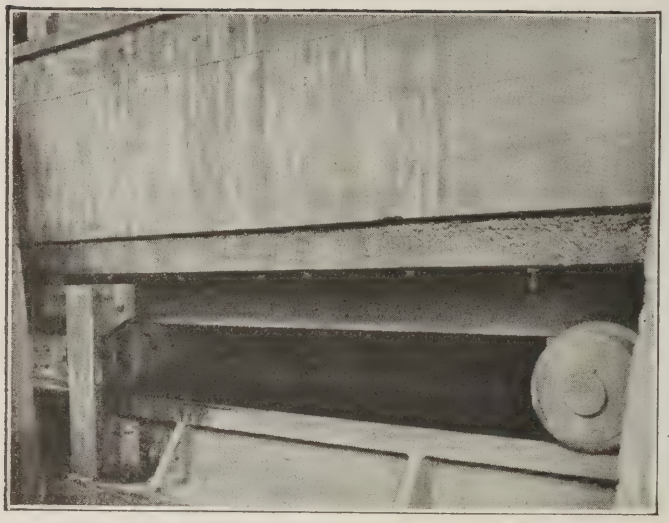

FIG. 14—GATE CLOSING BOTTOM OF REFUSE BIN
Mechanically operated horizontal gates mounted on wheels close the gates of the refuse bins, being propelled by a motor-driven rack-and-pinion movement. The refuse is dumped into railroad hopper cars as shown in Fig. 21.

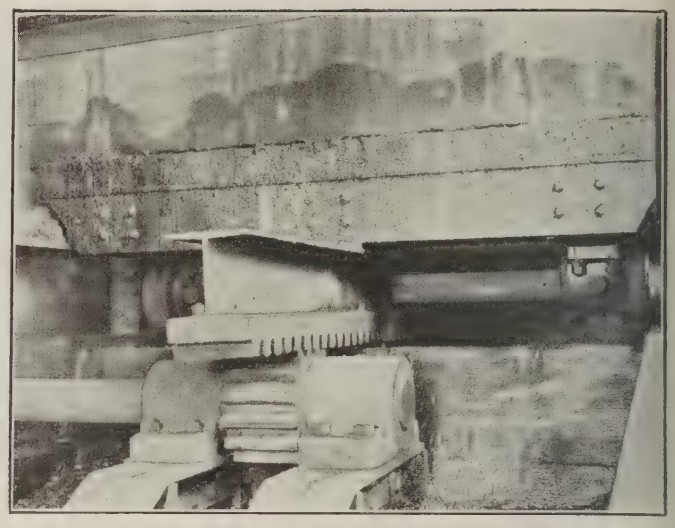

FIG. 16—ANOTHER VIEW OF GATE OF REFUSE BIN
This shows the pinion and the long girder on the underside of which is a rack. Through this girder pass the axles of the wheels by which the gates are supported and on which they roll forward or backward.

coal sluices. On the way back the refuse meets a second stream or spray of water which aids in removing any coal that may remain. After this the refuse drops down into the refuse chutes.

Sulphur forms a large percentage of the refuse, as shown by the analyses given above. For this reason it is necessary to construct the refuse chutes of wood if a reasonable length of life is to be insured. There are thirty-six refuse chutes in all, or one chute for every two tables. These dump in turn into wooden refuse bins which are tapered from top to bottom, there being a total of twelve bins, or one for every six tables.

The refuse bins rest on concrete piers which project above the floor level of a gallery which is below the level of the floor surrounding the drainage pits on the other side of the building (Fig. 12). These piers provide the necessary clearance for the insertion of mechanically operated gates which close the bottoms of the refuse bins. The gates are horizontal and mounted on wheels so that they can be moved back and forth on a short track by means of a motor-driven rack-and-pinion movement (Figs. 14 and 16). Individual safety switches and motors are provided for each gate.

At each end of this same gallery are located the heaters by which the building is warmed during cold weather. Motor-driven fans circulate the hot air to various parts of the building, as shown in the longitudinal elevation. (Fig. 3.)

The refuse is dumped into hopper cars which are run into the washer building on the lower ground level.

FIG. 15

Drainage Shed

Illustration is from a photo taken of the drainage pits before the belt was installed or the pits used. Note the sluices by which the coal from the washery is directed into the pits, of which there are ten. The coal remains in them at least four days before it is removed by the reclaiming bridges. It has then lost so much water through the cracks between the boards at the bottom that only 6 or 8 per cent of water remains. The pits are filled with coal to the level of the tops of the walls and each holds when filled 1,500 gross tons.

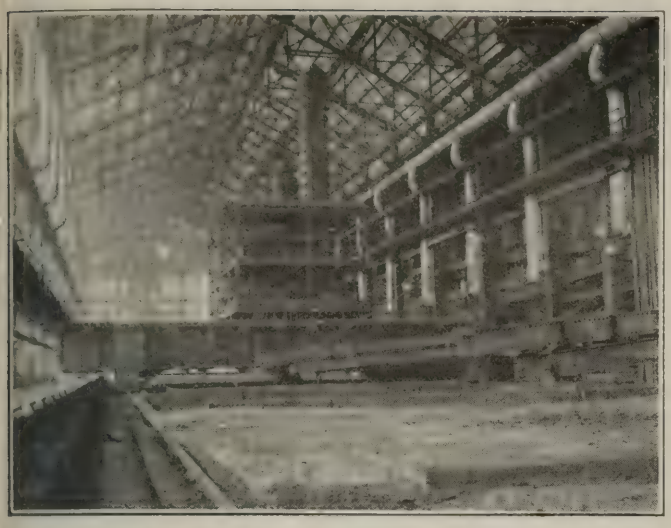

FIG. 17—DRAINAGE SHED WITH TWO DIGGER CRANES

In front of the reclaiming bridges with their buckets lifted clear of the drainage pits are three separate sluiceways from which the coal is discharged when the pits in the foreground are being filled. Note the belt on the left, which receives the dried coal from the digger cranes and carries it to the mixing plant.

FIG. 19—VIEW OF SHED WITH FORE PITS FILLED

The Cambria Steel Co. always has exhibited a preference for drainage as against mechanical methods of ridding the coal of its moisture, a similar system of draining having been installed many years ago at its Franklin plant. It is slow but effective and economical.

This is the lowest gallery. The coal-washer building is on the side of a hill so that the ground levels on the two sides are quite different, the washers being on the downhill side. (See section BB, Fig. 3.)

Halfway up the side of this gallery (Fig. 21) is the trimmers' platform and at each end are the rooms which house the motors and pumps by which the washing water is circulated. The refuse, which is loaded into the cars, is hauled to the dumps, for it has no commercial value. The disposal of the refuse is of interest but the most important part of our discussion has to do with the handling and disposal of the coal, and its path will now be followed to the coke ovens.

The coal and water from the washer tables pass down through gravity sluices into the drainage pits. There are ten of these, each having a capacity of 1,500 gross tons. They are so designed that the coal recovered from them contains only from 6 to 8 per cent moisture. (Fig. 15.) The sluiceways are so arranged that the flow of water and coal can be diverted to any pit and to any part of the pit so as to fill it uniformly to a level with the top. Ordinarily four days should be ample for draining off the water, which would be the usual period with all ovens operating at capacity. This period will be greatly exceeded when plant demands are not heavy.

The drainage pits are served by two reclaiming bridges, or, as they are locally known, "digger cranes," which are equipped with continuous bucket diggers which deliver the washed coal to a 36-in. conveyor belt (No. 3) running the entire length of the building (Figs. 15, 17, 19 and headpiece). This belt in turn delivers the coal to the mixing plant.

Rosedale coal is low in volatile constituents and must be mixed with high-volatile coal in order to obtain a mixture suitable for coking. Coal of this character is brought in from other mines of the company and is not washed at this place.

The Rosedale coal is carried from No. 3 conveyor by

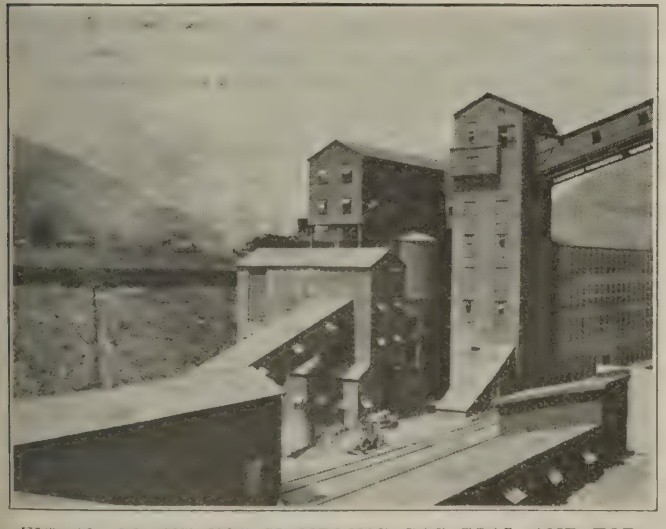

FIG. 18—PLANT FOR HANDLING GAS COAL AND FOR MIXING LATTER WITH LOCAL PRODUCT

Hopper cars are discharged in the shed to the left. The coal is elevated by a belt conveyor in the crusher shed to the right of that building. The next structure to the right houses the elevator equipment, and to the side at a lower level may be seen the gas-coal storage bin. Under this bin are the coal mixers. The building still further to the right covers the elevators by which the mixed coal is hoisted and dumped onto the conveyor operating in the gantry to the extreme right. This conveys the coal to the bunkers at the ovens.

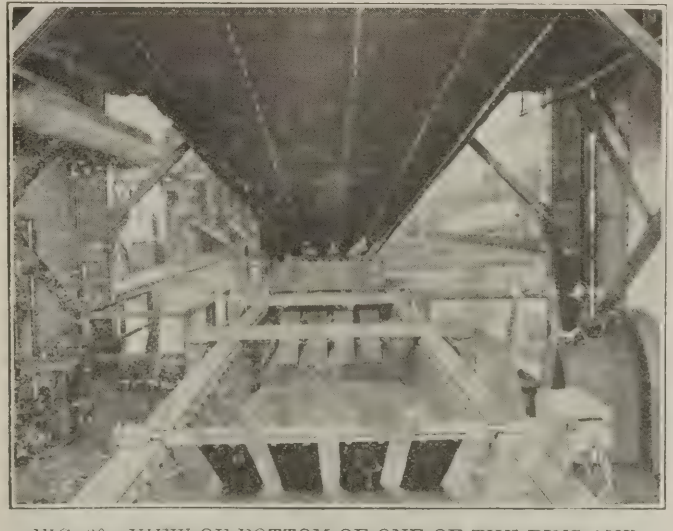

FIG. 20—VIEW OF BOTTOM OF ONE OF THE BINS AND BELTS OF PROPORTIONING FEEDERS

The fingers shown on the belt are part of the apparatus which controls the character of the mixture. When the coal feeds improperly the fingers drop and establish electrical contacts which stop the equipment immediately. The washed-coal bin, the hopper bottom of which can be seen in the illustration, has a capacity of 250 gross tons and the gas-coal bin of 1,250 gross tons. A view of the tops of the drier pits can be seen in the rear. This will give a suggestion as to location in the building of the proportioning feeders.

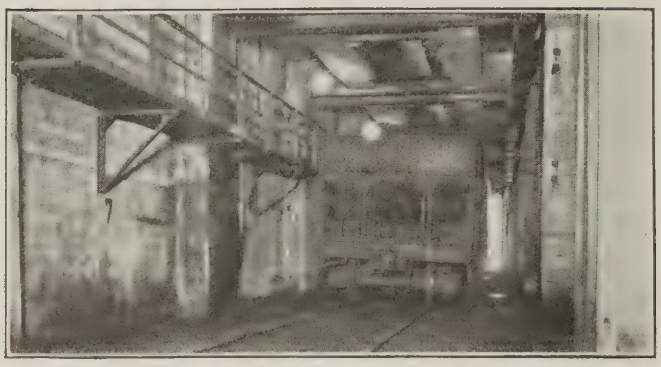

FIG. 21—HOPPER CAR PASSING UNDER WASTE BIN
Note the trimmers' platform on the left. The gallery is on the lower side of the washery and is the lowest part of the structure, which is built on a side hill.

a second conveyor and bucket elevators to the washed-coal bin. This cannot properly be called a storage bin as storage capacity is not required and the quantity that it will hold is less than 250 gross tons.

The high-volatile, or gas, coal comes in at the east end of the plant and is dumped directly into a railroad hopper and onto reciprocating gates which feed the coal uniformly onto a conveyor belt (Fig. 18). From this point the coal is elevated in two stages to roll crushers. Before entering these it passes through a Bradford breaker. From the crushers the coal is carried to a bucket elevator by a screw conveyor and lifted into the gas-coal storage bin which has a capacity of 1,250 gross tons. The crushing reduces the gas coal to a size uniform with that of the washed coal. This is necessary, as otherwise the coals would separate in handling, and it would be impossible to maintain a uniform coking mixture.

From the bins the gas and low-volatile coals feed by gravity onto proportioning feeders. These are nothing more than two short belt conveyors moving toward each other and dumping the coal at the middle (Figs. 20 and 22). The supply to each conveyor can be so regulated that any desired mixture can be obtained, ranging in high-volatile coal from as low as 20 per cent to 80 per cent. Under normal operating conditions the usual mixture is about 40 per cent high-volatile and 60 per cent low-volatile. The quantity depends, of course, upon the analysis of the coal.

Automatic stops are provided on the proportioning feeders so that the apparatus is brought to a stop if the coal is not being fed properly. The fingered gates shown in the illustration drop down when the supply diminishes, and in so doing establish the necessary electrical contacts to operate the controls.

A paddling, or pug-mill, arrangement receives the coal from the proportioning feeders and plays its part in forming what is finally an unusually thorough mixture of the two grades of coal.

Two spiral screw feeders which receive the coal from the pug mill serve the double purpose of aiding in thoroughly mixing the coals and delivering them to two bucket elevators and thence to two conveyor belts which deliver the coal into a 3,000-ton coal bunker above the coke ovens (Fig. 23). In practice only one of these screw feeders is used, the other being held in reserve.

The electrical installations form an interesting feature of the coal washery. More than 350 motors are located in the washer and byproduct plants and fully 10 per cent of this number are located within the limits of the washer plant. Equipment of the most modern type has been installed. This includes inclosed safety switches and emergency switches for shutting down equipment from any point in the plant. High-tension current is brought to a rotary transformer station and stepped down to 220 volts. From these facts it will be seen that the Rosedale coal washer plant forms a most interesting example of modern coal-washing practice.

FIG. 22—END VIEW OF MIXING EQUIPMENT
The gas coal is crushed to the same size as the washed low-volatile coal so that when mixed they will not tend to segregate by sizes. Both coals are dropped into separate bins and then fed by gravity onto proportioning feeders, which are two short belts moving toward each other and dumping coal in the middle.

FIG. 23—CONVEYOR BELTWAY TO COKE OVEN
The coal being washed, 60 per cent of it is mixed with 40 per cent of gas coal. That, at least, is the usual mixture. It then goes to the ovens by the beltway, or bridge, shown.

ON DEC. 1 THERE WERE IN EFFECT, under the terms of the general leasing laws, 362 coal-prospecting permits, licenses and leases covering 281,818 acres of Government lands in certain western states, according to the U. S. Bureau of Mines. There were in operation on these lands 77 mines, which had reported to date a production of 833,000 tons of coal. Of a total of 313 coal-prospecting permits issued, the largest number, 78, was in Wyoming, 62 permits had been issued in Colorado, 43 in Montana, 29 in Utah, 26 in Oregon, 22 in Nevada and 20 in Washington. Of 44 leases for the production of coal, Utah, with 15 leases, led; Wyoming, with 8 leases, was second; Colorado, with 7, was third. The total minimum annual production of coal required under the leases granted amounts to 1,559,525 tons. It is estimated that there are 311,905,000 tons of coal in lands so far leased. The growth of coal production on leased public lands is shown in the following tabulation of output: 1920, 117,619 tons; 1921, 322,596 tons; 1922 (eleven months), 388,330 tons.

Municipal Water-Purification Plant Erected and Operated by an Illinois Coal Company

Plant Designed to Purify Half Million Gallons Daily—Will Store Enough Water to Afford Twelve Days' Supply at That Rate—Soda-Alum Solution Throws Down Solids—Chlorine Destroys Germs

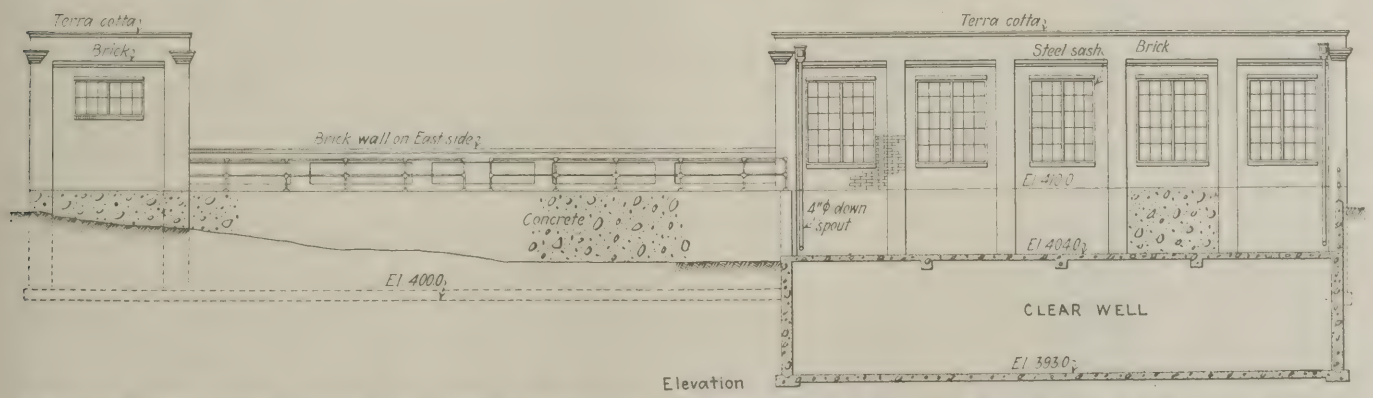
By Frank H. Kneeland*
New York City

MANY modern coal-mine villages differ in little or nothing, so far as living conditions and domestic conveniences are concerned, from communities of equal size and population located outside the mining regions. There was a time, well within the memory of men now living, when almost "any old shack" was considered good enough for a coal miner and his family to live in. Even within the past two decades the most popular dwelling that mining companies could erect in certain localities was a three-room cottage. In such places larger, more convenient and more pretentious dwellings went untenanted so long as any of the smaller houses were available.

Miners Looking for Improved Surroundings

Much of this is now changed. For almost ten years this country has been cut off from the influx of foreign labor which formerly sought our shores. This lapse of time has done much to Americanize the foreign population of isolated communities. This transition doubtless has been stimulated in no small measure by such other unheralded though powerful agencies as the "movies" and more recently "radio." The result is that the miner of today demands conveniences in his home and surroundings of which his predecessors of a generation ago never dreamed. The American standard of living has gained a firm hold upon him.

In any community, regardless of its size or character, sanitation is the first requisite to public health, and the provision of an adequate supply of potable water is the first and most important step in any scheme of municipal sanitation.



Years ago the town of Zeigler, Ill., was owned by a coal company. Today it is an incorporated city, with a city government entirely independent of the coal firm that made its existence possible. It is, nevertheless, a "one-industry town" in perhaps the strictest sense of the word. Inasmuch as it is highly important that the Bell & Zoller Mining Co., the mine owner, should have in its employ men that are in a strictly healthy condition, this firm has undertaken to supply the town with suitable water for both house use and fire protection.

To this end, a water-treatment and filtration plant of more than a half million gallons daily capacity is being built by this company near its No. 1 mine. The filter equipment for this plant is manufactured by the Roberts Filter Manufacturing Co., of Darby, Pa., and the plant is being installed by the Baumes-McDevitt Machinery Co., of St. Louis. The plant is constructed of concrete, reinforced concrete, brick, steel, glass and similar permanent and fireproof materials.

Water from the Big Muddy River is pumped to a 6,000,000-gallon storage reservoir adjacent to the plant. Thence it gravitates to the automatically controlled chemical mixing plant, where it is mixed with a soda-and-alum solution, the quantity of which is determined by the rate at which the water enters the plant. A series of baffles in the chemical tanks insures a thorough and intimate mixture of the raw water with the treating solution.

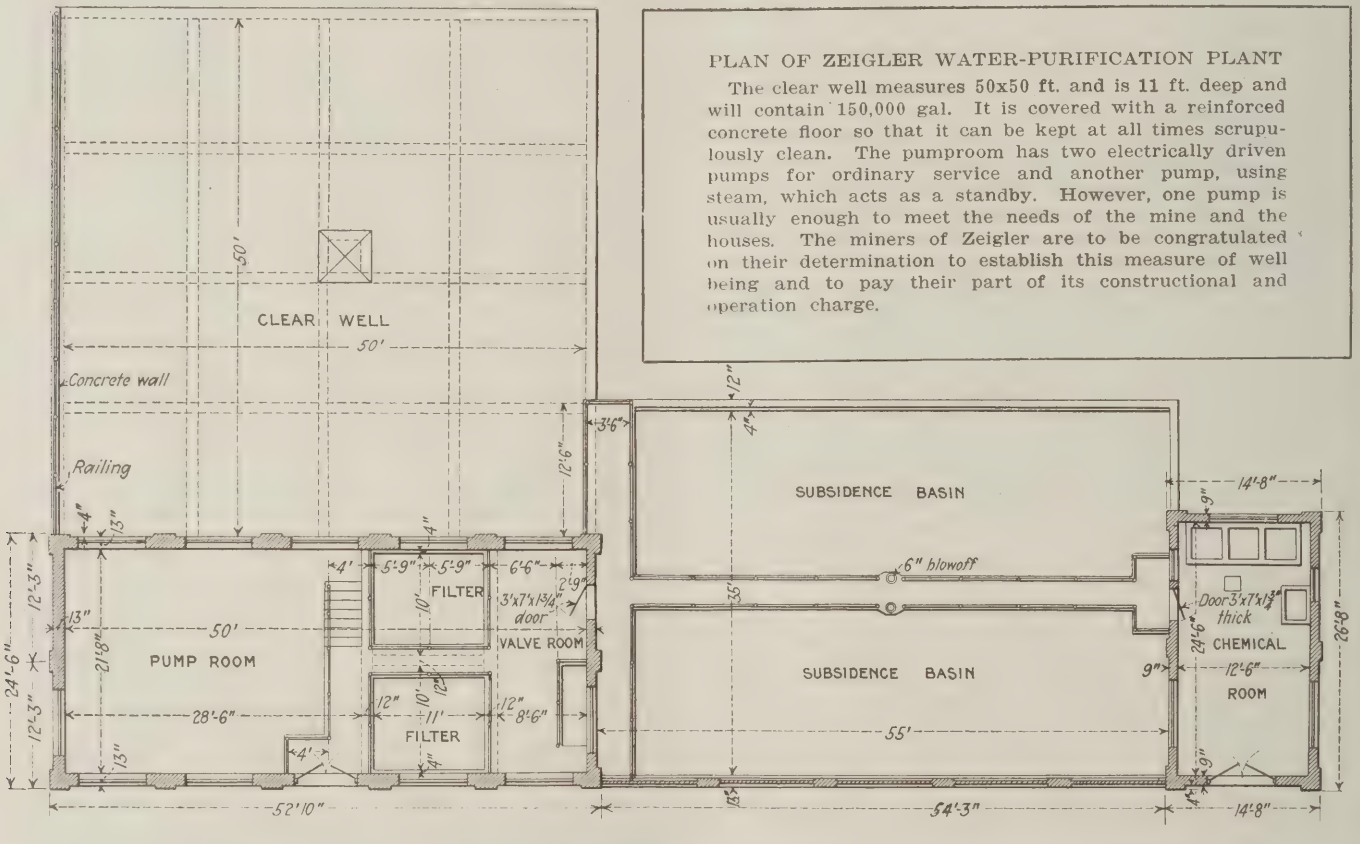
The water then flows to one or the other of two subsidence or settling basins. These are concrete tanks of comparatively large size. As two such tanks are employed, one may be cleaned while the other is in operation. Suitable drain pipes have been provided so that either tank may be emptied and washed out with a hose or even scrubbed with a broom, if necessary. The chemicals introduced into the raw water reduce to a flocculent condition the dissolved impurities carried by it. Individual masses of this nature, for the most part, settle out of the water in the subsidence basin.

*Associate Editor, *Coal Age*.

WATER PURIFICATION PLANT AT TOWN OF ZEIGLER, IN WHICH BELL & ZOLLER MINING CO.'S EMPLOYEES LIVE

On the left is the chemical room, where soda and alum are added, which causes a softening of the water. The impurities, being in a flocculent condition, have to be passed through one of two settling basins, the concrete and brick wall of which may be seen in the illustration. On the right is the building which houses the pumproom and filters. The subsidence basins, being used alternately, can be conveniently washed out with a hose or scrubbed with a broom.

In order to assure complete removal of this material, however, the water, upon leaving the settling tank, is passed through a sand filter. Two of these units are provided. The water normally flows through them from the top downward. Provision is made, however, for washing these filters by forcing clean water upward through the sand, thus not only violently agitating it but by this means dislodging, removing and carrying away the material which has been removed from the water and which adheres to each sand particle. This process requires only a short time.



From the sand filters, of which, like the chemical and subsidence tanks, there are two, so that one may be kept in use while the other is being cleaned, the water goes to the clear well, where the requisite amount of chlorine is introduced. This is a 150,000-gallon concrete tank built immediately alongside the pump and filter plant. It is covered by a reinforced-concrete floor, so that all foreign material, such as dust and dirt, is effectively excluded.

Two electrically driven pumps are provided for ordinary service and one steam pump for emergency. The ordinary or house service pumps are Manistee Roturbo centrifugals, direct connected to 40-hp. three-phase 440-volt 60-cycle alternating-current electric motors operating at 1,750 r.p.m., with full automatic control. The capacity of each pump is 600 gallons per minute against a 150-ft. head. Ordinarily one pump will supply the needs of the entire water system.

These pumps are connected to the mains in such manner as to "float" upon them. That is, the mains lead from an elevated tank to the mine and the various house-supply lines, the pumps being connected to them at an intermediate point. The pumps thus supply water to the mine and houses at tank pressure, any surplus going to the tank and any deficiency being made up from it. The elevated tank thus acts as an equalizer between pump and mains.

A duplex steam-driven piston pump is installed alongside the two centrifugals. This pump is arranged to take care of the regular service between the clear well and mains, furnishing filtered water to the tank and houses, as well as the mine. In case of fire this pump can be used, if need be, the connection being arranged so that in case of failure of filtered water from the tank and basin, raw water from the larger reservoir can be pumped directly into the mains for fire service.

The steam-driven pump was installed as auxiliary to the centrifugals because the transmission lines from the mine power house might fail to deliver the needed current. Steam under any ordinary circumstances always would be available and it was therefore deemed wise to install both types of pumping machines to insure continuous service at all times. This arrangement, therefore, insures maximum reliability in service and that the supply of water will never fail.

PLAN OF ZEIGLER WATER-PURIFICATION PLANT

The clear well measures 50x50 ft. and is 11 ft. deep and will contain 150,000 gal. It is covered with a reinforced concrete floor so that it can be kept at all times scrupulously clean. The pumproom has two electrically driven pumps for ordinary service and another pump, using steam, which acts as a standby. However, one pump is usually enough to meet the needs of the mine and the houses. The miners of Zeigler are to be congratulated on their determination to establish this measure of well being and to pay their part of its constructional and operation charge.

Coal cost at any mining operation is made up of many factors, among which the general health of the community cannot be overlooked. For a mining company to undertake the construction and operation of water-works to furnish water to a municipality is perhaps somewhat unusual, but that such a procedure is financially warranted under the conditions existing at Zeigler can hardly be doubted. The return to the mining company on such a venture will not in any wise be direct. In other words, it will not consist in the direct revenue derived from furnishing the town with water but in the indirect and somewhat intangible returns obtained because of the better health of the mining community and the consequent greater contentment, higher efficiency and better morale of the company workmen.

Safe and Economical Ways of Hanging Electric Cables In Mine Shafts or Boreholes

Danger of Stretching Copper and Lowering Capacity Thereby—Zigzagged Copper May Be Brought Down by Falling Material—Protecting Lashing by Cable Clamps—Cable Supports Which Bend Cable

By Frank W. Cramer*
Johnstown, Pa.

ONE of the first problems to be solved when electricity is to be installed in a mine is that of placing the feeder lines. It has been demonstrated many times that the electrified mine is more economical than one where the work of haulage is done by a steam hoist and drainage is effected by steam pumps with their long lines of pipe and the important heat losses consequent thereon.

It must be borne in mind, however, that it is essential to efficiency that the electrical feeders be properly designed and installed. If they are so planned and erected they may be forgotten with safety, but if haphazard construction and the wrong cable be used, the feeder system may be a source of continuous trouble.

Feeder cables necessarily follow routes which differ widely, for the means of reaching the mine may be anything from a drift to perhaps a 1,000-ft. shaft. Consequently the support or suspension of these cables cannot have a common solution. Slope or drift mines offer few difficulties, but where the approach is by shafts or boreholes of considerable depth the suspension or supporting of the feeders must be given careful thought. In many installations in the mining field such consideration was not given before the feeders were installed, and, as a result, the cable was either pulled apart or so stretched by its own weight that the cross-sectional area of the copper was considerably reduced.

Cable if Wrongly Strung May Fall Later

If this break occurred after the haulage had been electrified, it delayed or shut down the operations, with much consequent expense. If the cable was stretched, its carrying capacity was reduced and the voltage drop in the line increased. For some reason or other data for installing such cables has not been given wide publication, and the manufacturers, knowing the difficulties of this class of work and not being familiar with the particular mine, usually inform the purchaser, if he asks them how the cable should be installed, that the cable must be supported at certain distances and then leave it to him to devise the means of support.

This information may not mean much to the mine superintendent, for the design of the shaft may be such that it is impossible to support the cable at such intervals, and in other instances the cable having to be placed in a borehole, a top support is all he can provide. The purpose of this article is to describe briefly two successful methods of supporting cables, one for shafts and the other for boreholes.

Fortunately, most hoisting shafts are used also for airways and a space for air is left at either side of the cageway. In this part of the cross-section cables can be placed. For this work they should be of the lead-covered armored type with a layer of jute over the armor that has been impregnated so as to resist the attacks of mine water. The armor will protect the lead from mechanical injury. The usual size for the direct-current feeder used for this class of work is 1,000,000 cm. A cable of this kind weighs about 8 lb. to the foot. If a 2,200 or 6,600-volt 3-phase alternating-current cable of 0 wire is used, the weight will be about the same. An effort usually is made to set supports at about 30-ft. intervals. These supports are fastened to the cross timbers and are so designed that each of them will throw a bend in the cable at the point of attachment.

Several shaft installations have cables of this sort zigzagged across the bracing of the cageway. This is satisfactory so long as a heavy load does not fall down the shaft and hit them or so long as none of the timbers supporting the cable rots away and falls. If either of these accidents should happen the cable would be likely to be torn loose from its supports and break, with the ultimate result perhaps that the cable would be found later at the bottom of the shaft.

To avoid accidents such as this, much consideration was given to the design of the cable supports prior to the suspension in a 500-ft. shaft of four 1,000,000-c.m. direct-current feeder cables and one 3-phase 2,200-volt 0 cable. In installing a cable in a shaft of such a depth it was evident that support must be afforded not only at the top but at several points in its length, for fear that the weight of the cable itself would either break or stretch the lead and copper and perhaps ruin

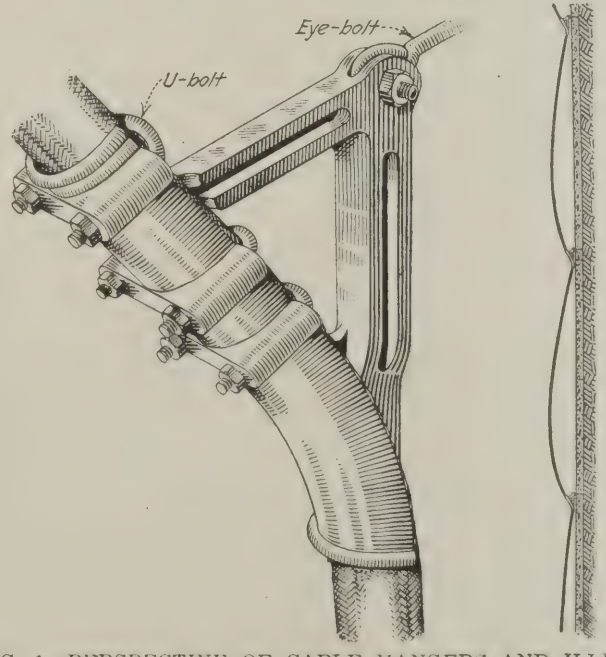


FIG. 1—PERSPECTIVE OF CABLE HANGERS AND ILLUSTRATION SHOWING CABLE IN MINE SHAFT
The grip on the cable is not sufficient to injure the lead sheathing but is enough in conjunction with the wavelike shape of the clamping groove to hold the cable without slippage.

*Assistant electrical engineer, Cambria Steel Co.

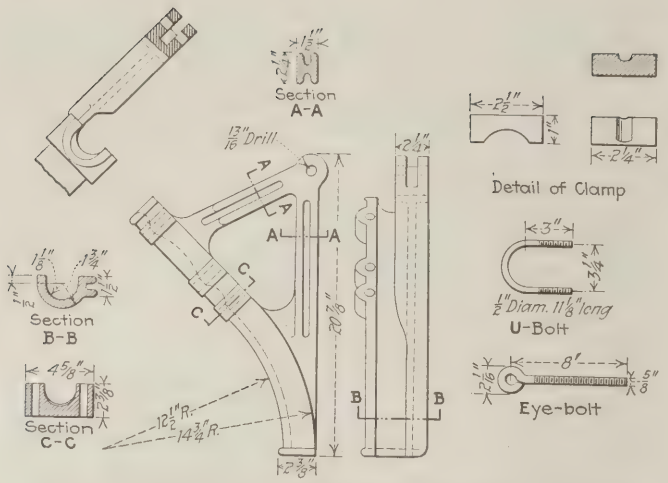

FIG. 2—DETAILS OF HANGER FOR SHAFT CABLE

When these hangers are set 25 ft. apart they effectually and without undue compression hold the cable in place and would do so even should a hanger be knocked loose. They serve both to suspend and to support the cable.

the feeder before it was installed. To avoid this, a $\frac{7}{8}$-in. steel cable was wound around the drum of a hoisting engine and used as a support in lowering.

The reel of feeder cable was placed on trunnions, rigged up with a brake and located on the opposite side of the shaft from the hoist. The two cables were then fed over bull wheels until they met at the top of the shaft, where they were tied together with half hitches of $\frac{1}{2}$-in. rope. To prevent this rope from slipping cable clamps were fastened on the steel cable below each hitch. Both cables were then lowered 30 ft. and tied again. This process was continued until 750 ft. of the lead cable was lowered, which was long enough both to go to the bottom of the shaft and to reach the distributing point in the mine.

Prior to this the cable supports shown in Figs. 1 and 2 were fastened to the side of the shaft airway, five of them in a row, one for each cable, spaced 2 ft. apart and supported by $\frac{5}{8}$-in. expansion eyebolts and jackets. The rows of brackets were placed at 25-ft. vertical intervals. As this shaft is concreted throughout its entire depth, the eyebolts which fit in the clevis of the hanger have a solid bearing in the side of the shaft. The groove in which the cable lies is not a smooth curve, but a series of valleys and rises so designed that when the cable is fastened with the three clamps provided for each hanger, it cannot slip.

After the cable had been lowered it was moved into position at the bottom hanger and the clamps put on. Little pressure need be put on these clamps, for a light grip on the jute will prevent the cable from slipping and a tight grip may crush the lead. After the clamps were put on, the steel-wire support was removed at that point and the two cables were raised or lowered by the engine, so that the lead cable could be put into its place in the second hanger from the bottom of the shaft. This method enabled the several feeders to be set in proper alignment and made handling easy. The process was continued to the top of the shaft, where the last hanger curved the cables into position to enter the conduit lines which passed to the substation.

As can be seen in Fig. 2, the support is so designed that the cables do not rest against the wall of the shaft, and in consequence no water pockets can form. The cables are so placed that falling material is not likely to hit them, and as they are supported by concrete instead of by timbers, which are likely to rot, this is a safe method of anchoring. Dirt will not harm them, as cables of this nature are designed with the expectation that they will be buried in direct contact with the earth. Water dripping down the shaft likewise will leave them unharmed. Each hanger supports just 25 ft. of cable, as is shown by the bend in the alignment of the cable. If an eyebolt should break or rust off no injury will be done, as the next hanger above will easily carry the double load, for the weight of 50 ft. of the feeder will not stretch the lead.

As it usually is difficult and expensive to run high-tension circuits for any long distance inside the mine the policy is to put them down a borehole near the point where the power is needed. Consequently at boreholes it usually is alternating-current lines, which require 3-phase cable, that have to be installed. The mine laws of Pennsylvania compel mine owners to put an oil switch, disconnecting switches and lightning protection at all high-tension boreholes, and if more than 500 ft. from the substation, similar equipment for low-tension circuits. This makes it desirable to build a small house over each borehole, and provisions can be made in the design of this house for the support of the lead cables that go down into the mine. Such a design is shown in Fig. 3.

A corporation contemplating several borehole installations will find it advantageous to prepare a standard design for these houses, as this will not only reduce their cost but also give the field man definite instructions as to what is required of him. With a design such as shown the overhead lines can be dead-ended from any direction, and the house and the equipment always is arranged in the same way. These houses are kept locked, and if the circuit breaker in the mine is properly set the only time the one on top will open is for trouble on the lead cable. The houses are inspected at least once a week to make sure everything is in working order.

In boreholes up to 300 ft. in depth it is safe to clamp this type of cable with a long wooden clamp at the

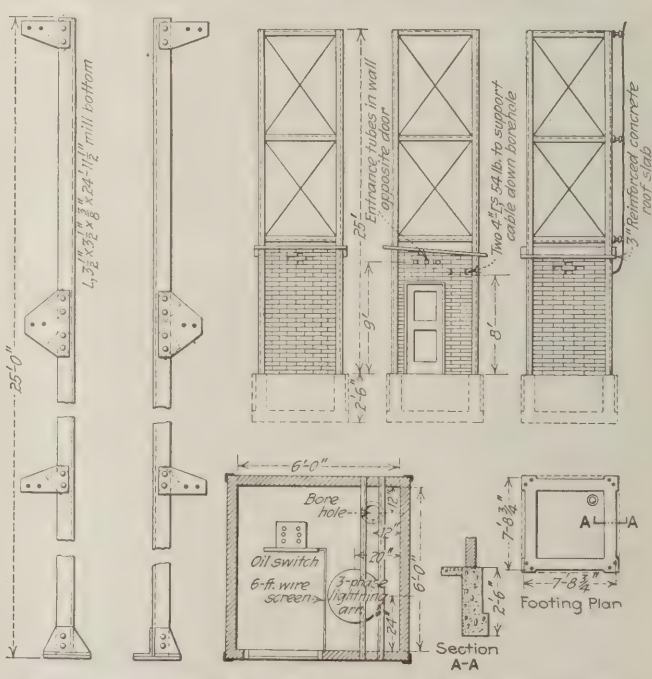

FIG. 3—HOUSE OVER CABLE-CARRYING BOREHOLE

Standard construction for housing oil switch, disconnecting switches and lightning protection over boreholes drilled for power purposes. Note also the channel support for the hanging of feeder cables and the ventilation holes near the roof of the room. The foundations may be made deeper if necessary to reach solid earth.

top and to use this as a top support. In addition to this two L condulets should be used on the lower end of the conduit. With this combination the cable is suspended from the top and also is supported on the bottom by turns which prevent it from slipping. This has the effect of literally standing the cable on end, as the bottom support takes most of the weight.

If only a top support is used the weight of the cable may either break the lead or at least stretch the copper near the support, thus reducing the carrying capacity. Several successful installations of this kind are now in use. If the engineers desire to support the cable entirely from the top, the manufacturers may be able to furnish a special cable that will have, in addition to the armor, a layer of supporting steel wire around the outside. They should be consulted as to the length that can be hung in this manner.

In conclusion it is well to emphasize again the necessity of careful thought and engineering in the installation of the feeder cables of mines. The operation is always dependent on the continuous functioning of these lines. A haphazard job always will be a source of trouble, but a well-planned and well-executed installation can be depended upon for service at all times.

Two Explosions, One in Dawson, N. M., and One in Dunsmuir, B. C., Kill Many Men

IN AN explosion, the cause of which possibly may never be determined, 120 men were killed, on Thursday, Feb. 8, in Mine No. 1, operated by the Stag Canyon Branch of the Phelps Dodge Corporation and located at Dawson, N. M. Apparently 141 men had checked into the mine and of these 19 had left when, at 2:30 p.m., a terrific explosion occurred, only two of those underground managing to escape. The concrete mine portal was demolished by the force of the explosion, thus hampering the rescue work.

Most of the men were at some distance within the mine, only two, a motorman and a nipper, being found near the mine mouth. The two men who walked out were in the pillar work to the left of the main entry.

The time at which the explosion occurred would suggest at once in most mines that a shot had blown out, fired by a man who was preparing to go home, but at these mines of the Phelps Dodge Corporation the miners do not so much as charge their own shotholes, and, after they are charged by "shotfirers"—or should they be called "shot loaders"?—they are fired from the surface by a system of wiring and then only after every man is out of the mine. It is interesting to record what safety precautions are taken at these mines, where the humidity, it must be remembered, often is extremely low. In this respect conditions are much worse in the states of Utah and New Mexico than in any Eastern mines, and the Phelps Dodge Corporation has gone as far as, or further than, any other mining company in its endeavor to maintain the safety of its employees.

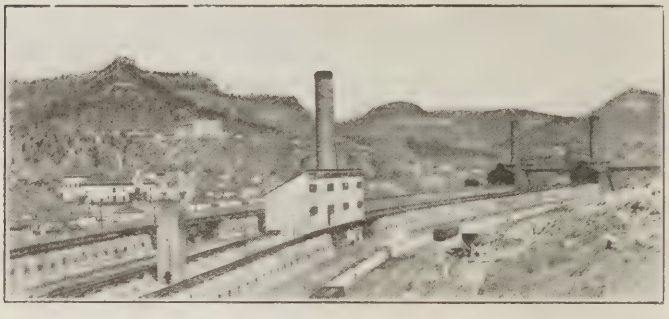
Though the mine has no gas—on that both the state mine inspector and the company are in agreement—no naked lights are used, the men carrying battery lamps. The shot loaders are instructed that no shots are to be fired unless the holes are drilled 6 in. in the clear and 12 in. or over from the rib. All shots are to be tamped with adobe to the collar and not more than 1½ lb.—three sticks—of explosive may be placed in each hole. No shot which is on the solid may be fired, and all machine cuttings must be loaded out of the entry or the room before a charge is exploded. The miner drills his own holes but is not allowed to charge them.

The shot loader in making his rounds takes with him the necessary powder and in accordance with his judgment charges each blast with the quantity of explosive he deems necessary, keeping an account of the quantity used at each place and charging the miner accordingly. All explosives are taken into the mine in a closed box which is asbestos-lined. When being transported to the workings the box is placed in a mine car and taken to the distributing points by one special motorman. All explosives not used during any shift are promptly returned to the magazine, and the shot loader is credited with them.

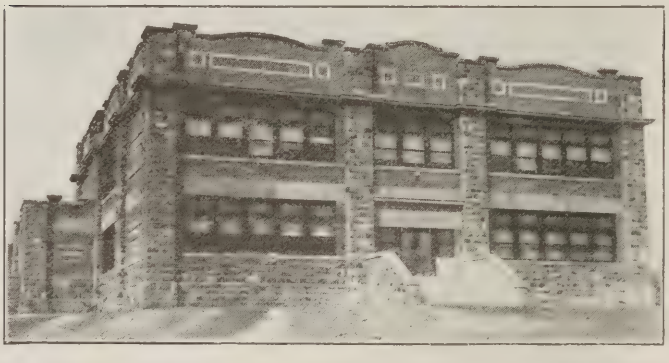
The mines would be as dry as tinder were it not for an extensive sprinkling system, the piping being carried even into the rooms. The coal—at least some of it—is cut by machine and gathered by storage-battery locomotives.

It is possible that the explosion came from a blown-out shot, a hole being charged by some miner who wanted to get a little more coal than the previous shot had afforded. If so it must have been done with "bootleg" powder. It is within the bounds of possibility also that some man connected up with the trolley wiring a shot that had failed in the previous night's firing. If he did, the act was a violation of the company's rules.

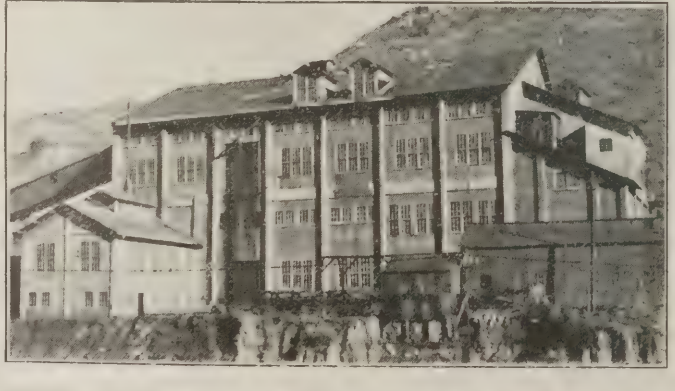
The probability that the explosion was due to a blown-out shot makes it interesting to know whether the pockets of the mine workers are carefully inspected as they enter the mine, as was stated in a dispatch to the *New York Times*. The officials at the New York office are not able to confirm or question this statement. It seems that it must have been an unauthorized shothole which was the cause of the explosion, for the New York office fails to recall a single case where an explosion has been caused by the nightly practice of firing all the shots by a current from the surface—a severe test of the general safety of the mine and of the freedom of authorized shots from blow outs.



Nearly ten years ago—Oct. 22, 1913—an accident occurred in Mine No. 2 of the same company and 263 men, including 2 rescue men, were killed. This accident doubtless was caused by an unauthorized shot. The jury so decided, for the evidence was overwhelming. Of course, a short-circuit resulting from a fall of the trolley wire or from a broken or stripped cable might have started the explosion, but it is not likely that the disaster was thus caused.



Another explosion occurred on the same day but at the mine of the Canadian Collieries (Dunsmuir) Ltd., Dunsmuir, B. C., on Vancouver Island. A night shift of 300 men was at work. The explosion occurred in No. 2 east drift, fifteen men being killed by the force of the explosion and eighteen others probably from afterdamp. Six are in the hospital hovering between life and death. It is said that many of the men would have been saved if they stayed in their places. As it was, they ran out and tried to pass through the afterdamp at the entrance of No. 2 west drift. About 20 of the men killed were Chinese.



The mine workings were badly caved by the explosion, and the rescue work much hampered. Arthur Watson, one of the four firebosses, managed to bring out two Chinese with him and then re-entered the mine with others and brought out alive two of six Chinese whom he found huddled in a heap on one of the levels. The other four were dead.

Mining Two Beds at Gray Slope with Heavy Parting

Methods Adopted in Extracting Two Thin Seams, One 28 In. and the Other 30 In. Thick, Having Two to Six Feet of Intervening Rock—All Coal Recovered

By D. C. Ashmead*
Kingston, Pa.

IN ORDER to maintain production not only at individual collieries but throughout the anthracite field, operators are being forced year by year to turn to the thinner beds of the region. In 1882 Lackawanna County first began to mine beds of coal thinner than 3 ft., and by 1922 about 25 per cent of the beds being mined were of this thickness.

A prominent engineer in the anthracite region has pointed out that every colliery has a certain stand-by operating expense. No matter what the output is, this expense remains constant, unless, indeed, the production is forced beyond that for which the plant was designed. To get this large output would, however, require the installation of a larger plant, whereupon the stand-by expense would be increased proportionately.

If the production of a colliery is low compared with the output for which it is designed the cost of producing the coal is high, even without regard to this stand-by expense. When to this cost is added a stand-by charge which has to be distributed over a small tonnage the cost of production is found to be unreasonably high.

If the production is increased, the stand-by charge per ton is decreased. When the production of a colliery is brought nearly up to the maximum production for any given stand-by charge, the colliery will be operated at maximum economy.

In a colliery that is continually increasing its output it would be found, if the figures were available, that the cost of production changes in cycles, for before such increase in tonnage could be obtained more machinery would have to be installed and more cost for supervision would have to be incurred and the cost while the tonrage was being brought in line with the stand-by cost inevitably would be excessive.

Let us consider, therefore, a colliery the production of which has reached a maximum and has begun to decline due to the exhaustion of the better beds. The stand-by charges in this case remain constant, but, the production decreasing, the cost per ton increases. It may well reach a point where the stand-by charges and the operating charges per ton of product are higher than can be realized by the sale of the coal.

Thinner Beds Bolster Declining Tonnage

These conditions force the operator and the engineer to turn to new sources of supply so that production may be maintained at a desirable constant. The only way in which to increase the tonnage in many mines is to turn to the thinner beds of coal. The question arises, therefore, can the coal from these thin beds, the mining of which is so expensive, be combined with the mining of thicker coal so that the average cost of all the coal, taking into consideration the stand-by charges per ton, will be lower than the price per ton which the coal will bring? It is necessary always to consider whether operating the thin beds will or will not make the cost per ton greater than it would be if only the thicker coal was mined and the tonnage of coal was accordingly lowered.

As it usually costs more to produce coal from thin beds than from thick and as the conditions outlined are causing operators to undertake the mining of those that are thin the engineer is interested in learning what new

*Assistant editor, *Coal Age*.

FIG. 1

First Mining, Both Beds

The solid lines show the workings in the upper of the two beds and the dotted lines outline the excavations in the lower seam. The rooms, the ungobbed width of which is 10 to 12 ft., are driven on 50-ft. centers. It will be noted that much more coal has been removed in the lower than in the upper bed. This is done so that the rock between beds can be gobbed in the widened portion of the lower room. Whatever coal is left in the pillar of that room—and it is heavily cut into by crosscuts—can and will be removed from the roadway of the next room inby.

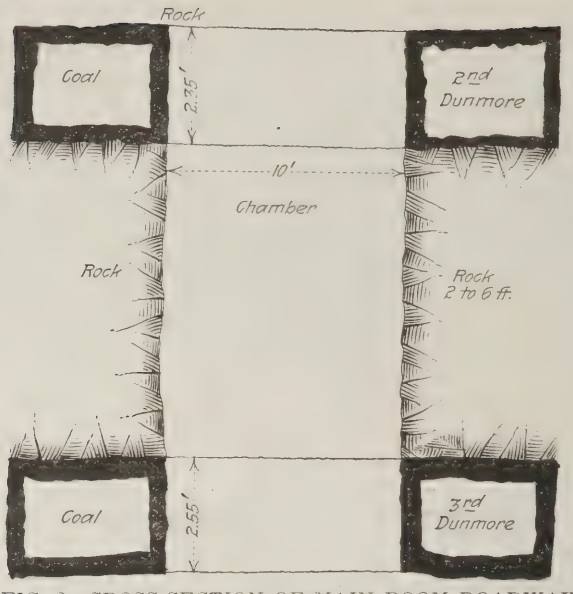

FIG. 2—CROSS-SECTION OF MAIN ROOM ROADWAY

The roadway is driven through the coal of both beds and the rock is between them. This is done, however much rock there may be in the parting. The lower seam is the Third and the upper seam is the Second Dunmore. In some parts of the field the Second and Third Dunmore beds are one, but in the Forest City section the parting has become so big that they are regarded as two separate seams.

methods the coal companies are using to extract these thinner seams.

The Pennsylvania Coal Co. and its sister corporation the Hillside Coal & Iron Co., have done much experimenting in this direction, and this article will deal with the mining of the Second and Third Dunmore beds at the Gray Slope of the Forest City Colliery of the Hillside Coal & Iron Co.

Both beds lie comparatively flat. The Second Dunmore bed is 2.35 ft. thick and the Third Dunmore seam is slightly thicker, and will average 2.55 ft. in thickness. A parting of rock from 2 to 6 ft. in thickness lies between the two beds.

About every 500 ft. a heading and airway are turned at right angles to the main roadway and a pillar of not less than 50 ft. is left between each heading and its airway. This, it is true, is only the theory of operation, for, owing to the irregularity of the level of the coal seam, it cannot be followed strictly. Instead the heading and airway are driven along the contours of the coal or slightly uphill, so that the water in them will be self-draining. Consequently the pillar between the heading and airway may be greater than 50 ft., but in no place is it allowed to be less than that. In driving the heading and airway the parting is taken down, and the height of the heading is that of the thickness of the two beds of coal plus that of the parting. Sufficient coal is taken from the bottom bed to allow all the rock encountered to be gobbed in the excavation made in that seam except in some cases where it is thought advisable to haul the rock to the surface.

From the pair of headings, chambers are driven on 50-ft. centers and extended till they come within 25 ft. of the airway of the next parallel set of headings. These chambers are only from 10 to 12 ft. wide, in the Second Dunmore bed as is shown in Fig. 1. They are driven in both the Second and Third Dunmore beds, the rock parting between the seams being removed to a width of 10 to 12 ft. and the Third Dunmore bed being widened in the coal to a depth of at least 25 ft. Fig. 2 shows a cross-section of the two beds of coal and the dimensions of the roadways.

As the latter are driven up, sufficient coal is taken out of the Third Dunmore bed to provide for the stowage of rock from the parting between the beds. If in order to gob the rock it is not necessary to remove all the coal between the roadway and the center line of the pillar the space that is needed is not provided along the line of the roadway but in wide crosscuts driven through the pillar. The work in the Third Dunmore bed is delineated in Fig. 1 by broken lines. In shooting the coal care is taken to place the shot so that it will throw the coal in the direction of the track, which thus will need only a minimum of handling.

The rock parting thus filled into the voids of the lower bed acts as a support for the one above. In Fig. 4 it will be noted that in some places it was necessary to remove all the coal from areas as large as 200x350 ft. in order to provide adequate space for the gobbing of the rock parting.

FIG. 3

Second Mining, Upper Bed

This also shows a large area where first mining alone has been done. It will be noted that all the coal ultimately is taken out and that in the first mining only 20 per cent is removed. This coal is relatively easy to load as it lies well above the top of the mine car.

FIG. 4

Second Mining, Lower Bed

This shows how complete is the extraction of coal. In the whole area shown all the pillars have been extracted except along airways and haulageways which have to be maintained for future work and a line of pillars along a room road which is being used as a subsidiary roadway. The area, however, includes some first mining, and that accounts for some of the pillars.

When the chambers are driven to their limit, second mining can be started, but usually nothing further is done until eight or nine rooms have been driven their full length. In the second mining all the coal in the Second Dunmore bed is removed and loaded into mine cars. As these are below the level of the coal in this upper bed, the difficulty of loading is reduced and simplified, for the coal can be shoveled into the mine cars without being lifted from the bottom. As second mining progresses the coal that was left in the pillars on the first mining of the Third Dunmore bed is removed and loaded out. This coal is handled with more difficulty, for the top of the mine car is above the top of the Third Dunmore bed. This coal in many cases has to be reshoveled. This pillar-drawing operation continues until the pillars are drawn back to within 25 ft. of the heading. Fig. 4 shows the area of coal removed in the second mining of the Third Dunmore bed and Fig. 3 shows that extracted from the Second Dunmore bed.

The roof above this latter bed is allowed to cave, but the rock packing in the Third Dunmore bed tends to hold up the rock parting. Thus the total settlement is much reduced. It is the intention ultimately to pull back the pillars left to support the headings and airways.

By this method of mining all the coal from two thin beds is loaded out and none lost except by spillage. By the mining of these two beds of coal the production of the Forest City colliery is maintained and its stand-by charges per ton thereby reduced.

Dangers in Shaft Mines and Their Cure

"LESSONS from the Granite Mountain Shaft Fire," by Daniel Harrington, Bulletin 188 of the U. S. Bureau of Mines, 50 pp., is a remarkable record of a mine fire, its disastrous results and its important lessons. It is a welcome addition to the literature of fire handling and prevention. The Bureau of Mines does not usually publish reports such as these, but in this instance the North Butte Mining Co. consented, not unwillingly, to have all the details made public for the benefit of industry. To this public-spirited act the mining fraternity is greatly indebted. A well-managed mine was greatly damaged and, worse yet, 163 men were killed by this fire due to a misfortune in the handling, perhaps even to the ill-handling, of an electric cable during installation.

The book recommends that not only hemp lashings but a positive clamp also be placed on a cable when it is being lowered, even if the clamp should crush and destroy the length of cable occupied by that fastening, the placing of cables in boreholes, the latter to be drilled in ground that will not move and to be reached for support and supervision at the several levels by cross roadways, shut off by airtight doors. If boreholes are not used the cable should be put in a downcast shaft. If the cable in an upcast should fire, the fan should be reversed so as to exhaust the gases from the cable to the open air. The hoisting shafts should be lined with concrete and, if sliding ground renders this impracticable, all timbering should be coated with cement, a cement gun being a suitable method of performing that work.

Connections should not be made between mines except for drainage and fire extinguishment. Where made they should be closed by steel or concrete on concrete frames and with edges sealed with concrete. Doors should not be hung inside concrete frames where movement of the measures may make them inoperable. They should be hung so as to lay flush against the smooth surface of the concrete frame. Other advice given relates to signboards, making doors which will not open when the ventilation is reversed, double doors, signboards, maps, leakage of gas through doors, signals, fire protection, fire warnings, organization of rescue work, the building of safety chambers by men imprisoned and so forth.

THE COLLECTION OF SAMPLES from tipples for the various coal exchanges, performed by the Bureau of Mines, showed the need of a portable coal-crushing and sample-reducing plant to obtain mechanically a laboratory sample from the gross sample. A sample crushing plant mounted on a Ford truck has been constructed and will be tried out in connection with the fuel-economy survey now being conducted in the District of Columbia, and any defects found in the apparatus will be remedied.

Problems of Operating Men

Standard Rule for Estimating Available Tonnage Per Acre

Need of Standard Rule in Estimating Acre Tonnage —Percentage of Extraction Varies in Each Case—Percentage of Screenings Also Variable

AWHILE ago a question was asked by a Colorado engineer, as to the method of estimating the available tonnage contained in a seam of coal. The answer given by the editor of *Coal Age*, at that time, referred to the common rule of thumb for estimating the tonnage of coal per acre, on a basis of 1,000 tons, per foot-acre, which was later increaesd to 100-tons per inch-acre, in the seam.

This increase in estimating available tonnage was owing to improved methods of mining giving a larger percentage of extraction. The question was brought up again by another inquirer, Dec. 14, p. 961, who referred to certain tables giving the tonnage of coal underlying an acre of land, for varying thicknesses of seam.

Since reading the explanation given in answer to this second inquirer, it has occurred to me that there is no good reason why we should not have a standard rule for estimating the acre-tonnage of coal. For example, the old rule of thumb makes no allowance for percentage of extraction and amount of screenings, as it can hardly be assumed to refer to mine-run coal.

Formulating a Standard Rule

In seeking for a standard rule, let us assume the weight of bituminous coal underlying an acre of land, in a flat seam, as stated in the reply, will average 1,800 short tons per foot-acre. Also, it is assumed that the same weight expressed in long tons (2,240-lb.) is the average for anthracite coal, per foot-acre. It is difficult to understand, however, why anthracite coal is always estimated in long tons, in the mining of the coal. To the consumer, a ton of this coal is 2,000-lb.

Now, taking the basis of computation for average bituminous coal as 1,800 short tons, per foot-acre; or 1,800 long tons of anthracite, per foot-acre, it should be easy to multiply this weight by any assumed percentage of extraction, which would give the possible available tonnage, per foot-acre, assuming mine-run coal. For screened coal (lump) there should be another deduction allowing for the percentage of screenings. This, to my mind, would give a good standard rule for estimating acre-tonnage in a flat seam. As has been stated, if the seam is inclined, this result must be divided by the cosine of the angle of inclination.

Apparently, there is a great deal of bunk in connection with the coal trade, not alone in items of this kind, but in others. For instance, there is a very acute shortage of cars throughout the coal fields of America at this time, though it is not clear whether this affects the anthracite field.

Again, whenever there is a holiday, great stress is laid on the loss of tonnage by reason of the holiday. Now, if a mine receives but two supplies of cars a week and loaders are idle half the time, how can an occasional holiday have any serious effect on the result?

Many other kinds of bunk are being put over in these times. Indeed the instances are so numerous that the period from the beginning of the great war till now might well be called the "Age of bunk" and people who are chiefly concerned in the results that follow might well be classed as "bunkers."

J. F. Healy, Chief Engineer,
Omar, W. Va. Main Island Creek Coal Co.

Still Mine Disasters Continue

Recent mine disasters call attention to need of more stringent laws—Responsibility for conditions in Pennsylvania—Increasing safety in mines.

IT IS painful to be reminded, by the frequent recurrence of mine disasters, that there is something lacking in our administration of affairs in the operation of the mines. Following every great disaster, investigation places the blame on someone's disregard of rules and regulations, or emphasizes the need of greater stringency in our mining laws.

Whatever the reasons given for these occurrences, we are compelled to take the stand that the lives of brave men have been sacrificed and widows and orphans left without material support. I am not going to refer here to explosions in Alabama, Illinois or any state other than of our own Pennsylvania.

According to the most recent report of the explosion at the Reilly Mine No. 1, Spangler, Pa., which occurred Nov. 6 1922, seventy-seven lives were lost. The question comes home to us, Why could not this terrible disaster have been prevented?

Does the Pennsylvania Law Invite Disaster?

While I agree with the decision reached by those who investigated that disaster, and placed the blame for the occurrence on the shoulders of the mine owners and the management of the mine, the fact remains that there was no violation of the law. Under the revised mining statutes of Pennsylvania, the mine operator is made the supreme judge of what is safe and what is unsafe in the operation of the mine.

In my opinion, this feature of the Pennsylvania law invites mine disasters, inasmuch as it authorizes every mine superintendent to follow his own sweet will or, in other words, to do as he pleases in the selection of a competent mine foreman, to take charge of his mine.

Viewed from another angle and considering the responsibility of the State Department of Mines and its staff of state mine inspectors, one is led to ask, Why did not this branch of the government act in its capacity to safeguard the Spangler mine? The answer would seem to be that the Department of Mines could only act in an advisory manner, the authority of the mine superintendent being supreme, in the eyes of the law.

Would that this disaster could teach us a lesson and cause the enactment of a law that would properly safeguard the work and insure the largest percentage of extraction of the coal. In plain words, the weakness of the Pennsylvania law is responsible for the Spangler disaster.

In concluding, allow me to ask one or two questions that I would like to see presented for the consideration of readers of *Coal Age*, in the hopes of getting expressions of their opinion.

1. In what respects can our state mining laws be improved? 2. Should firebosses and safety inspectors be employed by the company or by the state or federal government? 3. Can mine explosions be prevented and, if so, by what means? C. W. ATKINS

Parnassus, Pa.

Improved Status of Company Stores

Former dissatisfaction replaced by growing popularity —Better business methods employed—The mine foreman a booster for the store.

NOT many years ago, it will be remembered, the company store and everything connected with it was particularly distasteful to the average miner. That this individual was, in most cases, a bad business man and prone to regard the store where he did his trading as one of the "pluck-me" type cannot be denied.

To overcome these hindrances has required much study of human nature and the exercise of diplomacy on the part of the store manager. As a result, however, much of this former dissatisfaction has been steadily disappearing and trading at the company store is now, with few exceptions, more than ever popular.

One thing that has contributed to this condition is the fact that the wise manager is learning how to help the miner, by insisting on better business methods between the store and the miner's family. Again, on the other hand, the store manager is learning that it pays him to compete with the outside stores, in his neighborhood, by keeping on hand a small line of the "cheap-John" goods.

These cheaper goods serve their purpose well by enabling the customer to compare their quality and price with goods of a more substantial make. There are few customers but who wisely conclude that money will be saved by buying the better grade of merchandise at a slightly higher price.

Putting the Store on a Paying Basis

Only recently, I became much interested in a young fellow who had undertaken the job of putting seven very unpopular company stores onto a paying basis. Knowing that I came into daily contact with many successful store managers, he assumed that I could give him some valuable points in reference to getting the miners to patronize these company stores.

In response to his many inquiries, I unfolded to him how many successful stores had come into their own. In this respect, one of the chief points to be emphasized, I assured him, was getting on good terms with the mine foreman. At times, that individual would look for some return favor, in proportion as he was able to boost the trade among his men.

A little talk along this line convinced my friend that it would be good policy to grease the way; and the trial that he made, a little later, proved his conclusion correct. Many mine foremen, in loyalty to the company's interests expected nothing in return for their efforts on behalf of the stores. Others became boosters, through the application of a little grease.

Though the plan has been working but a comparatively short time in these stores, the new manager informed me a while ago that he is sure that more has been accomplished through the mine foremen than he could ever have hoped to accomplish himself. In my opinion, he is quite right and the greasing of an occasional foreman was merely a business proposition when it became necessary.

Speaking of ways of improving mining practice to which reference has been made by some recent writers, in *Coal Age*, it appears to me that the company-store proposition comes in for its share of careful consideration. It does not pay any company or management to attempt to run a company store, unless it can hold its own in competition with other similar stores, both in respect to prices and quality of goods.

In some instances, to my knowledge, inducements have been offered mine foremen, by outside stores, to secure their goodwill and get them to trade there. However, any foreman who will use his good offices, in favor of an outside store, in preference to the store operated by his company, is guilty of disloyalty to the company. GEORGE EDWARDS.

Pikeville, Ky.

Personal Touch in Management

Influence of management on accident rating—Observations on visit to mine—Capable management and working plan—Power of personal touch.

FROM time to time, in *Coal Age*, different writers have referred to the effect produced by a few kind words and expressions of appreciation on the part of the management, in the daily operation of a mine. I have been deeply impressed with the same thought which conforms to my own observation.

A few months ago, I visited a mine that had always enjoyed a wonderful accident record. No fatalities had been reported from that mine for many years. Whenever a visitor alluded to that fact, the old boss would simply answer that he only employed experienced workmen. That he claimed would account for the absence of fatal accidents in the operation of the mine.

It always seemed to me that another factor has played a part in reducing the accident rating in that mine. However, there is now an opportunity of testing the truth or accuracy of the claim set forth by the foreman. Some time ago, the mine experienced a long strike and was finally compelled to resume operations with workmen having little or no mining experience and training.

Seven months have since passed and the results seem to prove that my surmise was correct. The records still show that they have been able to operate without special injury to any of their employees. The natural conclusion is that, as I had thought, there was something in the management of the mine that was more responsible for the safety of the workmen employed, than the experience and training of the men themselves.

Turning the matter over in my own mind, I have been asking myself, Why do accidents continue to occur at some mines and not at others working the same seam and under similar natural conditions? My conclusion is, there are two responsible factors—capable management and the adoption of a proper working plan.

Just here, let me make an allusion that, at first may not seem to be relevant. We hear of horse races being won owing to the peculiar ability of the jockey to keep in touch with the animal he rides and to whisper the proper word of encouragement when the horse's best efforts are needed.

Turning now from the jockey to the mine management, I have wondered if there is not such a thing as "touch," in the handling of difficult situations, when the best efforts of mine workers are needed. It is my belief that the speaking of the right word at the right moment has often won the day in mine management.

An instance that comes to my mind just now is one in which the management of a large corporation is of the most unassuming brand with which I have ever come in contact. The quiet consideration of all matters would appear to be the most noticeable characteristic. This feature is so sadly lacking in other large mining operations that in the case mentioned, it attracted my attention most forcibly.

Frequent visits to the place showed me that extra efforts were being made, at no small expense, to insure discipline. Believing that a bad practice once started was hard to stop, the management had placed in the hands of every employee a copy of the company's rules.

Special attention was given to see that each worker became familiar with the general plan of operations, and his efforts were carefully supervised and his work inspected to see that he complied fully with the regulations and practice of the company.

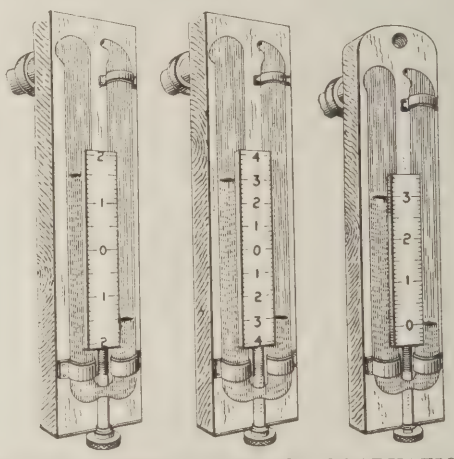
In all my experience, which includes five years in the coke regions of Pennsylvania, I have never seen better timbering of the working places and better roads, or a more thorough distribution of supplies than was observable in that mine. Evidently, the management was in close touch with the situation in every branch of the work. As a result, there was no confusion and everything moved smoothly and quietly.

Pikeville, Ky. GEORGE EDWARDS.

Inquiries Of General Interest

Reading Water Gages in Mines

Three Types of Water Gages—Differ Only in Graduation of Scale — Purpose of Water-Gage Readings in Mining Practice



RECENTLY we have been having considerable trouble in obtaining a satisfactory reading of the water gage in our mine. The gage is quite different from the one I have been accustomed to use in other mines. The general form of the gage is the same as other gages that I have used, consisting of a bent glass tube mounted on a wooden frame and having a scale graduated in inches.

The attempt to read this scale in our mine caused some dispute, which we have been unable to settle. I want to ask, If the water level is down one inch in the intake arm and up one inch in the return arm of the gage, does not this make a reading of two inches of water gage? But the scale on our instrument does not read two inches.

In my opinion, the measurement between the two water levels, taken with an inch rule, should show the correct water-gage reading. What puzzles me, however, is the fact that the scale does not read but half this amount, either at the upper or the lower level. Kindly explain where the trobule lies and how this scale must be read? FOREMAN.

McDonald, Pa.

There are three types of water-gage scales. As shown in the accompanying figure, two of these scales have the zero at the center and read both up and down. The third type, shown on the right of the figure, is by far the more common one in use. This scale has the zero at

SHOWING THREE STYLES OF GRADUATIONS

the bottom and reads upward, being graduated in full-length inches. The inconvenience of this scale is the fact that it must be set after the water gage is in position. By means of the adjusting screw, the zero of the scale is brought to correspond with the lower level. The reading of the upper water level is then the correct reading of the gage.

NO ADJUSTMENT AFTER GAGE IS IN POSITION

The advantage of having the zero in the center of the scale, as shown in the two gages on the left of the figure, is that no adjustment is needed after placing the water gage in position. Before doing so, however, it is important to adjust the scale so that its zero corresponds with the water level in both arms of the gage.

The scale on the left of the figure, like that on the right, is graduated in full-length inches. Therefore, in reading this scale, it is necessary to take the sum of the two readings or twice the reading at the upper or the lower level. These two readings should correspond, if the scale has been rightly adjusted before being placed in position, as the fall of the water level in the intake arm is always equal to the rise in the return arm of the gage.

Now, in order to overcome the necessity of taking the sum of the two readings or twice either of them, the scale shown in the center of the figure is graduated in half-length inches, so that the reading at either the upper or the lower level is the true reading of the gage. Many prefer this form of scale as being the most convenient for use in practice. There are some, however, who prefer the scale shown on the right, as giving the exact measurement between the two water levels, in inches. All of the scales shown in the figure read three inches of water column.

Examination Questions Answered

Mine Foremen's Examination Lexington, Ky., 1922

(Selected Questions)

QUESTION—*Butt entries are turned off to the right and left of the main heading every 300 ft. Assuming a block of coal 2,000 ft. long and 300 ft. wide, the height of the seam being 4 ft. and the coal having a specific gravity or weight of 80 lb. per cu.ft.; if it is necessary to take down 2 ft. of top on all entries, at a cost of $2 per yard, what will be the cost per ton-yard to extract this entire block of coal?*

ANSWER—Assuming the main headings are driven three abreast, 10 ft. wide and extend the entire length of the block, while the cross-entries are driven in pairs, there will be 2,000 yd. of top to be taken down in these three headings. Deducting 30 ft. for the combined width of the headings leaves a total of 270 ft. or 90 yd., for each double pair of cross-entries turned right and left from the main heading. We will assume five double pairs of butts or cross-entries. Each double pair will require $2 \times 90 = 180$ yd. of top to be taken down; or $5 \times 180 = 900$ yd. of top on the cross-entries, making a total of 2,900 yd. of top on the main headings and butts. At $2 a yard, the taking down of top will be $2 \times 2{,}900 = \$5{,}800$. Again, assuming a 90 per cent extraction of the coal, in this block 4 ft. thick and 2,000x300 ft. in section, the coal weighing 80 lb. per cu.ft., gives a tonnage of $0.90 \times 80(4 \times 300 \times 2{,}000) \div 2{,}000 = 86{,}400$ tons. We understand this question as asking for the cost of yardage, in taking down topping, per ton of coal mined, which is $5{,}800 \div 86{,}400 = 0.067$, or 6.7 cents per ton of coal mined.

QUESTION—*What is the weight of 100 cu.ft. of air, at a temperature of 60 deg. F., the barometer being 30 inches?*

ANSWER—The weight of dry air, at a given temperature and barometric pressure, is calculated thus

$$W = 100\,\frac{1{,}3273 \times 30}{460 + 60} = 7.65\ lb.$$

QUESTION—*A five-inch pipe line on a slope of 45 deg., has a length of 480 ft. and is full of water. How many gallons of water is in the pipe?*

ANSWER—Assuming the diameter of the pipe is 5 in., its sectional area is $0.7854 \times 5^2 = 19.635$ sq.in. Then, since the volume of a gallon is 231 cu.in., the number of gallons in this pipe, 480 ft. long, is $(480 \times 12 \times 19.635) \div 231 = 489.6$ gal.

QUESTION—*The ventilator produces 60,000 cu.ft. of air per minute in a mine, what volume of air would you expect to find at the working face, and how many men would you employ to conform with the law?*

ANSWER—Assuming the stoppings were well built and the air current divided so as to properly distribute the air in each section of the mine, the volume of air reaching the working faces should not fall below, say 55,000 cu.ft. per min. With this volume of air sweeping the working faces and allowing 100 cu.ft. of air, per man, per minute, to comply with the state mining law, the number of men employed may be 550.

QUESTION—*What special attention should a mine foreman give in the drawing of room and entry pillars?*

ANSWER—For this work, the foreman should employ only experienced miners. Before starting the work in any particular section of the mine, he should study carefully the conditions in respect to possible damage on the surface, inflow of water into the mine and the probable effect produced on adjoining workings. No pillars should be withdrawn until all the coal to be reached in that section has been taken out. The line of pillarwork should be kept as straight as possible, in order to avoid excessive roof pressure on the ends of any one of the pillars. It is important to see that the miners are kept supplied with what timber is needed to make them safe. The work should be carefully supervised by the foreman and his assistant and the falls should be examined daily for gas.

QUESTION—*What maps should be kept at the mine? What data should be shown thereon and how often should an extension be made on said map? If the map is drawn to a scale of 100 ft. per inch and the main heading, as measured on the map is 6 ft., what is the length of the entry in the mine?*

ANSWER—There should be kept at the mine, an accurate map showing the general plan and extent of the workings, together with the buildings and natural features on the surface and the boundary lines of the property. The elevation of many important points on the surface and in the mine should be marked on the map, which should also show the position of any drill-holes, giving the depth of hole and the thickness of coal in each. The map should be extended twice a year, by making an extension survey in the mine and marking this on the map, giving the date of the survey and the thickness of the coal at the working faces and at different points in the mine.

The scale of the map being 100 ft. per inch, a map measurement of 6 ft. would represent an actual distance of $100 \times 6 \times 12 = 7{,}200$ ft. of entry in the mine.

QUESTION—*What precautions would you adopt to reduce to a minimum the production and distribution of coal dust in a mine?*

ANSWER—In the first place, if the coal is blasted, only permissible explosives should be used, taking due care that the limit of charge is not exceeded in any one shot. Every shot should be carefully inspected by a competent person appointed for that purpose. A better plan is to have all holes drilled by the miners examined, charged and fired by shotfirers after the men have left the mine. Shotfirers should be authorized to refuse to fire any shot that, in their judgment, is unsafe. All fine coal and dust should be loaded out in dustproof cars and no accumulations of dust allowed at the working face. Strict rules and regulations should be adopted and enforced with suitable penalties, in respect to blasting, defining the kind and weight of powder to be used and the tamping of the holes.

QUESTION—*What points in a hoisting plant should be examined and how often, to insure yourself they are in a safe condition, in shaft openings?*

ANSWER—All hoisting equipment, including ropes, couplings, sheaves, brakes, winding drums and engines should be examined carefully, each day, by a reliable man appointed for that purpose and who should make any needed repairs that have to be made.

Resigning from Nationalization Committee Brophy Charges Lewis with Evasion

John Brophy resigned as chairman of the Nationalization Research Committee of the United Mine Workers of America, in a letter to President John L. Lewis, dated Feb. 5. In his letter of resignation Brophy demands that Lewis come out openly for nationalization of the coal mines, appear before the U. S. Coal commission and in public during the next eleven months and speak for nationalization before the miners and open up the columns of the *United Mine Workers' Journal* to a discussion of the question.

Mr. Brophy's resignation comes two weeks after that of C. J. Golden, who retired from the Nationalization Committee when Ellis Searles, editor of the *Mine Workers' Journal,* in a statement said that the Nationalization Committee's report was inspired by a radical element in New York and had not been officially adopted by the miners' convention. Brophy's letter follows:

"I submit my resignation as chairman of the Nationalization Research Committee of the United Mine Workers of America. We have done our job. We have drawn up a concrete plan for nationalizing coal.

"Recent events have made plain to you and me as to every other miner that nationalization is the master current of the United Mine Workers of America. The tide gathers volume and will sweep irresistibly into the next International Miners' Convention in January, 1924. Who is the King Canute that will sit on the beach and tell the tide to quit rising? It will splash him and float away his chair of office. The miners are feeling the power of an idea, and they see the driving force of a detailed plan.

"The International Miners' Convention of 1921, and you, as president, outlined the duties of our committee. You bade us familiarize ourselves with the problem by 'consulting with authorities'; you asked us to formulate a 'detailed practical policy to bring about the nationalization of the coal mines.' And you ordered us to 'aid in the dissemination of information among our members and the public.'

"We could not better your instructions, because they are all inclusive. But we fulfilled them with results that surpassed our hopes. We consulted miners, labor men in other industries, economists, statisticians, government officials, lawyers, administrators, technicians, engineers—every type of expert opinion. In accordance with your order we drew up the plan as the result of this prolonged investigation. The only other ways of making the plan would have been to let it drop into our mind as a perfect abstraction from a timeless world, or else to turn over the job to some group of professional liberals and let them project a theory.

"We did neither. We preferred the method of hard work and expert advice. We have presented the American plan for nationalizing coal in a pamphlet, 'How to Run Coal,' in which every detail is hammered home and the full union strength and bargaining power of the United Mine Workers of America are maintained and safeguarded for all time. Your committee challenges critics of the plan to point out a weak place. The only possible opponents of the plan are those who are opposed to the principle of nationalization. All such opposition we desire to locate and to face in the open. We offer the American plan for nationalization as the only adequate solution for the present chaos of coal. We submit that in it we have met your conception of our duties.

"As to the disseminating information 'among our members and the public,' we have obeyed your orders. The miners' American plan for nationalization has been published in newspapers throughout the country. Editorial comment is almost universal. Every prominent union official is being flooded with inquiries.

"The time has come for a united front and a spirited advance. Will you as a leader give us the lead?

"Will you throw open the *Mine Workers' Journal* to our plan? The newspapers of the country are willing to devote columns to our findings, but our own official organ refuses to carry a paragraph. The editor, Ellis Searles, attempts to discredit our efforts by using a 'Red' herring. Our plan was not 'in part prepared for the committee by some well-known New York radicals.' They would be the last to claim any connection with the matter under discussion, because the facts reveal their innocence. To permit outside organizations to butt into labor policy is the destruction of trade unionism. The methods of the Nationalization Research Committee, in preparing a case, have been the same as your own methods—no recognition of outside organizations in union affairs, consultation with individual experts on details, a trade union decision on policy.

"Will you mail copies of the American plan to the 600,000 union miners? If the plan does not embody their aspirations in concrete form this test will kill it. Replies we have received from miners in every coal district of the United States show that the plan is the answer to their unrest and the rallying point for the larger policy of the union.

"Will you urge upon the officials of the twenty-six districts of the United Mine Workers of America a powerful intensive campaign of education, district by district, in support of nationalization?

"Will you appear before the coal industry Fact-Finding Commission in support of the miners' nationalization plan?

"Will you take the platform in behalf of nationalization in miners' meetings and public meetings, through these next crucial eleven months?

"Will you aid in drawing up a bill for nationalization, to be presented at the next international convention? We can promise you support from the rank and file, and an overwhelmingly favorable vote.

"These are six important next steps in the miners' program. The coal operators are discredited and defeated in the court of public opinion. The public is disgusted by the overdevelopment, mismanagement and waste of the coal industry, and is ready for a large-scale solution.

"The miners are determined. The movement waits on you. But it will not wait long for any leader. It will create its own leaders.

"Hampered by the silence of the *Mine Workers' Journal* and by the lack of hearty official support, our Nationalization Research Committee hereby appeals directly to the rank and file. We have done the work you ordered, but we have not received the support you promised. We shall continue to carry on the work outlined in the American plan. We shall demand speeding up the campaign for nationalization in the ways specified in this letter. We enter the last stages of this fight, which will end victoriously in the International convention not as a committee but as miners representing the rank and file.

"So I submit my resignation as chairman of the Nationalization Research Committee. And I urge you, as International president, to aid the miners in their American plan."

Sees Opportunity for Big Work by I. C. C. In Assigned Car Case

An opportunity to do big, constructive work is presented to the Interstate Commerce Commission in the assigned-car case, it is declared by attorneys for the Southern Ohio Coal Exchange, in a brief which they have submitted to the commission. In their proposed rules the carriers, says this brief, have assumed that because the commission has recognized their need for a fuel supply, they can obtain that supply regardless of the manner in which it is transported. A paragraph from the brief reads as follows:

"Constantly recurring miners' strikes arising from insistent demands for higher wage returns; the yearly runaway coal markets arising from fear of inadequate coal supply, or inability to transport the product, are matters that vitally concern the public. The outstanding cause for this unrest and uncertainty in the coal business is the preference that is given certain operators through the assigned car as now used by the railroads. That cause the commission has power to correct. Having the power, we respectfully and earnestly insist that we have shown that there is need for its exercise if the conditions that annually vex the coal business of the country are to be changed for the better, and the recurring agitation and unrest ended."

New York Wholesalers Seek Reduction of Freight Rates to Tidewater

Efforts are being made to enlist the members of the Wholesale Coal Trade Association of New York, Inc., in a movement the purpose of which is to present arguments to the Interstate Commerce Commission in favor of a reduction of freight rates to tidewater, reducing or abolishing the "trimming charge" and to recover from the railroads the difference between what should have been charged under the increases authorized and the higher rates which were put into effect, as well as recovering the "trimming charge."

The circulars have been mailed to all members of the association by Charles S. Allen, its former secretary, explaining the purpose of the movement. In his report to the Board of Directors of the association Mr. Allen says that in 1918 the Railroad Administration by its General Order No. 18 advanced the rates on practically all commodities 25 per cent, but saw fit to discriminate in the adjustment of rates on tidewater coal in such a manner that the increase amounted to about 28½ per cent as follows:

	Original Rate	28½ Per Cent Increase	25 Per Cent Increase	Overcharge
Clearfield	$1.65	$2.15	$2.09	$0.06
Greensburg	1.75	2.25	2.19	0.06
Westmoreland	1.90	2.40	2.34	0.06
Pittsburgh	2.05	2.55	2.49	0.06

In 1920 by ex parte 74, the Interstate Commerce Commission granted an increase of 40 per cent, says Mr. Allen, and in applying the 40 per cent increase, but not in the manner directed by the commission, there was produced a set of rates which returned an increase of 43.6 per cent on the then improper rates in the $2.15 scale, as follows:

	Base Rate	43.6 Per Cent Increase	40 Per Cent Increase	Overcharge
Clearfield	$2.15	$3.11	$3.05	$0.06
Greensburg	2.25	3.21	3.15	0.06
Westmoreland	2.40	3.36	3.30	0.06
Pittsburgh	2.55	3.51	3.45	0.06

Mr. Allen contends that the association can successfully establish before the commission that the scale of rates beginning with $2.15 from the Clearfield region was an improper basis for the 40-per cent increase, but that the scale beginning with $2.09 should have been used, in which case rates would have been produced as follows:

	Base Rate	40 Per Cent Increase	Rates as Published	Overcharge
Clearfield	$2.09	$2.97	$3.11	$0.14
Greensburg	2.19	3.07	3.21	0.14
Westmoreland	2.34	3.22	3.36	0.14
Pittsburgh	2.49	3.37	3.51	0.14

The claim also is made that under the order issued by the I. C. C. in 1922 and popularly referred to as a 10-per cent reduction in rates, the order really provided that where the previous order had authorized an increase of 40 per cent that increase should be reduced to 26 per cent. The figures produced by that order are as follows:

	Base Rate	26 Per Cent Increase	Rates as Published	Overcharge
Clearfield	$2.15	$2.73	$2.74	$0.01
Greensburg	2.25	2.83	2.84	0.01
Westmoreland	2.40	2.98	2.99	0.01
Pittsburgh	2.55	3.13	3.14	0.01

With respect to the 40-per cent increase, Mr. Allen contends that the proper base rate should have been the $2.09 Clearfield scale, producing figures as follows:

	Base Rate	26 Per Cent Increase	Rates as Published	Overcharge
Clearfield	$2.09	$2.66	$2.74	$0.08
Greensburg	2.19	2.76	2.84	0.08
Westmoreland	2.34	2.91	2.99	0.08
Pittsburgh	2.49	3.06	3.14	0.08

In referring as to how the new rates were arrived at, Mr. Allen says it is significant that in the application of the 25 per cent (28½ per cent) increase, in 1918, the carriers used the Pittsburgh rate as the basis; that in 1920, when the 40 per cent (43.6 per cent) increase was made, the Westmoreland rate was used; and, in 1922, when the so-called reduction of 10 per cent (26 per cent increase) was made, the Greensburg rate was used as the base, the rates from the other regions being arrived at in each instance by either adding or deducting the previously fixed differentials.

The present rate, he says, beginning at $2.74, are 8c. per ton more than they should be. Add to that the unwarranted "trimming" charge of from 3c. to 8c. per ton, and shippers using these rates are now compelled to overcome a disadvantage of at least 11c. per ton.

Taking the most unfavorable aspect of the case, namely, that the commission will not agree to the contention that the base rate for the 40-per cent increase should have been the scale beginning with $2.09, but rather should have been that beginning with $2.15, shippers would be entitled to a refund of 6c. per ton, plus the trimming charge.

Lehigh Valley Files New Segregation Plan

The modified plan for the segregation of the coal and railroad properties of the Lehigh Valley Railroad Co., as ordered by the United States Government, was on Feb. 7 filed in the District Court of the United States, Southern District of New York. Hearings on the plan will, it was said, be held some time after Feb. 15.

The plan was filed through E. H. Boles, counsel for the railroad company, and other signatures are F. W. Wheaton, counsel for Lehigh Valley Coal Co. and Coxe Brothers & Co., Inc., and George W. Field, counsel for Lehigh Valley Coal Sales Co.

Although the modified plan was changed in several particulars from the original one, there is a likelihood that further minor changes will be made in view of the fact that Attorney General Daugherty stated a month ago that while the revised draft was in the main satisfactory, he would offer to the court a few "wholesome suggestions."

The plan provides that its stockholders shall have the right to subscribe for certificates of interest in the ownership of the Lehigh Valley Coal Co. at the rate of $1 per share, on the basis of one certificate, equivalent to one share of no par value, for each share of railroad stock owned.

Capital stock of the coal company at present is pledged under the railroad company's general consolidated mortgage and on that account it is necessary to distribute certificates of interest instead of actual shares of stock, but these certificates will carry full voting powers, dividend rights, etc. Upon the termination of the mortgage actual shares will be issued for the certificates.

To meet the government's requirements, it is proposed that subscribers for the coal company certificates will agree to dispose of these certificates, if they continue to hold railroad stock, by Dec. 31, 1927. Dividends are to be withheld by the coal company until stockholders have disposed of either their coal shares or their railroad shares. Subscribers to the coal company certificates will not be permitted prior to Dec. 31, 1927, to increase their holdings in either company until they have disposed of their ownership in the other.

To compensate the railroad company for advances made the coal company for capital expenditures, etc., in the past, the coal company will sell $15 000 000 in bonds of a new $40,000,000 issue. Part of the balance of the issue will be used to retire outstanding bonds maturing in 1933, and the rest, estimated at approximately $18,500 000, will be available for improvements by the coal company when occasion demands.

Stock of Coxe Brothers & Co., Inc., pledged under the railroad company's collateral trust agreement, maturing in 1926, in view of the proximity of this date, is undisturbed under the plan, except that the voting power is assigned to a trustee, to be appointed by the district court. A similar arrangement is offered with regard to the stock of the Delaware, Susquehanna & Schuylkill Railroad Co., pledged under the same agreement. The Lehigh Valley, in the meanwhile, will ask the Interstate Commerce Commission for authority to merge this line in accordance with the Interstate Commerce Act.

Bituminous Output Lower Since Jan. 1, But Is in Excess of Consumption

Since the first week in January, according to the report of coal stocks as of Jan. 1 undertaken by the Bureau of the Census and the U. S. Geological Survey, under authority of the Federal Fuel Distributor, the trend in the rate of bituminous coal production has been downward, but the total output during the month was in excess of consumption and stocks increased. Stocks on the Lake docks on Jan. 1, classed as coal in transit, were 3,129,206 tons. Reports from a group of producers indicate that there were nearly 750,000 tons in storage at the mines or at points between the mines and ultimate destinations.

Retail coal dealers' stocks of anthracite on Jan. 1 were considerably more than on Oct. 1, but were less than on any

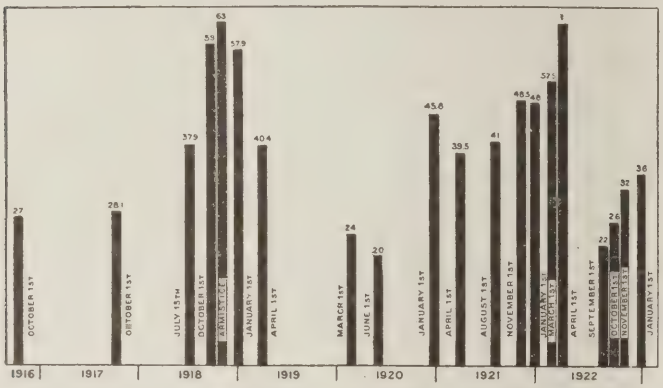


FIG. 1—TOTAL COMMERCIAL STOCKS OF BITUMINOUS COAL, OCT. 1, 1916, TO JAN. 1, 1923

Figures represent million net tons and include coal in hands of railroads, industrial consumers, public utilities and retailers. Coal for steamship fuel, on Lake docks, and in transit is not included. Figures for 1922 and 1923 are subject to revision.

corresponding date for which records exist. Stocks of anthracite on the Lake docks were but 13 per cent of those on Jan. 1, 1922.

ESTIMATED TOTAL COMMERCIAL STOCKS OF BITUMINOUS COAL
(Net Tons)

Oct.	1, 1916	27,000,000	April	1, 1921	39,500,000
Oct.	1, 1917	28,100,000	Aug.	1, 1921	41,100,000
July	15, 1918	39,700,000	Nov.	1, 1921	48,500,000
Oct.	1, 1918	59,000,000	Jan.	1, 1922	48,000,000*b*
Day of Armistice		63,000,000	March	1, 1922	52,500,000*b*
Jan.	1, 1919	57,900,000	April	1, 1922, at least	63,000,000*bc*
April	1, 1919	40,400,000	Sept.	1, 1922	22,000,000*b*
March	1, 1920	24,000,000	Oct.	1, 1922	26,000,000*bd*
June	1, 1920	20,000,000	Nov.	1, 1922	32,000,000*b*
Jan.	1, 1921	45,800,000	Jan.	1, 1923	36,000,000*b*

a The figures for 1918 in this table are based upon an actual count. Beginning April 1, 1919, the figures are estimates based upon reports from a selected list of 5,000 consumers whose stocks in 1918 bore a known relation to the known total stocks.

b Subject to revision.

c No canvass of consumers was made on this date. The total stock was estimated from the stock on March 1, ascertained by questionnaire.

d Revised from last report.

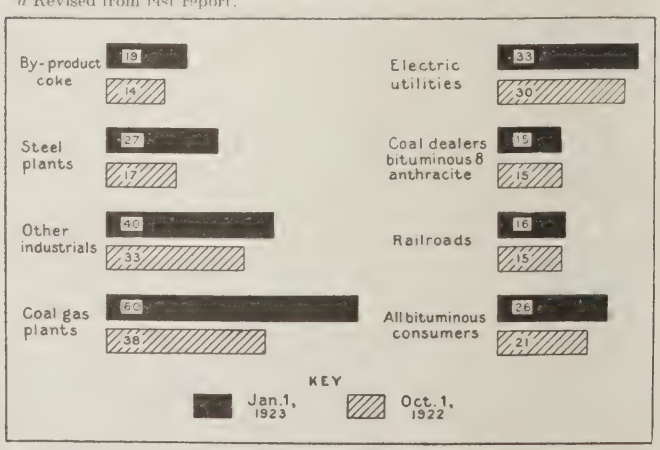

FIG. 2—DAYS' SUPPLY HELD BY DIFFERENT CLASSES OF CONSUMERS ON JAN. 1, 1923 AND OCT. 1, 1922

At the rate coal was being burned in November and Deecmber, 1922, the stock of soft coal on Jan. 1, 1923, were sufficient to last 26 days. On Oct. 1, 1922, the stocks were sufficient to last 21 days and on June 1, 1920—when stocks were at the lowest point on record—they were sufficient for only 15 days. There are indications that stocks have continued to increase since Jan. 1.

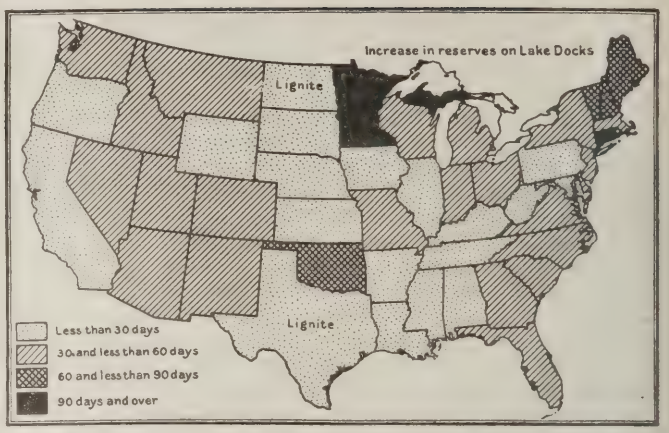

FIG. 3—DAYS' SUPPLY OF SOFT COAL ON HAND AT INDUSTRIAL PLANTS ON JAN. 1, 1923

At the rate of consumption prevailing in November and December, stocks at industrial plants other than steel and by-product coke would last on the average 40 days. How the supply varied from state to state is shown in the diagram. The darker the shading the heavier were the stocks. Any change in business activity affecting coal consumption would be reflected in the days' supply. Based on reports from 2,265 plants.

From Fig. 1, it is seen that coal flowed into storage much more rapidly during October than at any time since the ending of the miners' strike. During that month stocks increased at the rate of 194,000 tons per calendar day against 66,000 tons in November and December.

Fig. 2 and the table below show consumers' stocks in terms

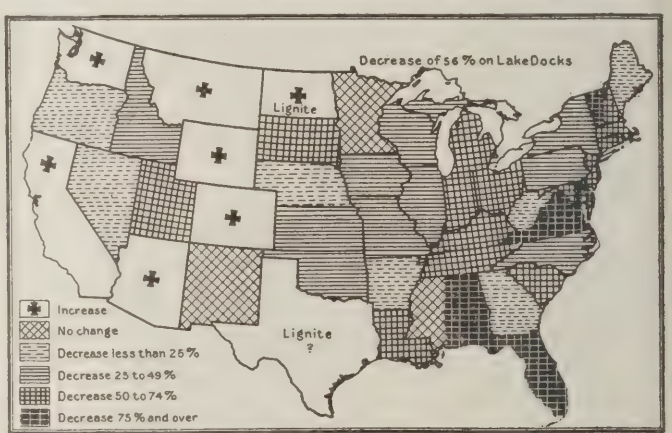

FIG. 4—HOW RETAILERS' STOCKS OF ALL COAL—ANTHRACITE AND BITUMINOUS—ON JAN. 1, 1923, COMPARED WITH THOSE ON JAN. 1, 1922

Stocks of bituminous coal in retail yards on Jan. 1 were approximately three quarters what they were a year ago. Stocks of anthracite were not quite 30 per cent of last year's stocks. The total stocks of retailers—including both hard and soft coal—showed a decrease of 52 per cent when compared with 1922. The map shows that many of the Western States had larger stocks and that the decrease was most accute in the territory east of the Mississippi.

of days' supply, based upon reports of tons on hand and actual consumption received from about 5,000 consumers, so selected as to be fairly representative of all commercial consumers.

DAYS' SUPPLY OF BITUMINOUS COAL IN HANDS OF VARIOUS CLASSES OF CONSUMERS, NOV. 11, 1918, TO JAN. 1, 1923

(Figures represent number of days supply would last at current rate of consumption at time of stock-taking.)

	Nov. 11, 1918	Jan. 1, 1919	Mar. 1, 1920	June 1, 1920	Jan. 1, 1921	Apr. 1, 1921	Jan. 1, 1922	Mar. 1, 1922	Sept. 1, 1922	Oct. 1, 1922	Nov. 1*b*, 1922	Jan. 1*b*, 1922
Byproduct coke plants	35	32	15	8	29	28	42	39	11	14	18	19
Steel plants	45	42	9	11	42	38	48	48	12	17	21	27
Other industrials	71	65	27	24	64	47	51	56	32	33	39	40
Coal gas plants	85	81	31	22	55	66	89	82	34*a*	38*a*	55	60
Electric utilities	49	49	21	22	44	48	51	54	26*a*	30*a*	32	33
Coal dealers, bituminous	37	39	13	10	30	26	33	23	11	18	21	18
Railroads	31	32	11	10	23	24	35	42	13	15	13	16
Total bituminous	45	42	18	15	39	36	41*a*	43*a*	17*a*	21*a*	23*a*	26*a*

a Estimated from incomplete data. Subject to revision.

b See text for rate of consumption at which these figures are calculated.

Work of U. S. Coal Commission Handicapped by Dilatory Tactics of Congress

By Paul Wooton
Washington Correspondent of *Coal Age*

Washington, Feb. 13.—The vacancy on the Coal Commission caused by the resignation of Judge Alschuler probably will not be filled, it was announced at the White House this morning. It is understood that the President conferred with members of the Coal Commission and reached the conclusion that it would be inadvisable to go to the trouble of appointing a new man with so much of the work already done. Attention was called at the White House to the fact that it was not obligatory to have seven men on the Coal Commission, the resolution providing that the membership shall not exceed seven.

Congress, in characteristic fashion, has failed lamentably to hold up the hands of the Coal Commission which it created. Because of its dilatoriness, the services of Judge Alschuler, one of the commission's most valuable members, were lost. Early in its term the commission asked also for legislation to make compulsory and provide penalties covering the returns submitted on questionnaires. As this is written there still is much uncertainty as to when that legislation will be forthcoming. It still remains to be seen whether or not the same dilatory policy will prevail in the handling of the legislation carrying $400,000 for the commission's expenses.

The procrastination and the lack of interest on the part of Congress is handicapping the commission in its work and lessening its possibilities for usefulness. The attitude of the legislative bodies toward the Coal Commission cannot be attributed to any displeasure with the work the commission has done. On the contrary, opinion on Capitol Hill is generally favorable to the commission. The personnel of the commission is universally admitted to be strong. Most certainly there has been no unfriendly sentiment against Judge Alschuler.

Consistent Legislative Policy Lacking

The failure to uphold the hands of the commission is simply another indication of the lack of consistency in carrying forward legislative policies. When the commission bill was passed the country was face to face with an emergency with coal. Public opinion was inflamed. Under those conditions Congress was prompt to pass the bill and apply the counter-irritant. In the meantime the emergency has passed. The strike danger has been postponed for a year. The price of coal is falling and the full requirements of the country are in a fair way to be met. Public interest no longer is focussed on coal. As a result the legislation held to be necessary to the commission's maximum accomplishment goes over from day to day and week to week. Even Chairman Winslow, of the Committee on Interstate and Foreign Commerce, coming as he does from New England, where the fuel situation has been most acute, ranks the coal bill as eighth in importnace among the measures that his committee will bring before the House. When his committee has its day, under House rules, seven other pieces of legislation must be disposed of before the coal bill is laid before the House.

During the conference with Washington correspondents, on Feb. 10, Chairman Hammond was asked if there is any truth in the report that he would finance some of the commission's activities in case Congress should fail to provide additional funds. This amused Mr. Hammond greatly. The question reminded him, he said, of the case of the Mexican peon who struck a bonanza and acquired such a reputation for wealth and generosity that he is said to have contemplated the payment of the Mexican national debt. The bononza ran out, however, and it finally became established that Don Pedro was in no position to live up to his reputation.

It was announced at the conference that the commission would give consideration to the proposed legislation perscribing standards of quality for anthracite. The commission's program of precedure is not as yet in final form, it was stated.

The stock report, issued under the authority of the Federal Fuel Distributor, showing only 36,000,000 tons of coal in storage on Jan. 1, reveals how unprepared the country would have been to withstand a strike this year. With stocks at that level and with demand much increased over that of a year ago, it is apparent that the country could not have built up stocks to equal those of April 1, 1922, when 63,000,000 tons was in storage. The stock report explains clearly why prices are 50 per cent higher than they were a year ago.

Slack Retires by Request; Conspiracy Case Shows No Sign of Life

Word received in Indianapolis from the Department of Justice in Washington, D. C., substantiates rumors of a week concerning the retirement of L. Ert Slack, of Indianapolis, who has seen service as a special assistant attorney general of the United States in charge of what has become known as the government's coal conspiracy case. It was said Mr. Slack had resigned at the request of the Attorney General. The request for the resignation was sent last month and Mr. Slack ceased to be a government official Jan. 31. He was ordered to turn over all records and papers in the cases to Homer Elliott, U. S. Attorney for Indiana. Denial was made at the Department of Justice that any significance was to be attached to Mr. Slack's retirement. It was ordered, it is said, in the interest of economy. The work, it was said, could be handled without extra cost by the U. S. Attorney for the district.

Soon it will be two years since 226 operators, miners and corporations were indicted in the District Court for violation of the Sherman Anti-Trust Law. Mr. Slack was U. S. Attorney before he became a special assistant attorney general.

Ford Organizes $15,000,000 Coal Company

The Fordson Coal Co. was incorporated at Dover, Del., Feb. 9 with a capitalization of $15,000,000, to operate coal properties purchased by Henry Ford in Kentucky and West Virginia.

The organization of the coal company may result, it was said, in Mr. Ford selling coal to the public. This depends upon the quantity of fuel produced and the requirements of the Ford plants. The Ford Motor Co. has for some time been selling fuel to its employees in Detroit at prices considerably lower than those asked by retailers, the present price for bituminous being $8.50 a ton.

Statements by Mr. Ford during the recent mine strike indicated that the public might expect a cut rate if the Ford fields yield a surplus. During the strike Mr. Ford attacked the retailers as well as the operators and mine union chiefs, declaring that a conspiracy existed for the purpose of retarding production and inflating prices. Coal could be sold at a profit to all handlers, he said, at prices considerably lower than were then demanded.

Since the transfer of the Pond Creek company to the Ford interests, on Jan. 1, the mines have been operated temporarily by the Banner Port Coal Co., a Ford subsidiary.

The charter filed at the State Department in Dover for the Fordson Coal Co. includes among the incorporators Douglas Brown, of Huntington, W. Va.

Enjoins Union from Organizing in Logan

Judge Robert Bland, in the Circuit Court at Logan, W. Va., on Feb. 10 granted two identical injunctions forbidding officers or members of the United Mine Workers from compelling or persuading miners in Logan County to break the individual contracts under which the Logan coal field is kept in a non-union status. The injunctions were granted in separate but similar equity cases, one brought by a score or more of miners who declared they were suing not only for themselves but for the other non-union miners of the county, and the other by the non-union coal companies in the county, making up the Logan Coal Operators' Association.

After presenting the two petitions, A. M. Belcher, counsel for the plaintiffs, told the court that 95 per cent of the mines in Logan County had written contracts with their employees by which they agreed not to become affiliated with the United Mine Workers and the operators agreed not to employ union men. C. Frank Keeney, president of District No. 17, United Mine Workers, in an address at Fairmont on Feb. 8, according to Mr. Belcher, declared the union was getting ready to organize Logan County.

C. J. Van Fleet, counsel for the union, told the court the defendants made no appearance and asked that any order entered in the case show that there was no appearance for the officials of the international district and local union who were named as defendants in the bill. He was in court, he said, to ask for bail for Jesse Covert, recently arrested on charges in connection with the armed march of 1921.

Phelan Resents Picturing of His Coal Bin

Publication of an article in a Boston newspaper criticising the state emergency fuel administrator, James J. Phelan, for the amount of coal held in the bins at his home for his personal use has led that official to issue a formal statement pointing out that he had in his bins on Feb. 8 five tons of buckwheat coal, one and one-half tons of furnace coal, one ton of range coal, and a cord of wood. He points out that the buckwheat coal was purchased as a substitute to use with the small amount of furnace coal which he had purchased last March.

Mr. Phelan denied that he "is a director of one of the largest soft-coal corporations in the country." He denies that he is a director of the New River Coal Co. and states that he has no interest, direct or indirect, in that or any other coal company. He does call attention to the fact that he is a director of the U. S. Smelting, Refining & Mining Co., which does own a coal mine in Utah, but since none of that coal is marketed in New England, he feels that this interest in no way could prejudice his administration of fuel matters in Massachusetts.

Alex Is Out Again—for a While

Alex Howat's monkey-and-parrot time of it with Kansas jails continues merrily on from laugh to laugh. Last week the deposed Kansas miners' union district president, languishing comfortably in the Cherokee County jail, was pardoned by his new friend Governor Jonathan Davis, recently elected. But since Alex wouldn't pay the court charges, the pardon didn't "take." So at the end of the week Alex was still languishing in the warmth of the donjon keep, enjoying good Kansas fodder and doing no work whatever. The Kansas Attorney General insists Howat should serve out his various and sundry jail sentences in both Cherokee and Crawford counties for defying the Kansas Court of Industrial Relations. At that time he still had 46 days coming to him in Cherokee County and 99 or so in Crawford County, from whose jail he was paroled by a Davis-appointed judge Jan. 20. The miners of District 14 raised $500 to pay the costs of prosecution, as demanded by the judge, and Howat was released Feb. 12.

Ruhr Occupation May Hasten Wind-Up of Rhenish-Westphalian Coal Syndicate

That the occupation of the Ruhr district has brought about a momentous phase in Germany's coal situation is evident when it is remembered that the Ruhr district contributed to the total German production of bituminous coal about 80 per cent and of the coke output 85 per cent. As the first consequence of the occupation the Rhenish-Westphalian Coal Syndicate, situated in Essen, has removed its headquarters and all records to Hamburg.

This move, which manifestly was caused by the desire to keep the syndicate out of the sphere of interference, was coupled with the decision to wind up the syndicate at the expiration of the term for which it was organized, March 31. In the latter respect the Ruhr occupation has most likely provided to the men of the syndicate a welcome opportunity. During recent years its members have given ample evidence that they regard the syndicate as an obsolete and superfluous institution. Almost at every occasion since the end of the war, the negotiations for its renewal have broken down and had it not been for the governmental pressure threatening to make the renewal compulsory, it would, no doubt, have come to an end at a much earlier date. By the process of trustification the membership of the syndicate has virtually if not actually dwindled to a small number.

The few men who actually control the coal production in the Ruhr district do not need a syndicate, having long ago established close relations of a more effective nature. Through the establishment of the National Coal Commissary, in whose hands the distribution of coal rests, and the formation of the National Coal Association, in which the Rhenish-Westphalian Syndicate is the leading member, it has lost a good deal of its former importance. As there is no competition among the producers and cannot be while the control of coal lasts and every ton finds a ready market, it has lost its original chief function. At present it is only a clearing house of sales and an important part in the mechanism of distribution. Other business it had is now mostly transacted outside of its realm among a small circle of men.

Sign Scale Agreements in Southwest

Scale committees of Districts 14, 21 and 25, in Kansas, Missouri, Oklahoma and Arkansas, signed an agreement at Kansas City Feb. 8 for one year from April 1 at $7.50 a day and a tonnage scale of $1.15 to $1.92. In a separate conference the Kansas district is trying to work out its first machine scale, made necessary by the steadily increasing number of machines.

Second Herrin Trial On; Choose Jurors

The second Herrin trial started on Monday, Feb. 12, at Marion, Ill. Nine men are to be tried for the murder of Antonio Mulkavitch, one of the twenty-two non-union strip miners and guards shot and cut to death June 22, last, after they had surrendered to a mob which besieged Lester Mine near Herrin, Ill. Three of the nine—Otis Clark, Peter Hiller and Bert Grace—were among the five acquitted last month at the first trial growing out of the massacre. The other six are Hugh Willis union board member; Dallas McCree, Oscar Howard, Percy Hall, Philip Fontanetta and the one indicted negro James Brown. All are union miners except Hiller. The first days of the case will be spent in picking jurors. Since the prosecution's single slender hope lies in a fearless and unbiased jury, much time may be consumed in challenging salesmen. The union lawyers resumed obstructing tactics by moving the indictment be quashed.

Globe Company to Be Western Agent for Pennsylvania Coal Company

Chicago, Feb. 13.—The Globe Coal Co., of Chicago, will soon take the full sales agency for the Pennsylvania Coal Co.'s anthracite, otherwise known as Erie coal, west of Pennsylvania. This will abolish the Williams & Peters sales agency in Chicago. The change is expected to take place April 1, but will in any event be in effect not later than Nov. 1. Harry N. Taylor, the new president of the United States Coal Corporation, has been elected president of the Sheridan (Wyo.) Coal Co., succeeding Peter Kooi.

New York and New England Insistent on Embargo of Anthracite to Canada; I.C.C. to Hold Hearing

New York officials have joined forces with New England in trying to force the administration at Washington to embargo anthracite shipments to Canada. In response to this pressure the Interstate Commerce Commission has instituted on its own motion an investigation into the question, citing in particular the Hudson Coal Co., which company, according to Fuel Distributor Wadleigh, will not disclose to him any information as to the destination of its shipments of hard coal. The Fuel Distributor has requested the Commerce Commission to obtain this information for him.

New York and New England officials are intent on denying to Canada the small exports of domestic anthracite alloted to it. New York Administrator Goethals and Governor Al Smith have telegraphed President Harding asking that the exports be cut off. Canada, it is reported, has retaliated by threatening to cut off water-generated electricity from the Canadian side of Niagara.

Calls Attention to Power Supplied by Canada

Mr. Wadleigh has asked General Goethals whether the addition of this 4 per cent to the coal supply for New York State would compensate for the electric power now obtained from the other side, equivalent to more than 1,000,000 tons of steam coal per year. Mr. Wadleigh's letter to General Goethals reads as follows:

"Disregarding any other factors involved, I would call attention to the fact that shipments of household sizes of anthracite coal to Canada are now proceeding at the rate of approximately 188,000 gross tons per month, amounting to 2.1 per cent of the total anthracite shipments, and this amount is necessary in order to maintain health and life among tenement dwellers in Canadian cities, while shipments of similar sizes into the State of New York, from the last weekly figures available, were at the rate of approximately 1,300,000 gross tons per month. The above figures do not include shipments by the Hudson Coal Co.

"Coincident with this New York State received April 1 to Dec. 31, 1922, from the Canadian side 778,738,740 electrical horsepower, which would require at least 1,062,988 tons of coal in its replacement.

"The delivery of coal to Canada is in accordance with an agreement by which Canada exports electricity equivalent to 2,000 tons of coal a day into New York."

On Feb. 10 Governor Smith of New York added his request to that of General Goethals, who wrote a few days before to Mr. Wadleigh calling for immediate action.

General Goethals drew a picture of the people of upper New York State, short of anthracite, conscientiously using coal substitutes, shivering and discouraged as they saw their schools and churches closed for lack of heat and yet compelled to watch from their windows train after train of coal speeding toward Canada.

"I found deep resentment as to this on the part of all I saw on my trip, and there is no doubt that it is causing the strongest feeling of discontent in the whole country," he wrote Mr. Wadleigh.

"In a speech made by Representative Rogers on Jan. 11, in the House of Representatives, attention is called to the fact that the shipments of coal to Canada in 1921 exceeded those of any previous year; that the shipments into Canada in October and November of 1922 exceeded shipments in the corresponding months of 1921," he continued. "This information has been broadcast through the press. From figures given us, and which I believe are reliable, of the total shipments by the Delaware & Hudson in 1921, 9 per cent went to Canada, while in 1922 11 per cent went to Canada. The statement is also made, and I believe it to be true, that shipments were rushed to Canada at the end of 1922 because of possible weather conditions that might exist early in the year 1923. These shipments are still being made to Canada, while the weather conditions in northern New York are more severe than they have been for years past.

"The severe weather in the last half of January and so far this month has materially curtailed railroad operations through the northern portion of the state. Cars are tied up at sidings and consignments to various localities in the northern part of the state are held without any idea as to when the cars will reach destination.

"As I stated before, definite action must be taken, and taken at once; and I recommend:

"(1) That in view of the conditions existing in 1922, as compared with 1921, the present allotment be exceeded so that sufficient anthracite coal will be moved without delay into this territory, which, combined with the substitutes that are required under the district order, will give the people in that part of the state the fuel they need.

"(2) That in order to accomplish this, the Delaware & Hudson Railroad Co. be required to supply anthracite coal along its route in the upper part of New York State in lieu of making any shipments into Canada.

"(3) That until this is done and until the situation in northern New York is relieved as above recommended, an embargo be placed on the Delaware & Hudson shipments into Canada."

To the request of Governor Smith that an embargo be declared on exports of anthracite, President Harding replied that his information is that the situation is one of transportation failure rather than shortage of supply. He expressed the belief that the situation would be relieved as a result of a conference between Mr. Wadleigh and the New York Fuel Distributor.

Press reports from Ottawa last week were to the effect that a grave situation would develop in Canada if an embargo on Canadian-bound coal were placed on the Delaware & Hudson R.R., in the opinion of C. A. Magrath, a member of the Dominion Advisory Fuel Committee.

This section, he continued, now faced conditions even more severe than those in New York State, because it was further from American mines and must weather a harder winter.

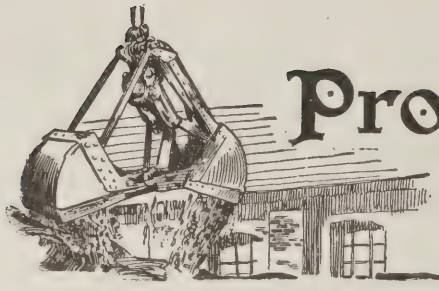
He said he did not believe in thinking, let alone saying, disagreeable things about neighbors nor in discussing reprisals.

The hearing of the Interstate Commerce Commission was to be held at the Bowling Green Building, 11 Broadway, New York City, on Wednesday, Feb. 14.

Lodge Resolution Urges Anthracite Embargo

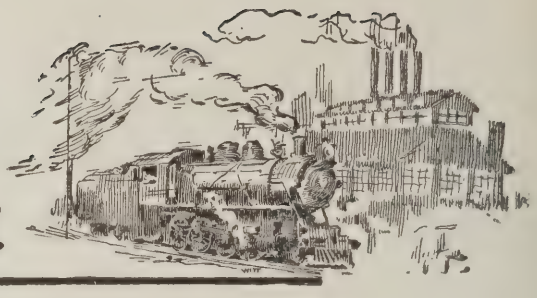
Senator Lodge has presented to the U. S. Senate the following resolutions adopted by the Massachusetts House of Representatives:

Whereas the Hon. John J. Rogers, Congressman from Massachusetts, has introduced a bill in Congress entitled "A bill declaring an embargo on anthracite coal," being H. R. No. 12827, which declares that the conditions at present prevailing in the production and distribution of anthracite coal constitute a national emergency; and



Whereas great distress and hardship exist in New England on account of such coal shortage: Therefore be it

Resolved, That the House of Representatives of the General Court of Massachusetts urgently requests that Congress take immediate steps for the passage of appropriate legislation to relieve the great distress existing in New England, and hereby records itself in favor of immediate passage of H. R. No. 12827; and be it further



Resolved, That copies of these resolutions be sent by the secretary of the Commonwealth to the President of the United States, to the Presiding Officers of both branches of Congress, and to the Senators and Representatives in Congress from this Commonwealth

The Bituminous Operators' Special Committee has formally denied a report that it has raised a question as to the constitutionality of the Coal Commission law. A meeting of the full Special Committee in Washington on Feb. 15 has been announced.

A GOOD MANY FUEL COMPANIES can comply with the order to supply substitutes for coal without departing any from their former methods.—*New York Tribune.*

Production and the Market

Weekly Review

There is a persistent dullness in the bituminous coal market and a monotony in the anthracite trade relieved only by the effort of New York and New England to cut off anthracite shipments to Canada. Prices of soft coal are headed downward, production is slipping and thoughts are turning to spring.

Coal Age Index of spot prices of bituminous coal records 296 this week, a drop of 16 points from 312 on Feb. 5. This brings the figure back to that on July 1, 1922. The average price on Feb. 12 was $3.58, a decrease of 20c. compared with $3.78 on Feb. 5. Production of soft coal dropped to around 10,200,000 tons last week after hanging at 11,000,000 tons for many weeks.

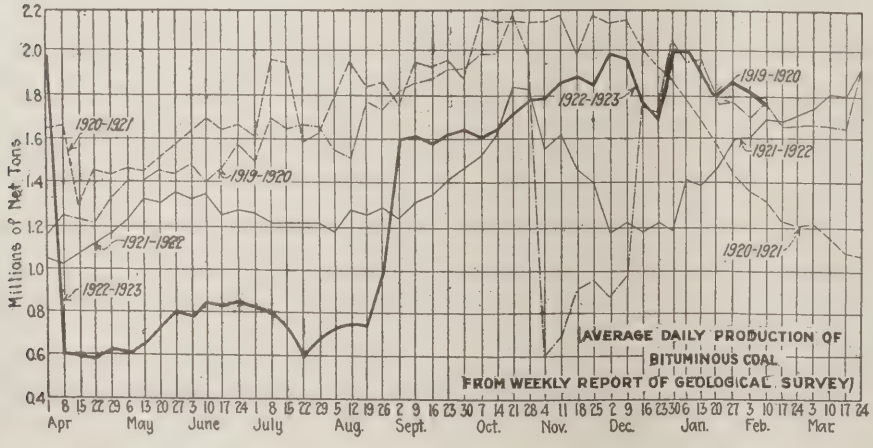
Secretary Hoover on Feb. 13 said he did not believe it best to advise consumers of coal to add materially to stockpiles now. Until the transportation situation improves there can be no large movement of coal for future use. He intimated, however, that buying for storage should begin in spring just as soon as the carriers are available to handle it.

Buyers on the Lookout for Bargains

Buyers are taking little interest in the situation, save to pick up bargains. Contracts are being discussed in some quarters but among customers the feeling prevails that it will be possible to buy in the open market later at lower figures than those at which contracts can be negotiated at present.

The market for Pennsylvania coals in New England is being held firm through the continuance of embargoes against certain of the Hudson River gateways, which act as a prop to prices on cars for inland delivery, where quotations remain reasonably firm at $10 upward per gross ton delivered. These embargoes and those referred to in last week's review concern only the movement of bituminous coal into New England. While they have not operated to affect notably the total shipments, these embargoes are exceedingly troublesome to both shippers and consignees. Anthracite is not interfered with in any way by these embargoes.

The all-rail movement of coal to New England and eastern New York for the week ended Feb. 3 included 3,447 cars of anthracite and 3,265 cars of bituminous coal, forwarded through the principal gateways over the Hudson River and through Rouses Point. This was a decrease of 648 cars of anthracite and an increase of 375 cars of bituminous coal as compared with the previous week, but approximately the same as in the corresponding week a year ago.



Heavy Oil Receipts in New England

In the calendar year 1922 New England got but 56 per cent as much anthracite as in 1921, which accounts for the active interest in coal in that part of the country. Of bituminous coal New England received 85 per cent as much in 1922 as in 1921, but some 2,000,000 tons of this was imported from abroad. Crude oil, however, poured into New England at the highest rate recorded. Against 112,779,100 gallons in 1918, 448,217,000 gallons in 1920, and 730,742,000 gallons in 1921, the receipts in 1922 were 767,323,000 gallons.

New England and northern New York as well have not suffered for lack of soft coal, however. Their trouble is that they do not know there was a strike last summer and that their inability to get the usual quotas of domestic anthracite is not the fault of the coal man but of the coal digger who would not work last summer. There is little sympathy elsewhere over the country with this effort to cut off Canada's hard-coal supply.

Production of anthracite remains close to the 2,000,000-ton mark. Producers have no difficulty in disposing of the domestic coals, including buckwheat, which continues to be used as a substitute for the larger sizes, but the steam sizes are slightly easier.

"Present estimates of soft-coal production in the week ended Feb. 3 indicate a total output, including coal

(*a*) Subject to revision. (*b*) Revised from last report.

shipped, mine fuel, local sales and coal coked, amounting to 10,587,000 net tons," the Geological Survey says. "Revised estimates for the week before show 10,985,000 tons. Instead of nearly uniform rate of production at about 11,000,000 tons a week, as indicated by early returns, there is now indicated a gradual decline in the production since the beginning of the year.

"Preliminary reports of cars loaded during the present week (Feb. 5-10) show 41,540 cars on Monday, a drop to 30,975 on Tuesday, and further decline to 29,303 on Thursday. The indicated total output for the present week is therefore about 4 per cent less than for the week preceding, and will be between 10,100,000 and 10,200,000 tons."

Midwest Thankful for Cold Weather

Continued low temperature for several days kept the bottom temporarily under the domestic market throughout the Chicago and Midwest region. There is no buying beyond the immediate needs of the moment, but that is heavy enough to move with comparative ease all the larger prepared sizes in southern Illinois, the Fourth Vein Indiana field and eastern Kentucky. The other regions had to work a little to place everything they produced because such territories as central Illinois got better car supply than they wanted.

Southern Illinois ran between 2½ and 3 days during the week and stuck to the circular of $5.50 for lump a little more closely than during the last week of January, before the cold weather. Operators outside the association group sold down to $4 for 6-in. lump and from 50c. to $1 under the list on egg and nut sizes, those being the only prepared coals that are really dragging bottom. Screenings are in considerable volume just now while domestic production is healthy and Franklin County and Indiana Fourth Vein are holding to their $2.50 level quite consistently, with the likelihood of dropping no lower.

The Standard field east of St. Louis moved a considerable volume of coal because its car supply grew better. This prevented any change in prices. The St. Louis market took a great deal of both Standard and Mt. Olive coal during the coldest days but at the end of the week the weather had warmed, with the inevitable result. Both domestic and steam trade went back into a lull with the call being for cheaper coals. Retail yards are well cleaned up. Prices remain unchanged. Rail service through St.

* Net tons, f.o.b. mines. † Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 296, Week of Feb. 12, 1923. Average spot price for same period, $3.58. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighed in accordance first with respect to the proportions each of slack, prepared tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

Louis is getting unsatisfactory again. Congestions are developing.

Kentucky demand during the week was largely for lump coals. All other sizes moved stiffly in the unaccustomed cold that visited Louisville. A slight improvement in car supply and high river stages have combined to aid coal movement just at the right time, for the buyer's benefit, so that some recessions in price were made. East Kentucky block coal got down to $5.50, 2-in. lump to $4 and mine-run to $2.25 in some instances, with screenings at $2.25@$2.50. Best Kentucky lump sold at $3.50@$4; mine-run $2.25@$2.50 and screenings $2@$2.25, spot at the mines, buyers paying brokers' charges.

Of course the only spot coal that sells any Kentucky or Midwestern market is that which is rolling and close to destination. Thus the market all around is tiptoeing along, refusing to take a ton of coal that might have to be carried into the next warm spell, which might arrive at any moment.

Northwest Stirs a Little

Cold weather—bitter cold, ranging down as low as 33 below zero for a day or two at the Head-of-the-Lakes—stirred the retail markets of the Northwest during the week just closed. Most of the trade was in anthracite, Pocahontas, coke and hard-coal substitutes for domestic use. This demand was strong enough to push anthracite hard against the top of the circular, breaking through occasionally at Milwaukee, where anthracite was listed at $15.75 for egg, $16.10 for stove and $16 for nut. Pocahontas screened sizes are moving at $13.75 wholesale and $15.75 retail and mine-run at $11@12.50. On that market Pittsburgh, Hocking Valley and Youghiogheny, pile-run and screenings advanced 25c. largely because car-ferry congestion holds back all Eastern coals. Rail deliveries, however, are so good that Illinois and Indiana pile-run and small screened sizes went off 50c.

At all docks the domestic sizes have been moving off steadily, leaving screenings in surplus. A little railroad buying is still noticeable but most roads appear to be satisfied with what they have under contract. Duluth notes that shipment off the docks there is easing up as compared with last year. The January total was 13,683 cars as compared with 24,521 cars in January of 1922, when the country was getting ready for a strike. Eastern lump is still reasonably strong at $9.50; run of pile, $8.25@$8.50 and screenings are sagging at $6@$6.25.

West Awakens Somewhat

Colorado and Utah during the past week shivered and bought coal. The result of the zero weather and stiff breezes was that retailers whose supplies were low demanded coal at once and steam trade livened up noticeably. For a week mines in almost every district worked every day and railroads did a reasonably good job of moving mine outputs. Raw weather along the Pacific Coast draws more coal in that direction too. Thus, for the time being, the mountain states and Far West are in a brisk condition and prices are not dropping. In Kansas City the weather produced no noticeable effect for the better. The market was as full of holes as a Swiss cheese, but no sudden drop in prices appeared. Kansas lump continues at $5; nut, $4.50; mine-run, $3.50 and screenings, $2.50.

Softness characterizes the Ohio coal trade both as to steam and domestic coals. Buying is reduced to present needs, as few consumers are trying to stock up for the future. In some instances reserve piles are being used. Distress coal in the Columbus market is heavy and as a result some extremely low prices are reported in order to dispose of it. Retail stocks are only fair, dealers buying only for the present, believing that prices will be lower. Michigan points are absorbing a fair tonnage.

In the Cincinnati market similar conditions exist. Rejections are the order of the day. There is little talk of contract making, buyers as in the east, apparently being determined to hold off. Car supply is reported as improving, and three days a week are being reported from some sections.

Mines in the eastern Ohio No. 8 district are working less than 35 per cent of full time. Cumulative production figures from Jan. 1 to Feb. 3 indicate an output of 1,551,000 tons, or about 50 per cent of capacity.

Bituminous-coal receipts at Cleveland for industries and retail yards during the week ended Feb. 3 show a decrease of 51 cars from the preceding week. Total receipts were 2,887 cars, divided 2,117 cars for industries and 770 for retail yards. Receipts for industries decreased 103 cars as compared with the preceding week, while arrivals for retail yards show an increase of 52 cars over the preceding week. Cleveland receipts have averaged 2,930 cars per week since Jan. 1, as compared with 2,345 cars per week during the last quarter of 1922.

In West Virginia low-volatile as well as high-volatile coals felt the effect of a falling. Lump was the least affected. High-volatile mine-run did not average more than $2.50 a ton throughout the week, the range extending to $3. Nut and slack ranged $2.50@$2.65 and egg and lump $3.50@$4.50.

Car supply in West Virginia, Virginia and northeastern Kentucky was not as conducive to large movement of coal as during the preceding week.

The first and most prolonged touch of real winter weather of the season at Birmingham Ala., was experienced last week. It was ushered in by cold rains followed by sleet and a light snow, which played havoc with power transmission lines and caused a heavy loss in coal production during the first two or three days of the week. Weather conditions also affected labor.

Seaboard Market Dull

Light shipments of steam coals all-rail are about the only indication of firmness in the present market in New England. Several large consumers who were planning to make purchases at this time have concluded now to wait until the market settles. Among these are textile manufacturers and certain power companies who are banking on liberal water power within a month's time. Congestion at the rehandling wharves is clearing up and there is much less pressure generally to get forward supply.

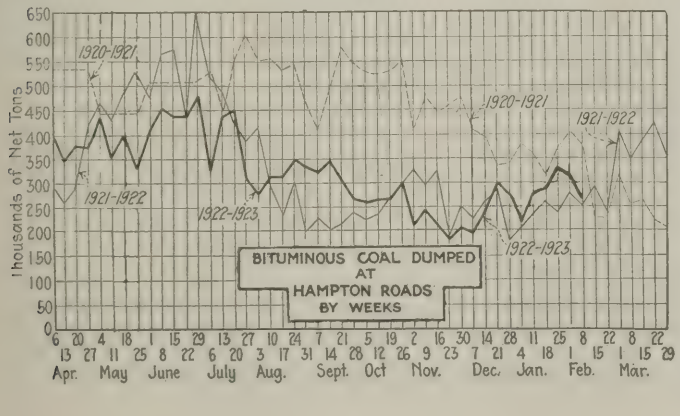
At Hampton Roads certain of the agencies have made strenuous efforts to place accumulations while the market was at all favorable. Spot prices have been scaled down to $6.90 per gross ton f.o.b. vessel, and 15@25c. less has been rumored. There are ample tonnages on hand at the Virginia terminals, and the trade expects to see quotations gradually slump to $6.50, or around $3.50 per net ton f.o.b. mines. A few shippers, however, are inclined to think that $3.50 per gross ton will be nearer a going price, especially on contract.

The Pennsylvaia grades also are gradually sagging off in price, although a pronounced slump has been arrested by continuing difficulties in transportation. A larger volume is moving from central Pennsylvania to piers at Philadelphia and New York, but much of this is contract coal diverted to tidewater to facilitate delivery. Prices average around $4 per net ton at the mines for medium grades, with the more favorably known coals selling still at $4.50@$4.75.

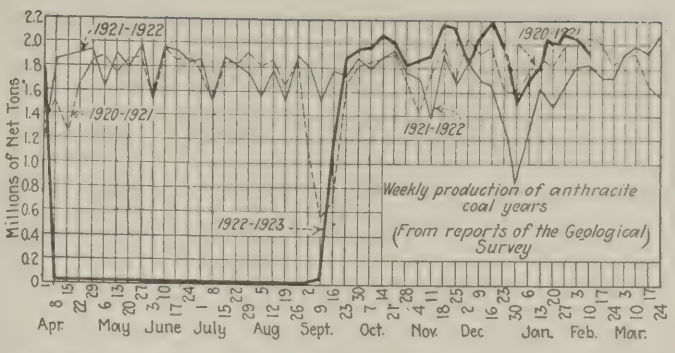
Operating interests are busy canvassing for contracts throughout this territory. The Hampton Roads shippers are expected to retain much of the tonnage obtained last year, but aside from a few special cases the Pennsylvania producers are not likely to close much business of a comprehensive nature, at least not on the present cost basis. The differential is much too great as compared with the smokeless West Virginia coals to admit of much large tonnage except within the nearer strip which is now reserved to all-rail shipment without competition from tidewater.

Conditions are quiet along the seaboard. More than 70,000 tons of British coal arrived in New York harbor during last week, not including a cargo of British furnace coke consigned to a large retail coal firm and which will be offered for sale through the regular channels.

There is still much interest in the contract situation but buyers are not inclined to enter into agreements.



The outstanding feature of the Baltimore market are the prospects for a more active bunker business. This trade is encouraged by the belief that a number of ships, including American shipping board vessels, seem likely to be in the market shortly for considerable quantities offered.



Anthracite

Demand for the domestic sizes of anthracite continues strong. The larger companies and independent producers are having no difficulty in disposing of their output but the smaller operators have found it necessary to shade their quotations slightly. Retail dealers in the outlying district who are located at points where it takes from three to four weeks for shipments to reach them continue to cancel orders.

"The production of anthracite declined slightly in the week ended Feb. 3," says the Geological Survey. "The total output, including mine fuel, local sales and dredge and washery output, is estimated at 2,056,000 net tons on the basis of 39,321 cars loaded as reported by the principal anthracite carriers.

"Early returns from the railroads on loadings this week (Feb. 5-10) indicate a somewhat smaller output, probably a little less than 2,000,000 tons."

Coke Market Weaker

The coke market has weakened in price rather sharply the past week or ten days, chiefly on account of decreased buying for heating purposes. Some steel companies are rumored to have entered the market for spot or prompt coke.

Utilities Continue to Consume More Coal

Electric public-utility plants consumed 3,586,346 net tons of coal during December, according to a recent report of the Geological Survey. This compares with 3,350,761 tons consumed during November, according to corrected returns.

The average daily production of electricity by public-utility power plants in December, again broke all records of output, making the sixth time that a record has been established since May. The daily production of electricity in December was 146,700,000 kw.-hr. The total output for the period January to December, inclusive, was 47,676fi049,000 kw.-hr., an increase of more than 16 per cent over that for 1921.

Foreign Market And Export News

Welsh Coal Trade Shows Increased Activity; British Production Increases

British mines produced 5,644,000 tons of coal during the week ended Jan. 24, according to a cable received by *Coal Age*. This was the largest tonnage produced during any week of the year. Quotations on some grades are slightly advanced from last week.

The Welsh coal trade is in good condition. Inquiries continue to come for coal for export. So far the Welsh coal trade has not been affected by the German situation. France is buying well, and exports to Germany are sustained, but there is no unusual pressure.

Steam coal is being heavily booked in all regular markets. German business on a heavy scale has not yet arrived, though trading to the extent of 150,000 tons has been done. Collieries are all well sold up and in anticipation that demands will be stimulated are asking higher prices for forward shipment. Demand from South America is active.

Prices throughout north England are rising generally and steadily. Contracts have been placed with Durham mines by gas companies for four lots of second class gas coal, ranging from 50,000 to 60,000 tons each, at prices between 22s. 3d. to 22s. 9d. f.o.b.

Germany has purchased in the Humber market over 250,000 tons of Derbyshire and Nottinghamshire steam coal for shipment during February, March and April.

Hampton Roads Market Dull

Business was dull at Hampton Roads on a falling market due to general oversupply in sections furnished from this point. Coastwise business slowed up, but prices were approaching a point where competition with British coal in the North may be made possible.

Dumpings were slowed up because of the recent storm which froze coal cars at all piers and made several extra operations necessary before they could be dumped. Many vessels were delayed in this manner.

There was a feeling that the bottom of the market is in sight, and that movement will be increased in a short time.

French Tonnage Figures

The following tabulation shows the production, imports and exports of coal, coke and patent fuel during the first eleven months of 1922, the balance being placed at the disposal of consumers or otherwise disposed of:

COAL	Metric Tons
Output	29,094,394
Imports	20,157,381
	49,251,775
Exports	1,847,062
Placed at the disposal of consumers or transformed into coke or patent fuel	47,404,713

COKE	Metric Ton
Production (coke-ovens annexed to collieries)	901,111
Imports	4,599,358
	5,500,469
Exports	430,848
Placed at the disposal of consumers	5,069,621

PATENT FUEL	
Production (patent fuel works annexed to collieries)	2,543,732
Imports	1,305,348
	3,849,080
Exports	96,638
Placed at the disposal of consumers	3,752,442

There were 20,157,381 metric tons of coal imported into France during the first eleven months of 1922 from the following countries:

From	Metric Tons
Saar	3,186,494
Great Britain	10,825,544
Belgium	2,201,833
United States	23,255
Germany	3,363,261
Netherlands	552,757
Other countries	4,237
Total	20,157,381

British Coal Exports Increase

Exports of British coal to European countries in 1922 amounted to 48,291,462 tons, according to figures issued by the Bankers Trust Co., of New York. This was more than 8,000,000 tons less than in 1913. British coal exports to Germany were approximately 8,346,000 tons as compared with about 8,952,000 tons in 1913. The figures for Europe and South America in detail follow, in thousands of tons:

To Europe:	1913	1922
France	12,776	13,579
Italy	9,647	6,342
Germany	8,952	8,346
Russia	5,998	584
Sweden	4,563	2,523
Belgium	2,031	3,480
Netherlands	2,018	6,067
Other European Countries	10,854	7,361
Totals	56,839	48,291
To South America:		
Chile	589	84
Brazil	1,887	1,013
Uruguay	724	503
Argentine	3,692	2,021
Totals	6,892	3,621

A large gain was made in 1922 compared to 1913 in British coal exports under the classification "other countries," which includes the United States, says the statement. The exports for 1913 under the above classification amounted to 1,749,877 tons, while in 1922 they were 6,168,825 tons. That increase was principally due to the demand for British coal in the United States because of the mine dispute.

News Items From Field and Trade

ALABAMA

A. R. Long, who has been vice-president and general manager of the **Brookside-Pratt Coal Co.** for several years, was elected president at a recent meeting of the directors of the company. He succeeds James Bonnyman, who severed his official connection with the company several months ago to go to Cincinnati, headquarters of a new company in which he is interested and which is extensively engaged in coal mining in Tennessee and Kentucky.

The Leeds Coal Co. is sinking a slope mine in the Cahaba Valley, east of Birmingham. The company was recently organized with I. F. Mankin, president; Henry Neny, vice-president and general manager, and W. H. Moore, secretary-treasurer. A spur track will be built to the new operation from the McCoomb's switch of the Central of Georgia Ry. Messrs. Mankin and Moore are residents of Jasper and Mr. Neny makes his headquarters in Birmingham.

At the recent examination held by the state board of examiners headed by C. H. Nesbitt, chief mine inspector and chairman of the board, thirty-three certificates were awarded to applicants who successfully passed the examination as first-class mine foreman, nine second class, and eleven received certificates of competency as fire-bosses.

The Hilliard Coal Co., with an opening at Hilliard, six miles west of Jasper, **is installing electrical machinery** and making other improvements to increase production.

The Monroe-Warrior Coal Co. is reported to be making arrangements to open new mines at Nauvoo, Walker County.

The Sterling Coal Co. has been incorporated at Jasper with a capital stock of $15,000 and the election of the following officers: President, Dr. S. S. Shores; secretary and treasurer, Albert Murray. The company will **develop new mines and lay tracks and tram lines** to the main line of the Frisco R.R.

COLORADO

The Coal Consumption of Denver and Denver's "500,000 by 1930" campaign will both be boosted when the first part of the new Chicago, Burlington & Quincy R.R. shops is put into service in that city. Coal-handling machinery with an hourly capacity of 50 tons is being installed; the employment of over 700 men initially will mean an addition of 3,000 people to Denver's population, and a further increase in coal consumption. The $2,500,000 contract, to be completed by September, 1923, provides a machine and erection shop to care for 175 engines, boiler and blacksmith shops, storehouse, oil house and power plant. The work is under the direction of W. T. Krausch, of Chicago, engineer of buildings for the C., B. & Q.

George P. White has been appointed sales manager of the **Huerfano Coal Co.** He formerly was connected with the Colorado Fuel & Iron Co.'s sales force.

The steel mills are working full time at Pueblo, and the Trinidad and Walsenburg mines are supplying them a total of 5,000 tons of coal per day.

The Leyden Coal Co.'s mine lost five days in January. The Denver City Tramway Co. and the Denver Gas & Electric Light Co. are supplied by this company.

DELAWARE

The du Pont explosive known as **Monobel No. 8 has passed all tests,** including the low freezing test, of the U. S. Bureau of Mines necessary to place it on the list of permissible explosives for use in coal mines. It is now entitled to the official L. F. designation and will hereafter be branded as Monobel No. 8 L. F.

ILLINOIS

Ora D. Dillavou, formerly one of the partners of Boone-Dillavou Coal Company, Champaign, has withdrawn from that firm to assume charge of the sales force of the Harris-Dillavou Co., also of Champaign, handling coal and building material. The business of the Boone-Dillavou Co. will be closed.

Fire recently caused several thousand dollars damage to the top works of the **Ernest Coal Co.** mine near Johnston City. The blacksmith shop, machine shop and several other nearby buildings were totally destroyed by the fire.

The **Pyramid Coal Co.** has been granted articles of incorporation at Springfield with a capitalization of $225,000. The offices of the new organization are at Marion.

The "Heato" mine at Carrier Mills **will resume work soon,** according to announcements given out. The property was recently purchased by the Carterville Fuel Co., of Carterville. It is reported that the company will open a strip pit on the land joining the mine.

Articles of incorporation have been filed for the **Southern Illinois & Kentucky Railroad Co.** at Mt. Vernon, Jefferson County. This paves the way for construction of the **new Illinois Central cut-off** to be built from Edgewood to Metropolis through the center of the vast **Franklin and Williamson County coal fields.** The new route will make the haul much shorter than the main line of the road via Carbondale and Duquoin, and will be used for freight and coal hauling almost exclusively, running only accommodation passenger trains. The incorporation papers were dated Jan. 11, 1923, and the capital stock is $40,000 divided into 400 shares of $100 each. The incorporators and directors are prominent Illinois Central officers: C. H. Markham, president of the Illinois Central R.R.; C. M. Kittle, M. P. Bleuvelt, W. S. Horton and Bert A. Beck.

The United Mine Workers have just opened the **American Hospital** in Johnston City. The institution is neat, clean and attractive. Dr. Fred Greenbaum, of West Frankfort, is in charge of the new hospital.

Mine No. 18 of the Chicago, Wilmington & Franklin Coal Co. at Herrin recently **broke its hoisting record** by bringing to the surface a total of 4,357 tons of coal in eight hours. The previous record of this mine was 4,175 tons. A total of 1,381 dumps were made on the day of this last record. The company's Orient No. 1 mine holds the world's record for a single day's hoist of 8,218 tons, and is located only a few mines from No. 18 mine.

Several of the mines located near Springfield have **reduced the price of coal for local delivery** 50c. per ton. A mild winter, with the consequent lessening of demand for coal over normal times, is given as the reason for the reduction.

J. W. Colliver, sales manager for Old Ben Coal Corp. of Chicago, is spending a month at Palm Beach, Fla.

The Standard Conveyor Co. has acquired by purchase all the rights, titles and patents pertaining to the "Brown Portable" line of portable and sectional piling, elevating, conveying, loading and unloading machinery for the handling of packed and loose materials. This line of machinery has been manufactured by the Brown Portable Conveying Machinery Co. at North Chicago for ten years. Until further notice the plant will be continued in operation by the Standard Conveyor Co.

An explosion in Mine No. 1 of the **Superior Coal Co. near Gillespie** caused injury to eleven men who were entering the mine one morning recently, their lamps setting fire to a pocket of gas which had accumulated during the night. All the men were burned. John Keeves was the most severely injured.

The **state mine rescue headquarters has been moved** from Harrisburg to Eldorado by recommendation from the State Department of Mines and Minerals. The station will be located on the top floor of the First State Bank of Eldorado Building and will be in charge of Frank Patterson, manager.

The Zeigler Coal & Coke Co. has been granted incorporation papers at Springfield and will mine and sell coal. The company will have headquarters in Zeigler and is capitalized at $18,000. The incorporators of the new concern are E. A. Bronson, Wm. J. Warr and Frank M. Wakefield.

The Chicago & Eastern Illinois R.R. announces that **a $500,000 extension** will be made in the shops of that company in Salem. The road handles much of the Franklin and Williamson County coal mine output through Salem and has found the present facilities inadequate.

The St. Louis Coke & Chemical Co., with large plants at Granite City, and main offices in St. Louis, announces that it will start construction soon on a **new blast furnace** which together with other improvements will cost approximately $1,500,000. The plant consumes large tonnages of southern Illinois coal daily and is at present turning out large amounts of benzol, which constitutes the basis of the motor fuel sold under the name of benzol gas. According to announcements given out by C. R. Holzworth, superintendent of the plant, the new equipment to be installed will practically double the company's present output of coke and byproducts.

The St. Louis Coal & Iron Co. will open a new mine in Johnston City about March 1, according to reports. The mine will be equipped with electrical mining and haulage machinery and will be modern in every respect.

The **Cloverleaf Coal Co.,** of Marion, has been incorporated and capitalized at Springfield at $150,000. The company will mine and sell coal and is expected to open a new mine at Marion in the near future.

A part of the surface plant at **Franco Mine No. 1,** at Johnson City, belonging to Cosgrove & Co., was recently **destroyed by fire.** This is not expected to interfere seriously with operation, and the owners say they will be able to replace the buildings in a month.

INDIANA

Fire of undetermined origin recently caused a $20,000 loss to the old Freeman mine, now known as the **Howe-Coulter mine No. 2,** located at the edge of Bicknell. Firemen were able to save the engine house and its equipment, but virtually all the other superstructure burned. Thirteen men at the bottom of the shaft when the fire was discovered escaped without injury. The mine was idle the day of the fire. William Howe, John Coulter and Robert McCleavy, all of Chicago, are the principal stockholders in the company. The mine formerly was operated by the Tecumseh Coal Co. and has been producing Fifth vein coal for more than twenty years.

Unscrupulous coal dealers will have a difficult time misrepresenting the kinds and grades of coal they sell to consumers if a bill introduced in the Senate of the General Assembly of Indiana by Senator Rowland H. Hill, of Carthage, goes through. Senator Hill is a retail coal dealer. The bill would require every wagon load of coal to be accompanied by a delivery ticket showing in pounds the gross weight of the load and the tare weight of the delivery vehicle. One of the tickets would be given to the purchaser and the other retained by the deliveree. The ticket would also show the state in which the coal was mined, the name and number of the vein or seam from which the coal was taken and the size and grade of the coal.

Creation of a state department of mines and mining to consist of two operators, two miners and the state mine inspector is asked in a bill introduced in the Indiana General Assembly by Clem J. Richards, of Terre Haute, a mine operator. The bill is the direct result of the findings of the commission created by the 1921 Legislature to codify all mining laws and make recommendations for the betterment of the industry.

Only three new provisions are contained in the **codification of the mining laws of Indiana** prepared by a state codification commission and introduced as a bill in the General Assembly by Senator Clem J. Richards, a coal operator. One provision seeks to protect miners from the danger of oil and gas wells that are drilled through coal seams, by providing that the well owner must incase his drilling in concrete or piping. Another provision governs the placing and use of electrical appliances in mines and the third deals with the manner in which worked-out parts of mines shall be sealed off from other parts. The bill introduced previously by Mr. Richards providing for a state mining department, separating the present state mining inspection work from the state industrial board, is not a part of the codification bill. The proposal, however, has the unanimous approval of the codification commission, Governor McCray, the industrial board and operators and miners in the state, according to Cairy Littlejohn, state mine inspector. **It has passed the Senate** 40 to 3 and has gone to the House.

The Sterling Collieries has been organized in Indianapolis for the purpose of doing a general coal mining business. The company has a capital stock of $100,000 and the organizers are William Schrolucke, John A. Templeton and Clarence W. Means.

The mines of the **Archbold Coal Co.** at Newburg, after being shut down for three weeks, reopened recently, when about 100 miners returned to work, following a strike which was caused by the miners walking out when the company changed brands of powder without first consulting the workers.

KENTUCKY

The F. T. Slider Co., Louisville, Jeffersonville and New Albany, handlers of sand, gravel and coal, operating its own river equipment, has recently placed orders for **six all-steel barges** with the Howard Shipyard Co., at Jeffersonville. This is one of the first companies in that district to build all steel barges for towing coal, sand, etc.

Willard R. Jillson, state geologist, in a recent talk in Louisville, said that during the first six months of 1922 Kentucky produced 17,267,132 tons of coal and during the first eleven months, on incomplete records, 36,361,000 tons were produced.

The two mines of the Coil Coal Co. have been sold by the Coil interests to the West Kentucky Coal Co., of Paducah and Sturgis. The report of the sale stated that the properties were purchased by W. F. Bradshaw, tobacco and insurance man; C. F. and H. L. Richardson, Paducah and Sturgis respectively, and T. E. Jenkins, Sturgis. Other than Bradshaw the purchasers are all connected with the West Kentucky Coal Co. The mines have a capacity of 1,250 tons daily, some reports stating 2,000 tons.

K. U. Meguire, of the Harlan Coal Co. interests, Louisville, reports that the **Letcher Coal Mining Co. has succeeded the Amburgy Coal Co.**, operating in Letcher County, and the capital has been increased from $185,000 to $225,000. Mr. Meguire continues as president. The Meguire interests recently took over the Perciful-Gorman coal mine interests, in the Hazard field of Perry County, known as the Perry County Coal Corp., on Carrs Fork. That concern has become the Black Hawk Coal Co.

A report from Smithland, in a district from which very little coal has been reported, is to the effect that a 5-ft. vein of good coal has been struck on the farm of H. F. Moore, near Carrsville, at a depth of 107 ft. At 12 ft. a 12-in. vein was found and a 20-in. vein at 60 ft. It is reported that a stock company is being formed to promote the mine and that a shaft will be sunk next spring or summer.

Notice has been filed with the County Clerk at Louisville affirming ownership of the **Kentucky Block Coal Mining Co.**, of Blue Diamond, by Harry F. Buloock and V. B. Renaker, Lexington; and C. S. Foyle and John Hayslett. The company operates in Perry County. Buloock and T. E. McConne also affirmed ownership of the **Kentucky Jewel Coal Co.**, of Lexington.

Charles Buddeke, of the Charles Buddeke Coal Co., Louisville, and his partner, Denver P. Cornett, who also is connected with the Cornett Lewis Coal Co., Harlan County, are **planning to install automatic unloading equipment at the Louisville retail yard**, but have not been able to decide on the best equipment as yet. Plans have been considered for an elevated trestle for unloading cars to hoppers, and also for a dumping pit, using electric conveyors to hoppers, or locomotive crane to hoppers and trucks. The city has a yard next door, which has a low elevated track, which could be carried over to the Buddeke yard at a higher elevation, but Buddeke is opposed to unloading from track, contending that there is too much breakage in soft coal.

As a result of heavy rains throughout the Ohio Valley, **the Ohio and tributary streams are rising rapidly**, the river being close to flood stage at Evansville, Ind., and some points, but affording a fine boating stage for movement of coal tows in the Kentucky and upper Ohio, and from Western Kentucky south to points in Louisiana and Arkansas. The present high stage is very welcome to river coal men following the long summer months in which the river was a dried up stream.

MARYLAND

The tipple of the Sullivan Bros. Coal Co. at Carlos, near Frostburg, was **destroyed by fire** on Feb. 1. Nearly 100 men were thrown out of work.

MINNESOTA

There seems to be **no end to the activities of the Ford interests.** With the announcement of the establishment of a large manufacturing plant on the west edge of St. Paul, adjacent to the Minneapolis labor market, came the report that coal was to be brought up from the Illinois mines on barges on the river and unloaded at the plant. But it is also given out on what seems to be good authority, that the Ford interests are also about to buy a coal dock at the Head-of-the-Lakes.

The Minneapolis & St. Louis R.R. Co., J. D. McCarthy, general purchasing agent, Minneapolis, **is taking bids** until Feb. 14 for furnishing coal from March 1 to Dec. 31, 1923, for various sizes (mine-run, lump, egg and screenings) the quantity to be 300 tons to 1,000 tons per day daily except Sundays.

The report of Ivan Bowen, as State Fuel Administrator of Minnesota, recommending state control of fuel selling, has thoroughly aroused Twin Cities coal men. They declare that neither the state nor the nation has as yet demonstrated any ability to administer business any better for either the public or the industry than private owners do. They see in the report merely a bid for votes—a regular political movement.

The Republic Coal Co., of Minneapolis, and affiliated concerns, Pratt Bros., the Midway Coal Co. and others, has moved from the Franklin Building to 629-635 Palace Building, where larger quarters are available.

A bill has been introduced in the Legislature which would make it **unlawful for mining and fireboss certificates to be granted aliens.** It has been reported on favorably in committee. Another bill would abolish the Public Utilities Commission. Former Chief Justice Corfman has been made a member of this body in place of Judge Heywood, deceased.

The trial of the coal and lumbermen charged with price-fixing following a grand jury investigation last fall, will not come up till April or May, it having been again postponed.

MISSOURI

The Mulberry Hill Coal Co. is a new concern just incorporated for $200,000 and will maintain offices in St. Louis. The company will mine and sell coal. The incorporators are W. F. Zerban, E. E. Carter and F. Nold.

NEW YORK

The Morrison & Risman Co., manufacturers and jobbers in railway track equipment, handling new and relaying rails, frogs and switches, spikes, bolts, nuts, tie plates, etc., has been incorporated with a capital of $500,000, fully paid in. The officers of the company are S. Morrison, president; S. Risman, vice-president; R. L. Morrison, treasurer, and S. H. Risman, secretary. The company maintains general offices in Buffalo, N. Y.; a district sales office in Philadelphia, Pa., and has works and warehouses in East Buffalo, N. Y., and Lebanon, Pa.

NORTH CAROLINA

The Carolina Coal Co. of Sanford is reported to have let contracts for the construction of three miles of railway to connect the mines at Coal Glen with the Norfolk Southern R.R. and the Southern Ry. between Cumnock and Gulf.

OHIO

A strike of 400 miners in the employ of of the Rail & River Coal Co.'s mine at Bellaire early in February in the face of an order from President Ledvinka of Ohio Subdistrict 5 directing them to remain at work was denounced by Ledvinka, who said: "These men have no grievance and I am ashamed to confess that men in my district would be guilty of such a flagrant violation of the contract between the operators and the United Mine Workers." The strike appears to have grown out of several minor complaints as to working conditions, but notwithstanding the adjustment of such differences the miners walked out. Commenting further on the action of the miners in striking Ledvinka said he had ordered the men to return to work forthwith.

A. Y. Miller, foreman of the U. S. Bureau of Mines Car No. 7, recently spent a week in Kirksville, where he gave free instructions in first-aid work to all miners of Adair and adjoining counties, who availed themselves of the opportunity. There is a strong possibility of the next state-wide meeting in first-aid and rescue work being held in Kirksville, in which first-aid teams from all parts of Missouri will participate.

Mrs. W. K. McKiernan, widow of William H. McKiernan, a miner of Moberly, who gave his life July 18, 1919, in saving Bob Anderson, a carpenter, from suffocating in the Kimberly mine near this city, **has been awarded abronze medal and $70 a month from the Carnegie Hero Fund Commission**, with an additional $5 a month for each of two children. McKiernan's heroism followed an accident at the mine when black damp got into the compartment in which Anderson was working.

PENNSYLVANIA

An Eastern syndicate has acquired 2,000 acres of coal land in northern Cambria County. This land was the property of the Central Cambria Coal Co. The price paid was $325,000. T. Stanton Davis, of Ebensburg, one of the principal owners, conducted the negotiations. The land contains Miller seam coal of the Wilmore basin.

A state charter was recently issued to the **Pittston Fuel Co.**, Scranton. It will mine and prepare coal for the market. Its capital is $25,000, and Richard R. Walsh, Scranton, is treasurer and one of the incorporators, the others being Patrick R. Jordon and John J. McGuire, Scranton.

The Old Buffalo Coal Co., Philadelphia, has notified the State Department at Harrisburg that it has changed its corporate title to the **Pennsylvania Coal & Mining Co.**

Five Johnstown mines of the Cambria Steel Co. broke all output records in January by producing 187,804 tons of coal. The previous high mark for these mines was made in November, 1922. The Slickville mines, in Westmoreland County, which are a part of the Cambria mining department, produced 66,700 tons in January, and the mines of the Union Coal & Coke Co., a subsidiary of the Midvale Steel & Ordnance Co., located in Washington County, produced 150,658 tons, bringing the total production for the entire department to 405,162 tons for the month.

A new coal-mining company has been organized at Curwensville, Clearfield County, to be known as the **M. & N. Coal Co.** At the organization J. Howard Thompson was elected president; L. C. Norris, secretary-treasurer; C. O. Norris, A. Z. Wolf and John W. Norris, of Curwensville, and Don Mahaffey and F. C. Mahaffey are the other members of the firm. They will operate on the Robert Mahaffey tract, consisting of some 2,000 acres, underlaid with Moshannon vein, and near the New York Central R.R. at Mahaffey.

An appeal has been taken against increases in coal valuations in Greene County. The valuations have been advanced from 20 to 75 per cent and have increased the taxable coal values in the county by $6,000,000. In all 502 appeals have been taken.

George R. Marietta has been elected president of the Connellsville Coke & Fuel Co. to succeed his father, the late Rockwell Marietta. W. F. Soisson was re-elected vice-president and W. H. Soisson, secretary and treasurer. The following board of directors was elected: V. H. Soisson, W. F. Soisson, W. H. Soisson, William H. Marietta, J. G Percy, George R. Marietta, and Clarence B. Marietta, the last-named being a new member of the board.

Engineers from far and wide in northeastern Pennsylvania attended the **annual banquet of the Engineers' Society of Northeastern Pennsylvania**, held at Hotel Casey, Scranton, Feb. 1, which was one of the most successful and enjoyable in the history of the society. Dr. John M. Thomas, president of State College, newly elected president of the society, officiated as toastmaster. Dr. Thomas gave a brief address in which he outlined the history of the work done by engineers in bringing the world to its present state of prosperity and predicted that engineering work will have an important bearing on the industrial future of the world. George E. Stevenson, retiring president of the society, introduced Dr. Thomas in an impressive talk. The speaker of the evening was Dexter S. Kimball, dean of the school of engineering at Cornell University and past president of the American Society of Mechanical Engineers. Mr. Kimball's address was interesting and instructive. Peter G. Rimmer, of Wilkes-Barre, was chairman of the banquet committee.

Somerset County coal output is to be increased by extensive improvements in the Garrett section. The Tri-State Colliers Coal Mining Co. producing 1,000 tons daily, has equipped the mine with electricity. The operation in Moshannon vein owned by Charles Merrill as well as that of the Moore, Courtney & Furtney Co. has also been electrified. A new development in the Moshannon vein is being opened by the George Stein Coal Co.

A. J. Musser, general manager of the Clearfield Bituminous Coal Corporation, has by action of the board of directors been appointed vice-president and general manager in charge of the property and operations of the corporation with headquarters at Indiana.

General Manager J. B. Warriner, of the **Lehigh Coal & Navigation Co.**, in an open letter to taxpayers and others in the Panther Creek region, calls attention to the fact that local taxation—that is school, borough and county taxes—has increased 383 per cent since 1913, as far as this company is concerned. In 1913 the total was $191,000. In 1922 it will be approximately $923,000. These figures do not include the anthracite tonnage tax, which will amount to about $500,000 a year on navigation output, nor do they include any other state or federal tax. In a general way, it might be said, purely local taxation is costing about 25c a ton on the total navigation production. In 1921 the local taxes mounted to $473,000. "The big jump in 1922," says the letter "is due to the action of the Schuylkill County Commissioners, who have assessed coal lands at from five to ten times their actual value, or at the rate of 500 to 1,000 per cent, while private property has been assessed at from 8 to 50 per cent of its actual value. During the period 1913-1922 wages have increased approximately 137 per cent; the cost of living, according to the government index, has risen 55.6 per cent; while taxes have increased 383 per cent. Every cent for taxes unjustly or unnecessarily levied is a blow at the anthracite industry. The results inevitably will be low wages or curtailed working time, which is the same thing. When this time comes it will be too late to remedy the situation—the mine worker will suffer, not the politician."

Robert Holiday, superintendent of the Crucible mine of the Crucible Fuel Co., at Crucible, has resigned his position.

Charles Enzian, consulting electrical engineer, of Philadelphia, has accepted a position as chief engineer of the Berwind-White Coal Mining Co., at Windber, succeeding **James Browning**, who has been appointed as general superintendent.

The Triple Vein Coal Co., owned by Charles F. Roy, and Robert Roy, both of Somerset, and H. P. Wood, engineer, of New York, is equipping the Southside mine, on the Casselman River at Garrett, with a **belt conveyor and picking table combined**, the work being under supervision of Engineer H. P. Wood. A double crossing also is being placed at the pit mouths. The improvements will enable the company to load coal at both the Baltimore & Ohio and the Maryland R.R. sidings. The improvement will increase the daily tonnage to 1,000 tons.

UTAH

The I. C. C. has given the Carbon County Railroad Co. permission **to build 4.79 miles of railroad** from a junction on the Sunnyside branch of the D. & R. G. Ry. to the coal deposits of the Utah Coal & Coke Co., which are to be developed by the Columbia Steel Co. The cost of construction, without equipment, is estimated at $293,902. This includes $56,459 for tipple yards. The equipment is expected to cost $50,000. Construction is expected to be completed by May 1, 1923.

According to the U. S. Bureau of Mines, **more coal is being mined under government leases in Utah than in any other state** in the Union. Out of the forty-four coal leases thus far made by the government, fifteen are in Utah

At this writing **the fate of the Utah Public Utilities Commission seems to be in the balance.** Two or three lively hearings have been held by the legislative committee in charge of the bill to repeal the law, establishing the commission. One witness stated that since the commission was created in 1917 it has saved the people of Utah $3,000,000 in refusing carriers' advances in freight rates.

VIRGINIA

The Fall Branch Coal Corporation, of Johnson City, Tenn., which was lately incorporated for $20,000, has 300 acres of coal land under development at Splashdam, with a daily capacity of 200 tons.

The Fairfield Coal Corporation, of Wise, has been incorporated with a capital of $10,000. S. U. Hyman, of Keystone, W. Va., is president of the corporation and Max Kaplan, of Wise, Va., is secretary.

The Old Dominion Coal, Iron & Coke Co., of Roanoke, has increased its capital to $200,000. J. N. Newton, Jr., is president of the concern.

WEST VIRGINIA

The Ideal Coal Co., of Charleston, has been incorporated with a capital of $150,000. The incorporators are S. L. Walker, G. L. Guthrie and A. S. Jenkins.

The Independent Coal Co., of Huntington, has increased its capital stock to $100,000.

The capital stock of the **National Coal Mining Co.**, of Charleston, has been increased from $50,000 to $150,000.

The Jack Run Coal Co., of Clarksburg, has been incorporated with a capital of $60,000 and with Lugi Ridolfi, of Barracksville, and William D. Aurorea and Z. Ridolfi, of Clarksburg, as the incorporators.

The Mountain State Coal & Gas Syndicate has been formed at Huntington, to take over the Williams Sanatarium at Kenova, the Gracum Coal Co. and the Cabell Oil & Gas Co., of West Virginia, and the Mud River Co. and the Stevenson Coal Co. of Kentucky. The company is capitalized at $2,000,000 and has elected the following officers: President, **Thomas W. Jones**, of Middleport, Ohio; secretary, E. W. Bush, of Huntington, W. Va.; treasurer, T. J. Kennedy, of Huntington, W. Va.

The Monongah Fuel Co., of Monongah, of which David Victor is president and general manager, has awarded the contract for the installation of electrical equipment to the Fairmont Electric Service Co., at Fairmont. The improvements will consist of three transformers, motor generator set, a switch, lightning arrester,, steel substation tower and miscellaneous switchboard and protective apparatus.

An announcement just given out at the headquarters in Indianapolis, Ind., of the United Mine Workers of America that **a compromise** has been reached in the damage suit of the **Willis Branch Coal Co.** of West Virginia against the Mine Workers, was **"unfounded and unauthorized,"** according to John L. Lewis, international president. Mr. Lewis said that the extensive nature of this litigation has required numerous conferences between counsel for both sides and that "the entire subject matter is still in the hands of the attorneys."

Negotiations are reported to be in progress by Henry Ford for the **purchase of the coal interests of T. E. Houston** in Mingo and McDowell Counties, according to reports here, which local operators assert are reliable. The main offices of the Houston interests are in Cincinnati. The properties constitute the second largest coal operations in southern West Virginia. Those involved in the reported negotiations are: Houston Coal Co., Maitland mine, Maitland; King Coal Co., King Mine, Kimball; Tidewater Coal & Coke Co., Tidewater No. 1 and No. 2 mine, at Vivian; Houston Collieries Co., Carswell No. 1 and No. 2 mines at Kimball; Keystone Coal & Coke Co., Keystone Mine, Keystone; Houston Coal & Coke Co., Houston mines Nos. 1, 2 and 9, at Elkhorn; Thacker Coal & Coke Co., Thacker mines Nos. 3, 9, 11, 12, 15 and 18, at Thacker.

Probable purchase of the Virginia Ry. by Henry Ford continues to be a topic of absorbing interest in coal circles. The understanding is that Mr. Ford would like to obtain possession of this road in order to make Norfolk a terminal for all shipments to Europe and South America.

To the 103 mines now operating on the Virginian Ry. is soon to be added that of the **Morrison Coal Co., which will ship about 50,000 tons a month.** The company has under lease a total of about 4,600 acres on Laurel Fork of the Guyan River in the Wyoming County field. The Morrison Coal Company is one of the group in which the Laings are interested. Some coal is already being mined and stored at the source of production pending completion of a spur of five miles from the main line of the Virginian, which is to be ready about May 1. In the meantime work is boing forward on the tipples and within the next six weeks work will be begun on the construction of houses. The plants of the new company will be of the most modern type and every convenience and comfort will be provided for the workmen.

The Virginian Ry. enjoys the distinction of having the largest wreck-train crane in use on any railroad in the world. It is a 200-ton crane and was built especially to handle the big moguls operated by that railroad.

The Bell Creek By-Product Coal Co. has been incorporated, the capital stock of the company being fixed at $50,000. Montgomery is given as the general headquarters of the company. Incorporators of the new concern are J. E. Wilkinson, F. E. Smart, W. H. Koester, G. C. Humphreys, C. N. Smithson and W. H. Thomas, all of Montgomery.

The Logan County Coal Corporation, just organized, represents a consolidation of several companies in the Logan field in which the same people were interested, the effect of the merger being to combine all the companies under one management. The concerns consolidated were the **Lundale Coal Co., the Three Forks Coal Co., the Amherst Fuel Co.** and several subsidiaries. The combined capitalization of all the companies is in the neighborhood of $1,000,000. With all the companies under one management it is estimated that it will be possible to reach a production of 2,000,000 tons a year. Officers of the Logan County Coal Corporation are: George M. Jones, president; J. N. Schweitzer, vice president; Angus MacDonald, of Charleston, secretary; W. R. Foglesong, Jr., assistant secretary; F. P. Chambers, treasurer; W. W. Beddow, general superintendent; J. B. Kirkpatrick, purchasing agent; R. C. Newman, auditor. The company will have its general office at Lundale.

Receipt of a check for taxes of the **Consolidation Coal Co.** in Marion County, discloses that that company is the largest taxpayer in the county. In Marion County alone the Consolidation company paid a total of $114,000 in taxes.

The Kuhn Coal & Mining Co. has executed a lease to A. M. Sigmon, F. W. Kuhn and D. C. Breedlove covering a seam of coal known as the Peerless Gas on Witchers Creek for a period of five years. The lessees will be required to pay a royalty of 50c. a ton on all coal mined. Failure to operate the mine for a period of 80 days will serve to invalidate the lease.

WISCONSIN

H. H. Morris has been appointed district manager of the Cincinnati office of **the Valley Coal Co.**, Milwaukee, Wis., and also will handle the purchase of coal from mines in the States of West Virginia and Kentucky. **R. E. Olmstead** has been appointed field agent of the company, with headquarters in Huntington, W. Va.

The Chippewa Lumber & Coal Co. has been incorporated at Chippewa Falls with a capital of $70,000; incorporators: W. A. King, H. T. King and T. A. Willenbockel.

Alex B. Uhrig was elected to the presidency of the **Milwaukee-Western Fuel Co.**, made vacant by the death of his father, Edward A. Uhrig, in December.

CANADA

The Spokane & Alberta Coal & Coke Co., of which L. K. Armstrong, of Spokane, Wash., is general manager, **is opening up coal lands in the Crow's Nest Pass district.** A considerable expenditure already has been made on development and it is planned to begin shipping coal some time this winter. The Canadian Pacific Ry. has given permission for the linking of the company's three-mile spur with the main line of the Crow's Nest Pass Ry., and the work is in progress.

In an address given at a luncheon held at Drumheller, Alta., in honor of Sir Henry Thornton, president of the Canadian National Railways, Ltd., J. Gouge, vice-president of the Western Canadian Coal Operators' Association, advocated the **elimination of the Canadian import duty of 53c. a ton on lignite**. This duty, he said, afforded no protection to the Canadian lignite industry, but on the contrary adversely affected it in its efforts to become established in the Western States. The United States, it was pointed out, exacts a duty on coal only from countries imposing an import duty on that commodity. To Sir Henry Thornton, it was suggested, that Alberta coal might be established in the Ontario market if through coal trains were provided at much reduced rates.

The executive committee of the United Mine Workers, District No. 26, Glace Bay, N. S., has decided **to abide by the ruling of the International Executive Board** that the application of the district for permission to affiliate with the Red International of Moscow be withdrawn. It was decided to appeal to the next International convention of the United Mine Workers.

The property of the old Diamond Coal Co. near Lethbridge, Alta., is getting a new lease on life under the management of the **Consolidated Diamond Collieries**, which is now operating three slopes in the 5,000-acre tract controlled by the new company, and **will soon sink a shaft and begin a development of the property to raise its output from about 800 tons a day to 2,000 tons.** J. L. Parker, of Burmis, who formerly was with the Diamond Coal Co., becomes general superintendent of the Consolidated company's operations in February. Melvin Jackson, managing director, has been on a trip through the mining regions of the East and Middle West in the United States buying machinery and equipment.

Association Activities

Logan Operators' Association

Charles W. Jones, president of the Merrill Coal Co., was elected president of the Logan Operators' Association at its annual meeting held in Huntington on Feb. 3. Other officers chosen were: Frank Enslow, Huntington, first vice-president; A. J. King, Huntington, second vice-president, and H. A. McAllister, treasurer. The executive committee consists of President Jones, A. R. Beisel, H. E. Jones, G. M. Jones, R. R. Smith, W. R. Thurmond, C. H. Jenkins and M. E. Kent.

Following a discussion it was decided to ask the Chesapeake & Ohio Railroad Co. officials to improve the transportation facilities from the Logan field. The association was asked to extend its aid to the establishment of a hospital for crippled children which it is proposed to erect at Huntington. A banquet followed the meeting.

Winding Gulf Operators' Association

The Winding Gulf Operators' Association held a meeting at White Sulphur Springs on Feb. 3, when transportation facilities on the Virginian Ry. were discussed, shippers at the meeting seeking to ascertain just what they might expect from the Virginian in the future. There were representatives of 103 mines present at the meeting. S. M. Adsit, traffic manager of the road, declared that although the Virginian was handicapped by a lack of adequate motive power the road had succeeded in handling 1,000 more cars of coal during January than during any corresponding month in its history. The management of the road has ordered fifteen new locomotives of the large type, some of which will be available by May and all of them by July 1. The road will soon receive bids from two of the larger electrical manufacturing companies for the electrification of the road from Elmore, W. Va., to Roanoke, Va.

As a result of a discussion of mine rating and distribution, a committee of two was named to meet with like committees from each coal district on the line of the Chesapeake & Ohio for the consideration of new rules affecting the allotment of coal mines. The association also went on record in favor of the construction of a hard surface road from Beckley to Mullens.

Morgantown Wholesale Coal Association

The Morgantown Wholesale Coal Association at a recent meeting held in Morgantown named the following officers for this year: R. R. McFall, of the Southern Fuel Co., president; F. M. Lucas, of the Stentz-Lucas Coal Co., vice-president; W. M. Powell, of the Southern Fuel Co., treasurer; Paul H. Keener, of the Metro Coal Co., secretary; C. E. Watson, of the C. E. Watson Coal Co., secretary of the board of directors. It was decided by the association to hold a meeting every Tuesday and that at every meeting a program of interest to the coal industry should be arranged for. The speaker at the first meeting held in accordance with such a plan was C. M. Lyons, of the Equitable Coal Co., whose subject was business ethics as applied to the coal industry.

Traffic News

In taking exception to the tentative opinion in the Western coal rate case, the Sheridan-Wyoming Coal Co., the Big Horn Collieries Co. and the Owl Creek Coal Mining Co. declare that "in order to give all Western coal an opportunity to compete, **differentials, in cases where they are necessary, should be made as small as possible.**" They make a plea for definiteness in these differentials so that there will be no uncertainty in the future and that they have the right to demand rates on fine coal to any destination to which the carriers carry fine coal rates from competing points of origin.

The Kemmerer-Rock Springs operators urge the Commission to prescribe **a differential of 85c. for southern Wyoming** under Castle Gate to the Northwest and permit the Union Pacific to establish the Castle Gate basis of rates from southern Wyoming to Salt Lake City or, as the irreducible minimum, to prescribe a differential of 75c. to the Northwest and permit the Union Pacific to establish the Castle Gate basis of rates from southern Wyoming to Salt Lake City.

Extension of the Tennessee, Alabama & Georgia Ry. Co.'s tracks from Gadsden to Odenville, Ala., has been approved by the Interstate Commerce Commission. This extension will afford transportation to a coal and iron region.

In an effort to meet the shortage of domestic fuel in the South, the Interstate Commerce Commission on Feb. 9 issued Service Order 38, which probably will be followed by similar orders, instructing the Southern Railway Co. **to assign fifteen cars per working day** to the mine of the Montevallo company at Aldrich, Ala. The order is to be in effect until March 5. It provides, however, that not more than 20 per cent of the amount shipped on any day is to be sold for use for other than domestic purposes. The cars assigned under this order are not to be counted against the distributive share of the mine.

After an extended study of the coal rates involved in the case of **Dewey Brothers Co. vs. the Norfolk & Western Ry.**, A. S. Worthington, an Interstate Commerce Commission examiner, has submitted a tentative opinion stating that the commission should find that **rates on coal** in carloads from inner crescent mines served by the Chesapeake & Ohio, Louisville & Nashville, and Norfolk & Western to Blanchester, Leesburg, and Lynchburg, Ohio, **were unreasonable** to the extent that they exceed $1.70 per ton prior to Aug. 26, 1920, and $2.38 thereafter, and that like rates from inner crescent mines on the C. & O. and L. & O. to Lynchburg are unreasonable to the extent that they exceed $2.38 per ton.

He also states that the commission should find that the **rates on coal from outer crescent mines on the N. & W.** to Blanchester, Leesburg and Lynchburg **were unreasonable** to the extent that they exceeded $1.80 per ton prior to Aug. 26, 1920, and $2.48 thereafter. As the present rates, with the exception of the rate to Lynchburg, from points on the C. & O. and L. & N. are in conformity with the proposed conclusion no order with respect thereto is necessary.

Rates on coal from mines on the Norfolk & Western in the Pocahontas, Kenova, Thacker and Clinch Valley districts to stations on the Norfolk & Western and connecting branches between Roanoke and Bristol are found to be **not unreasonable.** In its opinion to that effect the Interstate Commerce Commission dismisses the complaint brought by the Mathieson Alkali Works at Saltville, Va.

An unreasonable rate was charged the Hoosier Lime Co. for the transportation of 55 cars of coal from Victoria and Midland, Ind., to Salem, Ind., in the opinion of the Interstate Commerce Commission's examiner who handled the case. In his tentative report he recommends the payment of reparation.

Charges collected on coal from the Globe Iron Co.'s mine to its furnace at Jackson, Ohio, were not unreasonable, in the opinion of the Interstate Commerce Commission's examiner who handled the case. He recommends that the complaint be dismissed.

Obituary

The death, on Jan. 24, of **David Cochrane,** the inventor, designer and first builder of the open feed water heater which bears his name, closes the career of a man whose ideas have resulted in the conservation of millions of tons of coal per annum in the United States and elsewhere. Mr. Cochrane was born in Sawkey, Clackmanmonshire, Scotland, in 1850, and in his early years worked as a patternmaker on the Clyde. In 1879 he came to the United States. His open heater, brought out in 1883, was specifically designed to protect boilers from the effects of cold, unpurified feed water and was itself the first to be built of cast iron plates, to avoid corrosion. Mr. Cochrane also was the first to design a successful oil separator, a heater and receiver, and other appliances which have since become standard practice.

Abraham Carpenter Overholt, aged 65 years, died at his home in Scottdale, Pa., on Jan. 31, after several weeks' illness. He was vice-president of the Lincoln Coal & Coke Co., director of the East Fayette Coal Co. and the Woodland Coal Co., all with offices in Scottdale. Mr. Overholt also was vice-president and a director of the First National Bank and a director of the Scottdale Savings & Trust Co. He was the founder of the United States Cast Iron Pipe & Foundry Co. at Scottdale and at one time was its president.

William C. Goodnow, 57, for many years connected with the coal trade in Minneapolis, died Jan. 28, following an operation. With his brother, the late John Goodnow, (afterwards consul-general to Shanghai, China) he engaged in the retail business in 1893. In 1909 he formed the W. C. Goodnow Coal Co., wholesale, with offices in the Lumber Exchange, which he continued until his death. He was a 33d degree Mason, and was active in club life. Interment was at Hannibal, Mo.

Coming Meetings

The Rocky Mountain Coal Mining Institute will hold its winter meeting Feb. 24-26 in Denver, Colo. Secretary, Benedict Shubart, Boston Building, Denver, Colo.

American Institute of Mining and Metallurgical Engineers will hold its annual meeting Feb. 19-22, 1923, at the Engineering Societies Building, New York City. Secretary, F. F. Sharpless, New York City.

International Chamber of Commerce will hold its second general meeting in Rome, Italy, March 19-26.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

National Foreign Trade Council will hold its annual conference April 25-27 at New Orleans, La.

Northwestern Pennsylvania Coal Operators' Association will hold its annual meeting March 6 at the William Penn Hotel, Pittsburgh, Pa. Secretary, T. F. Diefenderfer, Butler, Pa.

Canadian Institute of Mining and Metallurgy's annual meeting will be held March 7, 8 and 9 at the Mount Royal Hotel, Montreal, Quebec, Canada. Secretary, George C. Mackenzie, Montreal, Quebec, Canada.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., Dec. 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

Indiana Bituminous Coal Operators' Association will hold its annual meeting March 14 at Terre Haute, Ind. Secretary, P. H. Penna, Terre Haute, Ind.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

Southern Appalachian Coal Operators' Association will hold its annual meeting Feb. 23 at Knoxville, Tenn. Secretary, R. E. Howe, Knoxville, Tenn.

The executive board of the **Coal Mining Institute of America** will meet in Pittsburgh, Pa., Saturday, March 3.

The Gas and Fuel Section of the American Chemical Society is arranging a second sectional meeting at the New Haven meeting of the American Chemical Society during the first week in April. The section program will consist of papers on gas and fuel chemistry and a symposium on motor fuels, held jointly with the petroleum division.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, THURSDAY, FEBRUARY 22, 1923 Number 8

Shades of George Baer!

IT IS a commonplace to designate certain among the labor side as radicals and thus to indicate they are disposed to turn things upside down, to destroy the present order of things and make the world over. The complacent majority always is more or less tolerant of the antics of the "reds" providing they are not too militant, the more philosophical probably conceding that it is healthful to be stirred to thought at times.

The ultra conservative and the radical are so far apart that they come together, as when East meets West. The ultra conservative lives in the past and has learned nothing of the present. It is but a step from his way of doing things to the way the radical would have them done. If we decry the radical, we must deplore the ultra conservative. If we would take issue with the element—it happens to be in labor—that would abolish capital and despoil the public for its own selfish ends, we also must take issue with the element—it happens to be in capital—that would override the rights of all others.

We are as disposed to dub the coal operator a radical who has no respect for the public or the rights of his fellow operators as we are the labor unionist who wants to take over the coal mines. The coal operator who is so steeped in his own ego that he consistently refuses such a measure of co-operation in an emergency as has been deemed reasonable by his fellow operators is as dangerous to the public welfare and the peace and good repute of the coal industry as any who wave the red flag. On his head rests more responsibility for unrest, suspicion and public condemnation than upon all the acts of all others combined. A policy of the "public be damned" no longer sets will in this country.

It is an unfortunate weakness in the present order of things that a whole group must appear to condone, if indeed it is not held equally at fault, for the policy of wilful obstinacy of one of its number. There is no means of discipline. There is but disappointment and chagrin that an otherwise good record of responsible coal operators for sensible, reasonable co-operation with the government should be marred by one of their number.

Canada's Share of Available Anthracite

MATTERS of fact and matters of policy are involved in the present controversy over the anthracite shortage in New York and New England and the embargo on shipments to Canada demanded by certain spokesmen from that territory. The matter of policy is easily and quickly disposed of. To all intents and purposes Canada is a part of the United States so far as coal is concerned. This question was threshed out during the war as well as in the 1919 strike, and Canada was treated as one of the states of our Union. Canada is entitled to her pro-rata share of our coal conditioned upon her following the same sort and degree of restrictions over its use and distribution as are imposed on this side. Happily it appears that this is the last word of the administration at Washington, for we are informed that no embargo will be imposed.

As regards the facts there remain some doubt, for we have not the complete story of anthracite distribution this year, the Hudson Coal Co., reputed to be a large shipper to Canada, having refused, according to the Federal Fuel Distributor, to divulge any data with respect to what it has done with its coal. But aside from the fact of whether that company shipped all its coal to Canada or none, there remains the fact that the communities in trouble are not asking for coal but are demanding anthracite.

The short supply of hard coal for householders has been pieced out this winter by millions of tons of substitutes, mainly soft coal. Those who accepted the situation and are using a reasonable share of other fuel are not making complaints to Congress. New England is sore over the coal situation. The Pennsylvania state tax, the strike, and now high prices at the curb and dirty coal, and not enough of it, have riled a people beset by an unusually hard winter. This has given opportunity for political play, and it also has given opportunity for spreading some sound truths about coal and the use thereof.

Kicking against the hard fact that a 60-per cent supply will not fill a 100-per cent requirement takes many angles.

Modern Silesian Mining Methods

SO MUCH has been said about German flushing methods that our readers will be much interested to find from the article by A. Gerke in this issue that the Silesian mine owners are not maintaining those methods but are tending toward systems such as we are following, that do not include flushing as part of the process.

The war seems to have changed the attitude of the Silesian coal operators so that they prefer to run the risk of losing a little coal to the unpleasant certainty that large sums of money would have to be spent should they fill their mines with waste rock and washer tailings. Whether we are justified in continuing our methods in the face of our waning anthracite supplies and lack of virgin coal territory is a matter that must, and will be, decided in the end upon other premises than German precedent, but the methods described by Mr. Gerke will be held by many to be a proof that the flushing method is expensive and justifiable only where the conservation of small quantities of coal and the protection of the surface are of more importance than conservation of labor.

The stockwork system described by Mr. Gerke is almost, or entirely, unknown in American coal mines. It is a suggestion nevertheless for those who operate beds on heavy pitches.

Recent Disasters and Their Lessons

REGRETTABLE indeed have been the recent explosions at Spangler, Dolomite, Dawson and Dunsmuir. It is to be hoped that their lessons will not be forgotten and that from them will come improvements in practice that will make explosions far less frequent. Of the Spangler and Dunsmuir explosions nothing will be said here. It is better to discuss only the other two, which were obviously and admittedly accidents resulting from coal dust.

Both occurred in mines which were admirably managed, but it would seem that in both too much confidence was shown in sprinkling, and here it should be conceded that in both mines the word "sprinkling" seems inadequate to express the volume of water actually used. "Dousing" with water would appear more appropriate. J. J. Forbes tells us in this issue that in Dolomite ten men were employed solely in keeping down coal dust. He assures us that the work of these men saved many lives, and we can well believe him.

Nevertheless, the Dolomite disaster was a coal-dust explosion, and it would appear that the sprinkling that was so efficient to the inbye of the main parting could not have been so effectual outbye from that point and possibly in the parting itself. It appears that runaway cars had raised a heavy dust on other occasions, and so it was undoubtedly present at least most of the time. No evil result had followed from this dust, and doubtless none was anticipated. No shot was likely to be placed at this point, consequently none could blow out, and the dust of coal is not readily fired unless the flame is part of the gust by which the dust is raised. If it were not so, probably many a tipple would long ago have been demolished by an explosion, for the air in such places always is charged heavily with dust.

Unfortunately there was always the possibility of a short-circuit either of the trolley wire or of the high-potential feeder. So when the opportunity came the dust was there and the explosion occurred. It is certain that the accident would not have happened had the feeder been trenched and covered by a plank, as are the high-voltage feeders in the Valier mine of Illinois. Furthermore, there were the trolley wires always ready to act in the same rôle as the offending feeder line, should the cars travel so far before piling up.

For this reason it is necessary to call attention to the danger of the mine entrance. It was at this point that the Monongah explosion started, killing 361 men. Here it was the trolley wire that made the short-circuit. Again in the Starkville mine of Colorado it was not far from the mouth of the mine that the explosion started, and it was a wrecked trip of cars that was the initiating cause. The explosion traveled several miles into the interior of the mine, and all the men—there were 56 of them—who were at work were killed.

So much attention has been given to the dangers of the live workings that those of the entrance of the mine have been overlooked. Yet in the mines of northern climes this is the one point which, in many cases, may not be properly safeguarded. If well sprinkled with water it will soon be rendered impassible because of the formation of ice. Here all the air receives its first warming, and here it is most greedy for moisture. Consequently this is the point where rock dust is greatly needed.

We cannot doubt that the European practice of "stone dusting" or rock dusting, as we term it, is the safest method, especially where the cars are not allowed to leak or spill coal. It is said that a company in the Middle West long ago lost faith in sprinkling and is a strong advocate of rock-dust barriers. Undoubtedly traps like these are good, but a general dusting everywhere is even better, and the use of both is better yet.

Obviously neither the Dolomite nor the Dawson workings constitute a safe mine, for contingencies might arise and have arisen in them causing explosions. The large sums expended, the rigorous inspections, the elaborate system of prevention, the intelligence of the management, were alike admirable but ineffectual. Let us hope there is something better. Let us trust that where the company has the personal integrity of the Woodward Iron Co. and the Phelps Dodge Corporation they can make their mines foolproof and rascal-proof. But that can be done only by pursuing some other method than that now adopted.

At the Dawson mine there has been one accident already from a blownout shot, and the recent disaster possibly may prove to have had a similar origin. It is true that when the company's rules have been followed there is no danger that an explosion will result from the firing of shots. It is clear that in such a climate as New Mexico a mine that is free from explosions of any kind for years and never has had them when shooting coal according to rule must have a good schedule of operation and must have a splendid body of shotfirers to carry it out.

Where explosives are allowed to come into a camp, however, they may be stolen. That may occur either before or after their distribution, and if a single man can steal a single cartridge and fire a single unauthorized shot and that shot will explode the mine, the system, though admirably conceived and carefully carried out by all the personnel but that one man, is a failure, and some means should be taken, if possible, to correct it.

It must be remembered that the greater the crime of firing an unauthorized shot the more likely it is to be a menace to everyone in the mine when it does occur. No man violating a law so needful to be enforced, the punishment of which, if detected, is so sure, will take the time and use the patience to make the shot safe. He in all probability will tamp it with coal dust as the material most readily at hand.

It is extremely difficult to wet coal or any other dust through and through. The top may be wet and the bottom still dry. The dust also will float unwetted on the water. Forceful spraying is necessary and not always successful. For this reason the use of rock dust is the safer remedy and should have had greater acceptance long ago.

This country invented the rock-dust spraying machine. Let it not be the last country to put it in continuous operation. Since Great Britain and France have compelled the use of rock dust and required the inspectors to ascertain, by sampling, the dusts on the mine floor, conditions have much improved. If the rule is not everywhere needed, as in the anthracite region, it surely is indicated in sections where the conditions are arid, where the hygrometer shows the percentage of moisture present in the air to be unduly low and where accidents like those at Dawson and Dolomite prove that the danger is unusually imminent.

WHAT THE COUNTRY NEEDS is more railroading and less railriding.—*Norfolk Virginian-Pilot.*

ON THE OTHER HAND, if it is going to be impossible to get coal there is still a lot of discarded political timber available.—*Detroit News.*

How Greater Depth and Reduced Thickness of Coal Have Intensified Lackawanna Mine Problems

Coal Is 71 Per Cent as Thick and 17 Per Cent Deeper Than Fifty Years Ago—Depth and Thickness by Five-Year Periods—Increased Use of Power Raises Output per Mule

By Dever C. Ashmead*
Kingston, Pa.

IN LACKAWANNA COUNTY, Pennsylvania, the average depth at which anthracite is mined increased from 229 ft. in 1872 to 268 ft. in 1922. The average thickness of bed mined, 6.83 ft. in 1872, in 1922 was but 4.88 ft. That hard-coal mining is getting deeper each year and that the thicker beds are being mined out has been a matter of common knowledge for years. This study, it is believed, is the first attempt to set forth these important facts in a quantitative manner. The results of this investigation, representing a year's collection and study of all available data, are not startling to those familiar with the hard-coal regions of Pennsylvania but they are illuminating to those who have wondered why the cost of their household fuel has been mounting year after year.

Prospect of Future Even Less Assuring

That the cream of the anthracite deposits has been removed and that from now on we must depend on an output from deeper and thinner beds, costing each year more and more in man power for its production, means only that the cost will continue to mount and that the total output cannot in any considerable degree pass that of recent years.

Conditions vary from district to district in the anthracite area and the results of this study will be presented in a series, the first covering the Lackawanna district, embracing the mines in Lackawanna County, Susquehanna County and Wayne County. At the conclusion of the articles on the several fields the data will be summarized for the whole region, with a forecast on costs in the immediate future.

The writer desires to express his thanks to R. V. Norris, consulting mining engineer, of Wilkes-Barre, for his advice and assistance in the preparation of this series of articles. To the Department of Mines of the State of Pennsylvania particular credit is due for the collection of data on depth and thickness, obtained by the mine inspectors from the various coal companies at the request of the writer. Thanks also are tendered to the office force of the Department of mines at Harrisburg for their aid in compiling statistics not published in their annual reports.

The representative character of the statistics on which this study is based is indicated by the following table and diagram (Fig. 1) showing against the total operation in the district the number of plants from which figures were obtained. In 1921-22 approximately 96 per cent of the companies reported on the depth and thickness of the beds. In 1902 about 95 per cent reported. In 1887 there were reports from about 61 per cent and 49 per cent reported in 1872. It was possible to use 85 per cent of the production statistics for 1921, 92 per cent for 1902 and 54 per cent for 1877.

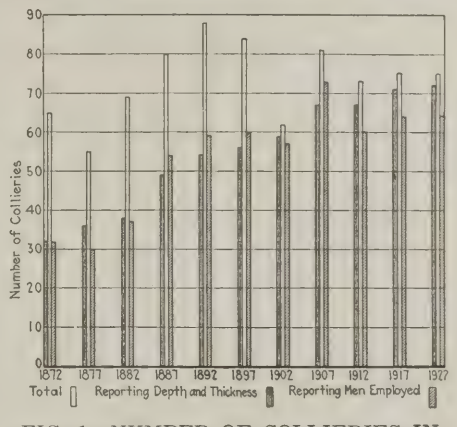

FIG. 1—NUMBER OF COLLIERIES IN LACKAWANNA COUNTY

This diagram shows the number of plants from which statistics on depth and thickness of coal mined were available by year and the number from which data was secured with respect to men employed, as compared with the total.

Washery coal and strippings have been excluded from the calculations wherever possible. Collieries known to sell locally likewise have been omitted. The geologic series in the Lackawanna district, as shown in Fig. 2, lies comparatively flat. The beds of coal are at shallow depths. The principal beds worked in the region are as follows, named from the surface down: Eight Foot, Five Foot, Four Foot, Diamond, Rock, Big Vein, New

*Assistant Editor, *Coal Age*.

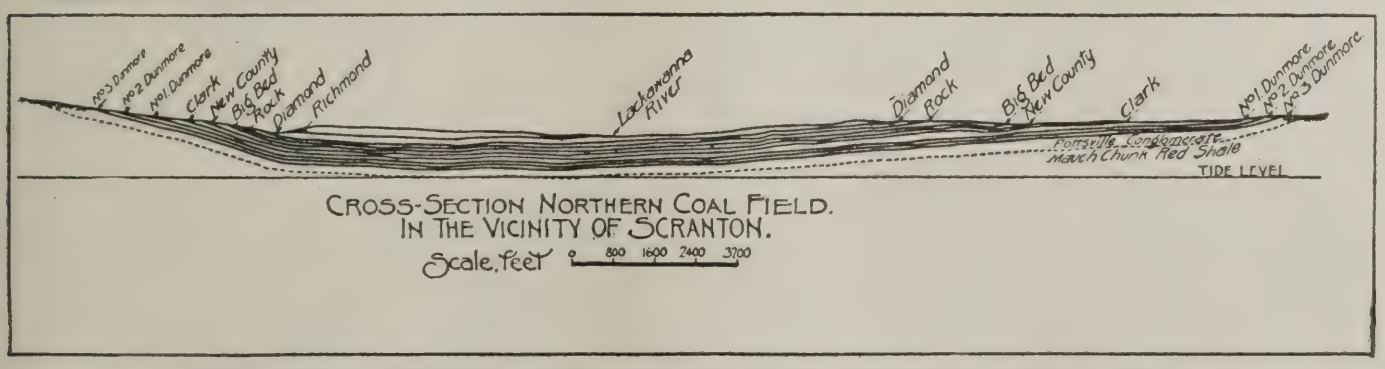

FIG. 2—SECTION OF THE LACKAWANNA DISTRICT IN THE VICINITY OF SCRANTON

This section of the coal measures shows the general flatness of the beds in this vicinity. It will be noted that the beds become slightly pitching as they approach the outcrop. Locally there are heavy rolls or faults. Even in the center of the basin the beds of coal are not flat but pitch heavily in small areas.

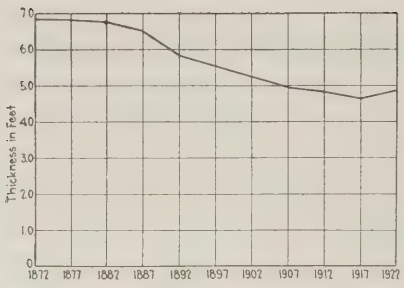

FIG. 3—AVERAGE THICKNESS OF COAL MINED AT FIVE-YEAR INTERVALS IN THE LACKAWANNA DISTRICT

The points on this curve were calculated from data obtained by the Department of Mines of the State of Pennsylvania from the various coal companies. A simple average thickness of coal was determined for each colliery, as there are no records of the output by beds. These simple average thicknesses were then multiplied by the production of the colliery and the results from all of the collieries were totaled. This total was divided by the total production of the collieries considered and the result plotted as weighted average thickness of the beds of coal in the Lackawanna district. This method was followed for each of the years shown.

County, Clarke, First Dunmore, Second Dunmore, Third Dunmore. In the vicinity of Forest City, at the northeastern end of the district, only the four lower beds are worked, but passing to the southwest to the Lackawanna-Luzerne County line the measures become deeper and here the higher beds are mined. From 1872, when the supply of anthracite was considered to be practically inexhaustible, the price was low and only the cream of the deposits were mined, and until 1882 there was no marked change in mining conditions. The average thickness of the beds mined in 1882 was 6.78 ft., compared with 6.83 ft. in 1872. From the early 80's on there was a steady depletion of the thicker beds and by 1917 the average thickness had decreased to 4.65 ft., or a drop of 31.8 per cent. The slight increase in thickness shown for 1922 over 1917 was due primarily to the opening of small outcrop strippings which could not be separated from the rest of the data.

Although the present average thickness is estimated at 4.88 ft., this does not tell the true tale. The coal that is now being obtained from the thicker beds is a continually decreasing percentage of the total output, as the work in these measures is now mainly second mining and in some cases third and fourth mining. In 1872 79.5 per cent of the coal was taken from beds thicker than the average for 1922. In 1872 only 20.5 per cent of the coal came from beds thinner than 5 ft., and of this 20.5 per cent, 14 per cent was from beds between 4 and 5 ft. in thickness and only 6.5 per cent from beds from 3 to 4 ft. thick.

Beds less than 3 ft. thick were first mined in 1887 and then represented only 1 per cent of the total. By 1922 25 per cent of the total was from beds thinner than 3 ft.

Fig. 3 shows that from 1897 to 1917 there were one or two beds being mined whose thickness averaged between 1 and 2 ft., but in 1922 there was no mining in beds of this thickness. These beds probably were found to be unprofitable or else they have been exhausted. However, even now in a few cases mining is being done in beds thinner than 2 ft., but only for very small local areas in

TABLE I—NUMBER OF COLLIERIES IN LACKAWANNA COUNTY

	Total As Reported by the Department of Mines	Having Depth and Thickness, Data	Having Tonnage Data
1872	65	32	32
1877	55	36	30
1882	69	38	37
1887	80	49	54
1892	88	54	59
1897	84	56	60
1902	62	59	57
1907	81	67	73
1912	73	67	60
1917	75	71	64
1921–2	75	72	64

TABLE II—AVERAGE DEPTH AND THICKNESS OF COAL MINED IN THE LACKAWANNA DISTRICT, IN FEET

Years	Average Depth of Workings	Average Thickness Of Beds	Years	Average Depth of Workings	Average Thickness Of Beds
1872	229	6.83	1902	276	5.28
1877	240	6.83	1907	275	4.94
1882	265	6.78	1912	278	4.84
1887	254	6.53	1917	266	4.65
1892	264	5.88	1922	268	4.88
1897	281	5.55			

a bed which averages a greater thickness. Sometimes it is necessary to remove this coal to get at the thicker coal in the same bed. It is clear from this record that the thicker beds are being worked out and that the production of coal in the Lackawanna district may be kept up only by mining more extensively the thinner beds.

Because the beds of coal in the Lackawanna district lie practically flat there are no marked variations in the depths of the workings. In 1872 the average depth of workings was 229 ft. (Fig. 5) and in 1897 this depth reached the maximum of 281 ft. Since then the average depth has not varied more than 15 ft. This may be explained by the fact that the thinner beds of coal which have been opened up in more recent years are scattered through the measures at both shallow and deep levels.

Even though the average depth of workings has remained fairly constant since 1897, the maximum depth of workings has increased. Until 1892 there were no workings reported deeper than 600 ft., but since then the lowest workings have gone deeper and deeper. The maximum depth in 1897 was 800 ft.; in 1902 it was 900 ft. and in 1907, 1,000 ft., the record for the Lackawanna district. In the meantime there has been an increase in the percentage of workings that are less than 100 ft. in depth, for in 1922 about 19 per cent of the workings were within 100 ft. of the surface and this has counterbalanced the greater maximum depth and kept the general average constant. It is interesting to study the change in the thickness of the beds at various depths of workings. This is shown in Fig. 7. Here the average thickness of beds is shown for every 100 ft. change in the depth of the workings. The main feature brought out here is that quite generally throughout this district, irrespective of depth, the thickness of the beds worked has decreased since 1872 and that the average thickness of the beds in the different levels has remained relatively constant.

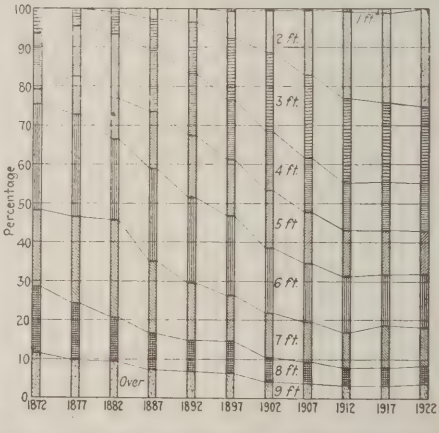

FIG. 4—PERCENTAGE DISTRIBUTION OF NUMBER OF BEDS WORKED BY THICKNESS IN THE LACKAWANNA DISTRICT

This diagram shows the percentage of the total number of beds of each thickness mined in each year. How, as the region has been developed, thinner and thinner coal beds have been opened up is clearly shown in this diagram. The information on which this diagram is based was furnished by the Pennsylvania State Department of Mines from data supplied by the mining companies.

In the early days of anthracite mining mechanical power was not used in the production of coal. It was not until about 1848 that the first steam engine was used, and it was installed in a breaker to drive the rolls

and the revolving screens of that day. There were a few hoisting and Cornish pumping engines used, but most of the mines were opened by tunnels or drifts, so that very little power was required. Even in the fifties comparatively little power was used and it was not until 1860 that steam power was greatly used about the mines. In 1872 although power was being used it had not reached its maximum, for many operations that are now done mechanically were then done by hand.

The increasing consumption of power required in the production of anthracite is shown in Fig. 8. Previous to 1897 there was little or no mechanical underground haulage with the exception of rope haulage. The power necessary to operate the breakers was small, for in 1877 the coal smaller than chestnut was left underground in some mines. The coal coming from the thicker beds was comparatively clean and was given but little preparation other than crushing and screening. The individual plants were small. Less power was required to hoist the coal to the surface from the shallower depths of those early days. There were fewer surface breaks and the surface water did not have access to the mines through the cave holes.

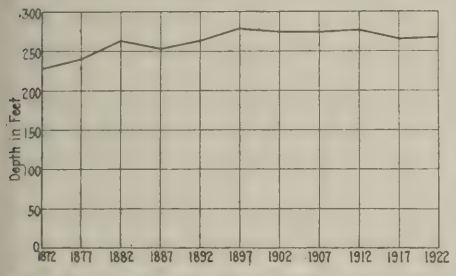

FIG. 5—DIAGRAM SHOWING THE INCREASING DEPTH AT WHICH ANTHRACITE HAS BEEN MINED IN THE LACKAWANNA DISTRICT FROM 1872 TO 1922

The data on which this diagram is based were supplied by the mining companies at the request of the Department of Mines of the State of Pennsylvania. Reports were made showing the maximum depth of workings on each bed in each mine at five-year intervals from 1872 to date. The simple average depth of workings as thus reported was first determined for each colliery. The average of all was determined by weighing each by the production of that colliery as shown by the records of the Pennsylvania State Department of Mines. It was impossible to obtain a true weighted average depth of workings because records of production by beds are not available save for recent years. The Lackawanna district does not show the increase in depth of workings that is found in other regions to the south. From 229 ft. in 1872 to around 270 ft. in the past thirty years is but a small increase.

For the years 1877 to 1897 inclusive it was possible to produce more than 1.5 tons of coal for every boiler horsepower installed, and a trifle under 1.5 tons of coal for each engine horsepower installed. Since then, however, the amount of coal produced per boiler horsepower and engine horsepower installed has uniformly decreased and in 1917 there was produced only 0.82 ton of coal per boiler horsepower and 0.62 ton per engine horsepower.

The increasing use of fuel coal per ton of production follows from a number of factors. It may be expected to increase in the future.

The proportion of total output raised through single shafts is increasing, and therefore larger and quicker operating hoists are required. Mechanical haulage underground is gaining, requiring more power. Greater quantities of water are being raised because the more extensive openings and the surface breakthroughs permit the entrance of the surface water into the mines. At some mines the amount of water that has to be handled is stupendous, reaching at one colliery about 90 tons to each ton of coal shipped.

The mining of thinner beds, many of which are dirty; waste material from shooting down the roof or taking up the bottom to provide sufficient headroom and the working of beds which contain heavy partings formerly considered worthless are all factors requiring more careful preparation of the coal so that it can be marketed. This additional preparation calls for more power. The tendency of all these factors is in the direction of greater and greater power requirements in the mining and preparation of anthracite.

TABLE III—POWER USED IN PRODUCTION OF ANTHRACITE IN THE LACKAWANNA DISTRICT

Years	Boiler Horsepower Installed	Engine Horsepower Installed	Tons of Coal Hauled per Mule	Tons of Coal Produced per Boiler Horsepower	Tons of Coal Produced per Engine Horsepower	Number of Underground Locomotives per 100,000 Tons of Annual Production
1877	13,860	13,931	18.0	1.77	1.76	....
1882	17,610	18,746	12.7	1.51	1.42	....
1887	25,770	27,897	14.9	1.58	1.46	....
1892	33,000	25,443	17.3	1.74	2.10	....
1897	50,000	.....	21.8	1.72	....	....
1902	56,435	68,464	19.6	1.38	1.14	0.19
1907	91,560	98,864	21.8	1.06	0.99	0.74
1912	106,684	112,977	24.4	0.84	0.80	1.37
1917	86,417	114,186	27.6	0.82	0.62	2.18

It is doubted whether the length of underground haul in the anthracite mines has materially increased in the past fifteen years. It is probable that the length of haul increased materially from 1872 to 1882. The length of haul appears to have reached a maximum in 1882, for the tons of coal hauled per mule per day were the least in 1882. From 1882 to 1897 the amount of coal hauled per mule per day increased with shorter haul. From the time (1897) when the underground mine locomotive first began to take on a share of the haulage work, the use of the mule fell off.

The mounting curve of number of underground locomotives considered with the increased tonnage per mule per day brings out the fact that when motors are installed the mule's travels are shortened and more tons are handled each day per animal.

The first serious subsidence of the surface in the anthracite region was reported in 1865 at Stockton, in the Eastern Middle field. A home and a family of five

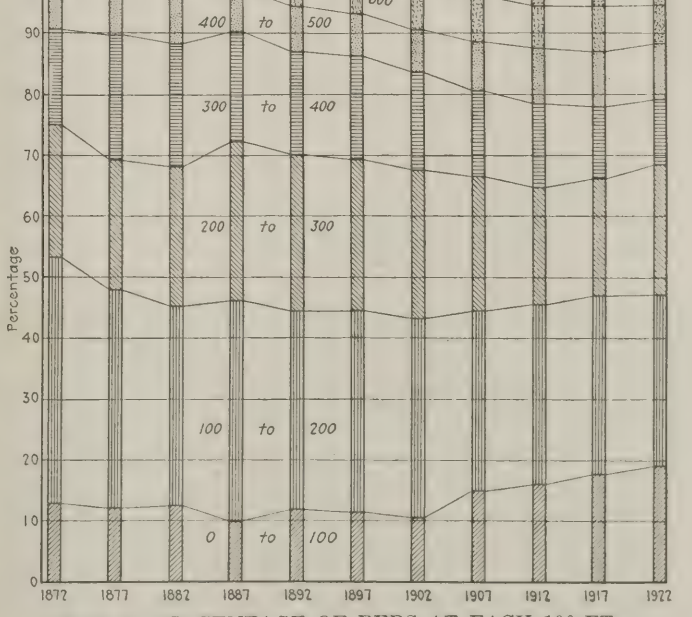

FIG. 6—PERCENTAGE OF BEDS AT EACH 100-FT. INTERVAL OF DEPTH

This curve shows the percentage of beds being worked at each 100-ft. level. The maximum depth only is shown. A bed may be worked at a maximum depth of 500 ft. and be worked at each 100-ft. level upward to the surface, but is here recorded at the maximum depth. The numbers of beds worked each year and at each 100-ft. interval in depth were counted and the percentages to the total plotted on this curve.

were engulfed and their bodies were never recovered. Almost yearly since then more and more support of the surface is removed and there are numerous cases of settlement. This is particularly true of the Lackawanna district, where the beds are closer to the surface than they are elsewhere in the region. The City of Scranton itself has suffered greatly in this respect. Subsidence must be guarded against in built-up areas or if not guarded against then the property so damaged usually is restored. In either case money must be expended and the cost of production increased.

Man power is indispensable in mining coal. Men are required to direct machines and machinery and to do work that can be done only by hand. Many of the labor-saving devices used in other kinds of mining cannot be used in anthracite operations. This is largely because of the character and attitude of the coal beds. The efficiency of the man power determines to a large extent the cost of mining coal. If in the whole region it is found that the efficiency of the men is decreasing it is interesting to seek the explanation.

Production of Coal Per Total Employee

In Fig. 10 three sets of curves are shown. The lower one shows the average output of coal per day for all men employed as calculated from the mine inspectors' reports. A small loss in average daily output, all employees considered, is indicated from 1872 to the later dates. This is in face of the fact that new and improved types of machinery have been developed, reducing the man power required to do the work.

The decrease in output per man employed is greater, however, than is shown by the solid line on Fig. 10. In the earlier years the small sizes of coal were not sold or shipped and were not recorded as production. That is, the divisor in calculating average tons per man was too small. Corrections in the figures that take into account the total output in the earlier years give the dash-line curve in Fig. 10. This indicates a fairly regular decrease in the average output per man, from a maximum of 2.84 tons per day in 1877 to 1.74 tons per day in 1921, a decrease of approximately 39 per cent.

TABLE IV—MULES AND LOCOMOTIVES IN MINES IN THE LACKAWANNA DISTRICT

	Mules In Service	Inside Locomotives		Mules in Service	Inside Locomotives
1877.....	1,361	...	1902.....	3,976	45
1882.....	2,089	...	1907.....	4,472	217
1887.....	2,727	...	1912.....	3,862	369
1892.....	3,321	...	1917.....	2,566	466
1897.....	3,950	...			

FIG. 7—AVERAGE THICKNESS OF BEDS AT EACH 100-FT. INTERVAL IN THE LACKAWANNA DISTRICT, 1872 TO 1922

The points on these curves were calculated from data furnished by the various mining companies to the State Department of Mines. The figures are unweighted averages as there are no records over this period covering the tonnage of coal produced from each bed.

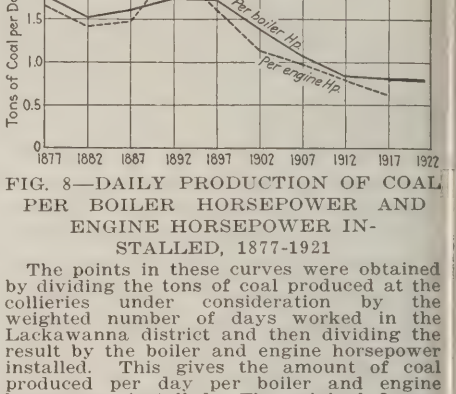

FIG. 8—DAILY PRODUCTION OF COAL PER BOILER HORSEPOWER AND ENGINE HORSEPOWER INSTALLED, 1877-1921

The points in these curves were obtained by dividing the tons of coal produced at the collieries under consideration by the weighted number of days worked in the Lackawanna district and then dividing the result by the boiler and engine horsepower installed. This gives the amount of coal produced per day per boiler and engine horsepower installed. The original figures for these calculations were obtained from the reports of the mine inspectors to the Pennsylvania State Department of Mines. In the earlier years no figures of boiler horsepower were recorded but from the details of the size of the boilers the capacity was calculated.

A further correction is necessary. There have been two changes in the length of the standard day. From 1877 to 1902 the day was 10 hours, and from 1902 to 1916 it was 9 hours. Since 1916 it has been 8 hours. Seemingly, therefore, the dash-line curve should be corrected by reducing the figures by 20 per cent for the years 1877 to 1902, and by 11 per cent from 1902 to 1916 to bring all records to the comparable basis of 8 hours per day. However, from information in old reports and from conversations with superintendents of the earlier years, the writer concludes that the miners never worked longer hours than they do at the present time, particularly the contract miners. These corrections are made, therefore, only with respect to day men. The final corrected figure is 2.55 tons of coal per man per day in 1877 as against 1.74 tons in 1921, a decrease in average daily production of 0.79 ton of coal per man employed, or 31.2 per cent.

The second set of curves in Fig. 10 shows the average daily output per inside employee. The heavy line shows, as calculated from the mine inspectors' reports, an output in 1877 of 2.95 tons compared with 2.32 tons in 1921, a decrease of 0.63 ton per man per day, or 24.8 per cent. Corrected for the smaller sizes not shipped in the earlier years, the figure for 1877 is 4.33 tons per man per day, some two tons, or 46.4 per cent, above 1921.

From 1902 on there is little variation in the average daily outputs for inside employees. There is some evidence that these daily averages went up in 1917 and 1918. Figures from the records of a few companies employing about 4,000 miners show that these men worked on an average of about 0.4 hour more during the war period than they did in 1919. This reported working time for the year 1918 at these few mines was 7.

hours at the face and in 1919, 7.1 hours at the face. Taking this into consideration, the curve, even during the latter period, shows a decided decrease in the tons of coal produced per day per inside employee.

The third and last set of curves in Fig. 10 shows the average daily output of outside employee. The showing here is controlled by the changes in breaker employees. During the early period there was comparatively little machinery used in the breakers, as the coal was clean and required a minimum of preparation other than that given by the breaker boys. There were many men and boys assigned to this hand preparation, which reduced the average daily output of outside employees. From 1872 to 1877 for the first time the average output decreased. During the late seventies jigs were introduced in this region, and gradually the slate pickers decreased and the tonnage per man increased. Gradually the capacity of the breaker machinery was increased and as it increased the output expanded. No more men were required to man the breakers with larger capacities than were required to operate the older and smaller ones. With the introduction of conveyor lines and the more extensive use of steam locomotives and other mechanical devices for moving the coal below and on the surface there has been some decrease in the number of men required. As against this it is probable that a few more surface men are now required to handle and prepare timber to support the continually increasing areas of new mining opened underground.

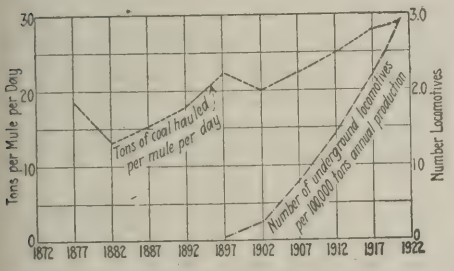

FIG. 9—AVERAGE DAILY TONNAGE HAULED PER MULE AND NUMBER OF UNDERGROUND LOCOMOTIVES PER 100,000 TONS OF ANNUAL PRODUCTION, IN THE LACKAWANNA DISTRICT

These figures were calculated from the reports of the district mine inspectors of the Department of Mines of Pennsylvania. In determining the tons of coal hauled per mule per day, the total production was divided by the weighted number of days worked in the Lackawanna district and then by the number of mules at the corresponding collieries. The number of locomotives per 100,000 tons of coal produced was determined by dividing the number of tons of coal produced by the weighted number of days worked for the district, multiplying the result by 300 (as a full working year) to bring the figures to a common base. This result was divided into the number of locomotives used in the district, and by pointing off properly the result is the number of locomotives per 100,000 tons of coal produced. It will be noted that the figure for 1897 of tons of coal per mule per day is extremely high. This is due, it is believed, to errors in the inspectors' reports for that year. This divergence will be noted in many of the curves for the year 1897.

The increase in power required has meant in some cases an increase in the force used in producing power, but as against this the mechanical stokers have cut the force. Then again other companies have ceased producing their own power wholly or in part. The introduction of electric machinery has added electricians to the outside forces.

Again noting the data shown in Fig. 10 it is seen that in 1877 the average daily output per outside employee was 5.73 tons compared with 5.01 tons in 1882 and 8.03 tons in 1921, an increase of 3.02 tons, or about 60 per cent in 44 years. Corrected for the small sizes, the figures become 8.40 tons in 1877, 6.84 tons in 1882, and 8.03 tons in 1921. The correction here is for the full difference in the hours worked, as the men are mostly day men and although there are many monthly men employed there are no contract men. Therefore the cor-

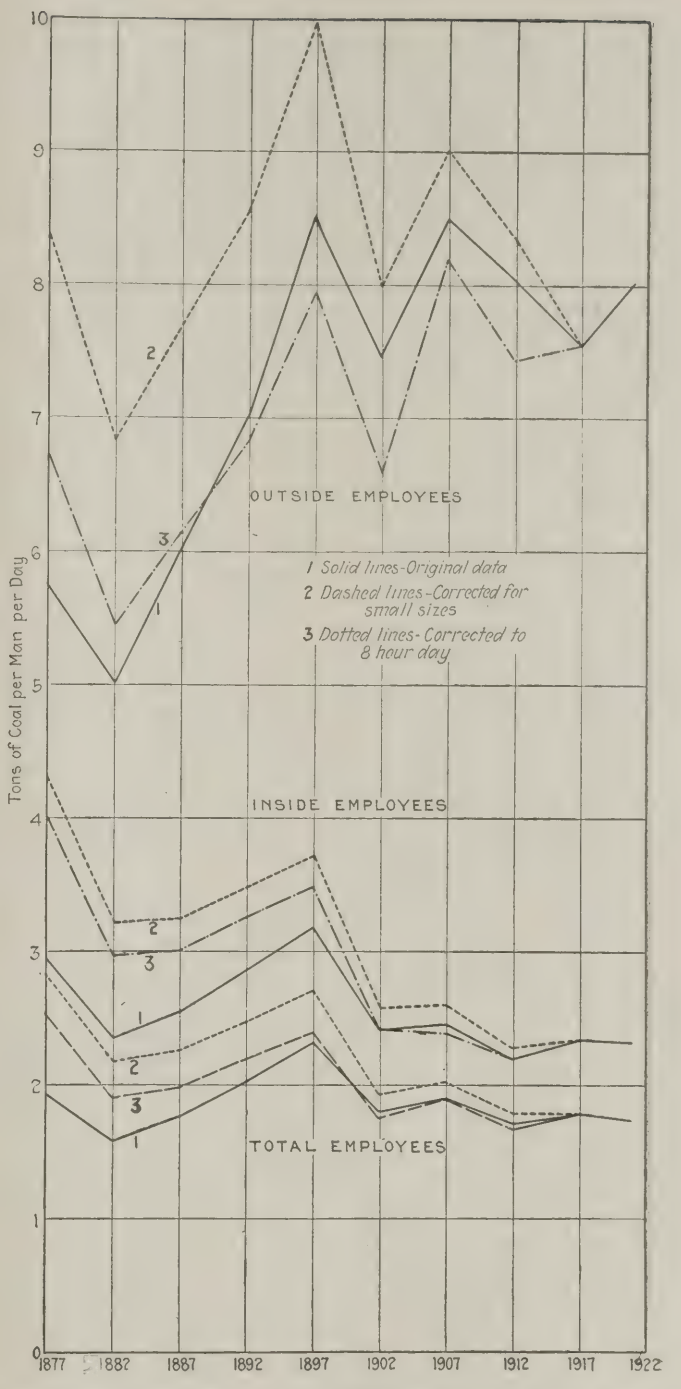

FIG. 10—AVERAGE DAILY PRODUCTION OF COAL PER EMPLOYEE IN THE LACKAWANNA DISTRICT, 1872-1921

The figures are shown as calculated from the reports of the state mine inspectors, also with corrections for small sizes of coal not reported as production in the earlier days, and finally to a uniform 8-hour day. The solid lines represent the figures as calculated from the original data taken from the reports of the mine inspectors in the anthracite region of the Department of Mines of the State of Pennsylvania. The days worked were determined by multiplying the number of employees by the number of breaker days at each colliery. Then the total number of employees in the district was divided into the sum of the men-days at each colliery and the result considered the weighted average number of days worked. The next step was to divide the total number of employees into the total production of the collieries to determine the average annual output per employee. This, divided by the weighted number of days worked, gave the average daily output per employee.

The dash line shows the correction for small sizes. It was impossible to obtain exact tonnages of small sizes of fresh mined coal shipped in these earlier years but from information in the reports of the Girard Estate and in the Coal Trade Annual estimates were made. For later years the actual figures are given by the U. S. Geological Survey. These estimates are: 1872, sizes under chestnut shipped, 8.8 per cent; 1877, 16 per cent; 1882, 26.8 per cent; 1887, 30 per cent; 1892, 42 per cent; 1897, 57 per cent; 1902 82.7 per cent; 1907, 84.6 per cent; 1912, 90.3 per cent. Knowing the true percentages of small sizes produced, the corrections were made by difference from these estimates. As no washery coal is considered in these figures the percentage of small sizes from washeries was not taken into consideration.

rection is heavier than where the inside men are considered. The final corrected curve shows for 1877 an average daily output of 6.72 tons for outside men against 5.47 tons in 1882 and 8.03 tons in 1921.

Thus, although from 1877 to 1921 the average daily output for outside men increased, the increase has not been sufficient to counterbalance the loss in average daily production per inside employee, and the average daily production for all employees shows a decided decrease.

Until 1902 the mines operated ten hours a day, from Oct., 1902, to 1916 they operated nine hours a day and from 1916 to date the standard day has been eight hours. To reduce the figures of average daily output to a comparable basis it was necessary to correct for the differences in the length of day worked. The figures during the 10-hour day period were reduced by 20 per cent; for 1902 they were reduced 17.3 per cent, as the mines worked 10 hours for a few months at the beginning of the year and 9 hours at the end, and during the 9-hour day period the figures were reduced by 11 per cent. To allow for the fact, irrespective of the hours of the day men the time actually worked by the miners has always been about 8 hours, a further correction was necessary. The miners represent about 50 per cent of the total force and correction was made accordingly. It will be noted that the year 1897 is out of line with the others. This is believed to be due to errors in the mine inspectors' reports for that year. The diagram also shows these data, original and with the same corrections for inside employees.

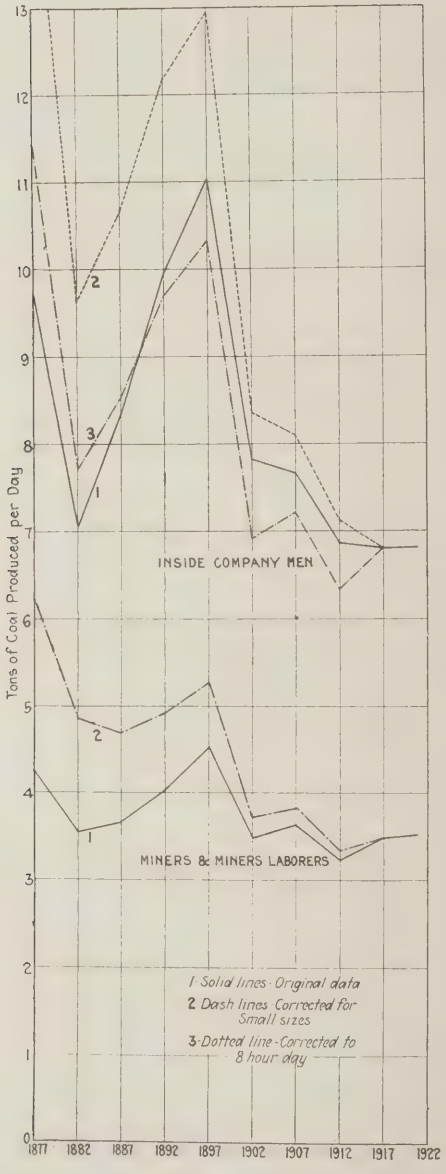

FIG. 11—AVERAGE DAILY PRODUCTION FOR INSIDE EMPLOYEES IN THE LACKAWANNA DISTRICT, 1872-1921

The figures are shown as calculated from the reports of the state mine inspectors, also with corrections for small sizes of coal not reported as production in the earlier days and finally to a uniform 8-hour day. In the calculation of these curves the same method was used as in calculating the curves for the number of tons of coal produced per day per total man employed. No correction was applied for hours worked for the miners, as they worked the same time under all conditions. It is again necessary to call attention to the fact that the points for the year 1897 are too high and should be neglected and that the average for the years 1892 and 1902 is considered to more nearly represent the facts.

TABLE V—MEN EMPLOYED IN PRODUCTION OF ANTHRACITES IN THE LACKAWANNA DISTRICT

	Total Employees	Inside Employees	Outside Employees	Miners and Miners' Laborers	Company Men
1872	9,655	6,744	2,911	4,818	1,926
1877	9,553	6,305	3,248	4,394	1,911
1882	13,084	8,892	4,192	5,910	2,982
1887	22,944	16,122	6,822	11,146	4,976
1892	25,649	18,212	7,437	12,930	3,321
1897	31,661	23,015	8,646	16,332	6,683
1902	30,941	23,379	7,562	16,177	7,202
1907	39,413	30,563	8,850	20,715	9,848
1912	42,859	33,385	9,105	22,705	10,680
1917	37,885	28,895	8,990	18,905	9,990
1921	34,644	26,888	7,756	17,748	9,140

Before considering the curve in Fig. 11, which shows a fairly uniform decrease in the daily output of underground men, let us see what has happened in the Lackawanna district that will throw light on this condition. The average thickness of the beds mined has been decreasing. Working thinner beds means that more cuts must be made across the face of the room or gangway and more holes must be drilled for a given output. The coal must be handled in cramped positions. Each of these conditions tends to reduce the daily output of the miner. In the thinner beds the top rock must be taken down or the bottom lifted to admit the mine cars. This deadwork reduces the productive work time of the miner.

In the mining of dirty beds the miners are required to devote a part of their time to the removal of the refuse underground. During the earlier days of mining the beds were practically clean and the time lost in the removal of refuse was negligible.

Another factor reducing the daily output of miners in some beds is supporting bad roof. Bad roof there always has been, but where the coal was thick in the old days 2 to 4 ft. was left for roof support. Coal is too valuable now to be left for this purpose. Setting timbers takes time and reduces the productive work time of the mine worker.

There are improvements in practice, however, that operate in the other direction. Machinery has been introduced, enabling the miner to get out more coal under the same conditions. In the Lackawanna district the beds of coal are flat and mining machines are extensively used in many of the mines for undercutting the coal. Scraper loaders are used in thin beds at many of the collieries, eliminating the hand loading into mine cars.

In the early period of mining the shotholes were drilled by hand, but now the jackhammer and similar types of drills are becoming common. Power drills reduce the labor of drilling and give the miner more time for loading coal and doing other work. Carbide and portable electric lamps have replaced the oil lamp. The miner has better light in which to work, without the smoke from the open flare. Good lighting is an important help to the underground worker.

Setting the increased difficulties in mining against the improvements in methods and machinery, it is interest-

TABLE VI—PRODUCTION AND DAYS WORKED AT ANTHRACITE MINES IN THE LACKAWANNA DISTRICT

(a) Percentage to inside employees

TABLE IX—AVERAGE DAILY PRODUCTION OF INSIDE MEN

Years	Miners and Miners' Laborers Reported	Miners and Miners' Laborers Corrected for Small Sizes	Inside Company Men Reported	Inside Company Men Corrected for Small Sizes	Inside Company Men Corrected to 8-Hour Day
1877	4.23	6.21	9.73	14.26	11.40
1882	3.55	4.85	7.04	9.62	7.70
1887	3.67	4.69	8.32	10.64	8.50
1892	4.03	4.91	9.97	12.16	9.72
1897	4.51	5.27	11.02	12.90	10.31
1902	3.48	3.74	7.82	8.36	6.91
1907	3.63	3.84	7.63	8.10	7.21
1912	3.73	3.35	6.86	7.13	6.35
1917	3.59	3.59	6.80	6.80	6.80
1921	3.51	3.51	6.81	6.81	6.81

the proper figure, then the dash curve shows a fairly uniform decrease in the amount of coal produced per miner and miner's laborer per day.

As has been previously explained, the figure for the miner's daily output should not be corrected for hours worked. However, in the earlier years the miner's laborer did not quit work with the miner and it may be possible that some correction should be made for this condition. It is not believed that such correction would affect the final result for in those days the number of miners' laborers was proportionately less than today. Furthermore, since the miners never did average 8 hours work per day, this would doubtless counterbalance the longer hours of their laborers.

The data for the earlier years on company employees probably is not as complete as it might be, but from 1882 on the figures are considered fairly good. The corrected figures for company employees (Fig. 11) from 1882 to 1892 show a gain in average daily output and from 1892 to 1921 they record a continuous decrease.

Why the greater output per man in the earlier period? During the earlier period the price of coal was extremely low and it is surmised that the companies forced to economize in some manner kept the number of company men at the lowest possible level. This increased the average daily output per man.

Motor haulage in this district began in 1895 and has continually increased, but there is shown no corresponding decrease in the number of men employed.

Electric Furnace for Determination of Coal-Ash Fusion Temperatures

By Osborn Monnett* and Jerome F. Kohout*

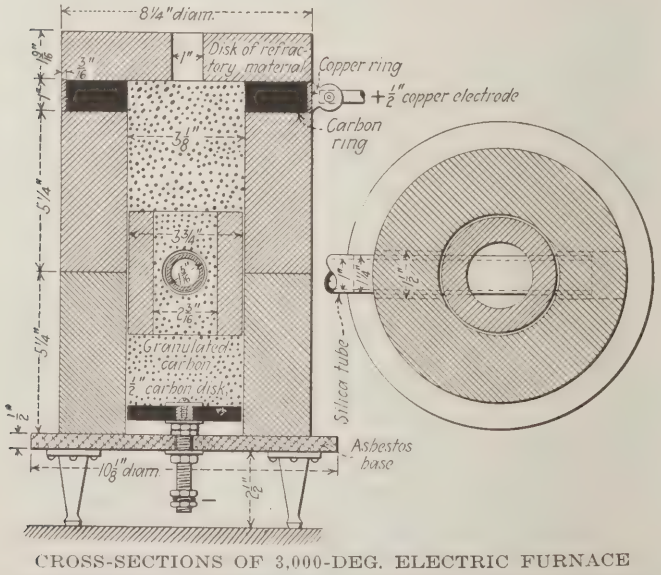
EXPERIENCE has proved the value of the electric furnace illustrated herewith for determining the temperature at which coal ash will fuse. It is of simple construction and economical in operation, and the fusing temperature of coal ash can be more quickly and easily found than in a gas furnace, which we regarded as undesirable because it was noisy in operation and too hot for the convenience of the operator and, furthermore, because temperatures approaching 3,000 deg. F. could not be attained without the introduction to the burners of auxiliary oxygen and because the atmosphere in the heated zone could not be regulated simply and positively.

Of prime importance is the character of the atmosphere in which the fusing takes place. The consensus of opinion at the present time is that the atmosphere should be such as will favor a minimum fusing temperature of the ash cone. With this form of electric furnace the proper atmosphere to ascertain that temperature can be introduced and kept under control.

The furnace we required was one in which the fusing would be done in a tube of about 1-in. bore. With the exception of the Hoskins tube furnace practically all the gas and electric furnaces on the market were of the crucible or vertical type or modifications of that construction. The Hoskins furnace, however, requires for its operation an alternating current of low voltage and high amperage. In consequence a transformer has to be used to provide current of the correct potential. We were limited to direct current of 110 or 220 volts and could not use over 35 amperes, owing to the restrictions imposed on those using the lighting circuit in the "Loop district" of Chicago.

The furnace as finally built consists of two refractory

*Commercial Testing & Engineering Co., Chicago, Ill.



cylinders, each 6 in. high, 8¼-in. outside and 3⅞-in. inside diameter, set on end, and one on the other. These form the outside of the jacket. The cylinders each have 1½-in. semicircular grooves made radially on one of their ends, on the bottom of the one and on the top of the other, so that when they are set up on each other with the grooves adjacent the jacket will have through it a hole 1¼ in. in diameter. Within these outer cylinders is another hollow cylinder also about 6 in. high, of 3¾-in. outside and 2 1/16-in. inside diameter, placed so that it is 3 in. below the upper edge of the upper cylinder and an equal distance above the lower edge of the lower cylinder. This inner lining is pierced at its mid length with a hole 1¼ in. in diameter which is placed so as to line up with the hole in the outer jacket.

A fused silica tube 8 in. long, of 1-in. bore and ⅛-in. wall is placed in this opening and forms the muffle. The heat is generated around the silica tube and within the inner refractory cylinder.

The electrode at the bottom of the furnace consists of a graphite disk 3¾ in. in diameter and ½ in. thick, through the center of which passes a ½-in. copper rod. The electrode at the top is a graphite ring of 3⅞-in. inside and 7-in. outside diameter and 1 in. thick. Around it is placed a copper band fastened to a ½-in. copper rod. Coarse granular resistor material is placed on the lower electrode in the lower cylinder.

The inner cylinder, carrying the silica tube, is placed in position, and the space around the tube filled with resistor material which has been ground so that all of it passes a 20-mesh and 60 per cent passes a 40-mesh sieve. The upper cylinder and upper electrode are placed in position and the rest of the furnace filled with the coarse granular carbon. The electrodes are connected to the line, and some sort of outside resistance is employed to control the current input and hence the temperature. A switchboard is used carrying resistance coils suitably connected to single-pole double-throw switches, so that any part or all the resistance may be cut out or put into series with the furnace.

The atmosphere is introduced through a small-bore silica tube placed in line with the muffle tube, so that the inner end of the small tube is within the inner end

CROSS-SECTIONS OF 3,000-DEG. ELECTRIC FURNACE

Substantially it consists of a two-piece vertical refractory cylinder made of Corundite, with an inner cylinder of the same character. Through these cylinders at right angle to them passes a silica tube which serves as the muffle. The furnace is mounted on a Transite asbestos base. Granulated carbon carries the current from the upper to the lower terminal, heating the silica tube in its passage.

ELECTRIC FURNACE AND ITS ELECTRIC CONTROLS

On the left may be seen the pyrometer for gaging the temperature. The control box above the desk is opened to show the switches, resistances and meters. This furnace is being operated by direct current.

of the larger. Illuminating gas in a slow stream is passed through absorption oil to remove whatever light oil or other hydrocarbons are soluble in it. It is then passed through water to saturate it with water vapor and then through a silica tube filled with pieces of coke and heated red hot.

The purpose of this hot tube is to break down the remaining hydrocarbons so that the gases leaving the tube are principally carbon monoxide, hydrogen, water vapor and nitrogen with a little methane. The gases next pass through a bunsen burner to mix in a little air, the upper end of the chimney of the burner being connected to the silica tube.

An analysis of the atmosphere within the silica tube drawn from the hot zone with the furnace at about 2,500 deg F. is as follows:

Gas	Percentage	Gas	Percentage
Carbon dioxide	9.5	Carbon monoxide	11.4
Unsaturated hydrocarbon	0.0	Methane	0.0
Oxygen	0.4	Nitrogen	71.5
Hydrogen	7.2	Total	100.0

A series of ash-fusion determinations was made on four samples of coal ash in this furnace, and the same ashes were fused in the gas furnace of the U. S. Bureau of Mines in its laboratory at Pittsburgh, Pa. One sample was fused in the Chicago Laboratory at 2,215 deg. F. and in the Pittsburgh Laboratory at 2,060 deg. A second sample fused at 2,361 deg. and 2,320 deg. respectively. A third sample fused at 2,555 and 2,500 deg. and a fourth at 2,892 deg. and 2,900 deg.

It will be noticed that the agreement is close, particularly in view of the fact that an operator making two determinations of the same ash in the same furnace is regarded as having checked his first figure if he comes within 90 deg. of that figure in making the second determination. In this case two different operators determined the fusing temperature with two totally different types of furnace, and yet the greatest difference between their results was 155 deg. F. For making temperature measurements a Leeds & Northrup optical pyrometer is used.

High-Power Cable Cut by Cars That Were Uncoupled In a Rotary Dump Explodes Coal Dust at Dolomite

Review of Accident Based on Intimate and Painstaking Inquiry—Injured Cable and Broken Car Wheel Found Suggestively Near One Another—Sprinkling, or Rather Dousing, of Workings and Spare Fan Saved Many Lives

By J. J. Forbes*

THE explosion which occurred about 2:40 p.m. Nov. 22, 1922, in the Dolomite No. 3 mine of the Woodward Iron Co., resulting in the death of ninety men and in slight or severe injuries to seventy or more others, was altogether unusual. Rarely do so many conditions combine to cause an explosion. It is believed that much greater loss of life would almost certainly have resulted if the Woodward Iron Co. had not employed means calculated to localize the effect of any explosion that might happen.

To enable the reader to understand the conditions under which the explosion occurred and was propagated a short description will be given of the mine layout. Dolomite Mines Nos. 1, 2, and 3 are all connected, but the ventilation of No. 1 mine is entirely separate from that of mines Nos. 2 and 3; in fact the last two mines are really one. No. 3 mine is opened by a slope driven on a pitch of 30 deg. through rock which at a distance of 850 ft. intersects the coal bed.

The slope, which is laid with two tracks, is about 6 ft. high and has an average width of about 20 ft. In line with the slope is the "yard," or parting, which has four tracks—two empty and two loaded. Its length is 500 ft. The "yard" is provided with a weighhouse, a motor pit, an office for officials, and other suitable conveniences. In the ordinary operation of the yard 12 to 20 employees, including couplers, spraggers, weighman, sandmen and sprinklers were employed. On the morning of the explosion 475 men were checked into No. 2 and No. 3 mines through No. 3 slope, and in addition to this 397 were checked into No. 1 mine, making a total of 872.

Spare Fan Ready for Just Such an Accident

The operation known as mines Nos. 2 and 3 is equipped with two separate and distinct fans, housed in fireproof buildings, one of which is provided for use in case of an emergency. At the time of the explosion the Capell fan, electrically driven, was in full operation. About 75 to 100 ft. therefrom is a Sirocco fan which by simply throwing in "jaw clutches" can be driven either by a gasoline motor or electricity. No. 2 fan pulled about 130,000 cu.ft. of air per minute, 70,000 to 75,000 cu.ft. of which entered through No. 3 slope, the rest intaking through slope No. 2.

All coal is loaded into wooden cars which are provided with tight gates and is transported from the live workings to the yard by ten electric locomotives. It is hoisted to the tipple by means of an electric hoist and is discharged into storage bins at that point by means of one of two 5-car rotary dumps. For the haulage of the coal ten electric locomotives are provided. Running along the right rib of the slope was a 3,300-volt armored protected cable. This feeder consisted of three conductors of No. 4 copper wire stranded, each covered with varnished cambric and separated by jute. Around the cable was about $\frac{1}{8}$-in. lead insulation and over the lead were two flat steel spirals $\frac{3}{4}$ in. wide wrapped so that one covered the spaces left by the other. The cable was guaranteed for 5,000 volts working pressure, according to a statement made at the coroner's inquest by W. M. Johnson, electrical superintendent for the company.

F. E. Dean, tipple foreman, testified at the inquest that the tail car in a trip of three empties jammed in the guides of the west rotary dump on the tipple. Chain blocks which were badly worn were first used by the tipple crew for pulling the trip, but without success. In an effort to release the car that was jammed the two front cars were disconnected and pulled forward for a short distance.

Broke a 60-Lb. Rail in Hurrying from Dump

The hoisting cable being disconnected, the cars ran backward with considerable momentum and dislodged the jammed car, breaking a 60-lb. rail that, to keep the cars from running away, had been placed across the riding ring of the dump about 2 ft. above the tipple rail and about 10 to 15 ft. below the jammed car. The cars started back into the slope running on the west track and as they neared the bottom they crossed over to the east side and were wrecked against some loaded cars that were standing in the yard.

W. M. Johnson testified at the coroner's inquest that after the explosion, but on the day on which it occurred, he had found a flattened place in the cable about 100 ft. from the foot of the slope and that this flattened place caused two of the three strands of wire to cross, forming a short-circuit. Johnson also stated that he found a broken car wheel about 15 ft. below the flattened place in the cable.

The Bureau of Mines' investigators had an opportunity to examine this cable during the coroner's inquest and afterward, and they observed the flattened place in the cable and the place at which the cable "blew" or arcked. It is believed that the cable was ruptured by a flying piece of steel, probably a car wheel from the wrecked trip, as there was no evidence that would indicate that the cable was ruptured by a car or cars running over it. It is said that whenever a trip broke loose from the tipple and wrecked in the yard it almost invariably threw clouds of coal dust into the air so dense that for some minutes it was difficult to see any considerable distance in the yard. Undoubtedly this wreck brought about the usual dense cloud of dust, and the short-circuiting of the cable with the arc thus resulting ignited the coal dust which was thrown into suspension when the cars piled up. F. E. Dean, tipple foreman, testified before the coroner's inquest that almost imme-

*U. S. Bureau of Mines.

diately after the trip was wrecked in the slope, particles of coal started to fly out of the mouth of the slope followed by flame.

On the afternoon of the explosion, as a result of the cessation of dumping in the tipple, about thirty employees had gathered on the yard, in addition to those regularly employed at that point. Among these were seven locomotive crews (three per crew), the foreman, the master mechanic, the machinist, the electrical workers, the transportation foreman, the sprinkler, and the assistant mine foreman.

The explosion wave worked inby, filling the yard with flame and killing practically everyone in the yard either by burns or gas, and also sent flame with considerable force out of the mouth of the slope, igniting such parts of the tipple superstructure as were of wood and this despite the fact that the building was located about 200 ft. from the portal of the slope.

It is reported by survivors who were on the tipple at the time of the explosion that there was much flame and that the smoke was so dense on the tipple that for some time no one could see what was transpiring. After leaving the yard the flame started into the haulage entries through openings which radiated therefrom. In the most of these haulageways the trolley lines were still found in place after the explosion and although few doors were blown out and brattices forced, the violence was not great, except possibly in the motor-generator room or substation where the flame found an abandoned drift in which the dust could gather.

Rescuers Without Apparatus Enter Mine

In a number of instances men rushed out of their working places upon hearing the blast and feeling the concussion and upon reaching the main aircourse, some met the gas which was being borne by the ventilating current toward the fan. Most of the miners who encountered the afterdamp retreated, and later on came out safely in fresh air after the currents had cleared the entries of afterdamp. Some of the men inhaled the poisonous gases that immediately followed the explosion and were rendered unconscious; especially was this true on the west side of the mine.

The fresh air quickly replaced the poisonous gases, however, and allowed rescuers without apparatus to pull unconscious men out of the gas pockets and to place them in fresh air where they might recuperate. Unfortunately a number of miners who were overcome by the first flow of poisonous gases did not recover and were found dead. In all, fifty-seven bodies were found in the yard, and twenty-nine bodies within several hundred feet of it, mostly along entries. Four died in the hospital, making a total of ninety dead.

The explosion was stopped within a few hundred feet of the yard owing to the efficient manner in which the mine workings had been sprinkled. In other words, due to the lack of dust for propagation, the explosion was localized and confined principally to the main entries and passageways leading from the yard of No. 3 slope. According to the statement of C. E. Nesbitt, chief state mine inspector, at the coroner's inquest, the mine was moist before the explosion, otherwise it would have extended throughout the mine workings.

The verdict of J. D. Russum, coroner of Jefferson County, Alabama, as to the cause of the Dolomite No. 3 mine explosion is as follows:

"After making a thorough investigation in reference to the 89 men* who lost their lives in the explosion of Dolomite No. 3 mine on Nov. 22, 1922, about 2:40 p.m. and after carefully studying the testimonies of all the witnesses which were practically in agreement, I find that the explosion was caused by the rupturing of a high-powered cable. After making a thorough investigation of said cable I find that the rupture was caused by a heavy blow from a flying piece of steel, possibly a broken car wheel, from a runaway trip of cars. I am unable to place the responsibility on any one individual, as the disaster was merely an accident."

Sprinkling lines traverse main and side entries, 4-in. and 2-in. pipe lines being employed for this purpose with taps usually placed at 100-ft. intervals. Common garden hose in 50-ft. sections is used for sprinkling both rooms and entries. A corps of ten sprinklers were continuously employed by the company to sprinkle the mine and they performed that task not only in the entries but in the rooms also. The rooms and entries are washed clean of dust, the work of thus sprinkling the entire mine taking approximately three days.

It is felt that a large number of lives were saved by the efficient method of sprinkling employed and a very disastrous explosion prevented which undoubtedly would have propagated into the workings of No. 2 and No. 3 mines and possibly into No. 1 mine. Again, it is believed that a large number of lives were saved by the commendable way in which the ventilation fans were arranged, for within 15 minutes after the explosion caused by the short-circuiting of the cable in No. 3 slope, the Sirocco fan, driven by a gasoline motor was in full operation, pulling full currents of fresh air through Nos. 2 and 3 slopes, thereby clearing the affected and unaffected parts of mines Nos. 2 and 3 of poisonous gases. The prompt starting of the gasoline fan after failure of that driven by electricity, whereby air currents were kept going at almost normal velocity, permitted the rescuers as well as the workers to travel in fresh air within a comparatively short time after the explosion.

*This verdict was given Dec. 15, 1922. Since that date one more man died in the hospital, making a total of 90 dead.

A Spanish Coal Field; the Wonder Is That It Was Not Worked Long Ago

DESCRIBING the Villablino coal field of Spain, H. M. Morgans, speaking before the South Staffordshire and Warwickshire Institute of Mining Engineers, said it measured $3\frac{3}{4}$x$17\frac{1}{2}$ miles. The coal beds are tilted steeply, mostly between 50 and 90 deg. parallel with the axis of a range of hills. Owing to the great pressure and movement the coal is tender. The range has been cut by half a dozen valleys running north and south at right angles to its axis. For this reason the coal seams can be worked by level driven on the strike from the sides of the valley or by cross-measure roads from the main east-and-west valley south of the range. There are nine to twelve seams, all over 20 in. thick. The total thickness is 36 ft. The interval between seams varies from 66 to 164 ft., and the character of the coal ranges from semi-bituminous to anthracite, with 20 per cent of volatile matter as a maximum. The ash content runs from 8 to 16 per cent, and heat values exceeding 14,000 B.t.u. have been obtained. The coal is mined by overhead stoping, working in steps and packing with dirt on which boards are placed to keep the coal clean. This packing partly comes from the mine but when needed is brought from outside.

Dispatching of Mine Cars at the Rolling Mill Mine

One Man Regulates from Telephone Center Entire Distribution of Cars Except in Night Shift and "Frogs" Sections Thus Providing Car Supply in Exact Proportion to Needs — Heading Trackage Covers 55 Miles

By George Atwell Richardson*

THE Rolling Mill Mine of the Cambria Steel Co., at Johnstown, Pa., which was opened more than sixty-seven years ago, has extended over a larger area than probably any other one mine in the United States. Its operations have covered approximately ten square miles. The distance to the farthest working face is five miles, and the total heading trackage actually in use aggregates about fifty-five miles. The record daily production of coal, made as recently as May 31, 1921, is 3,872 net tons.

At first glance figures such as these would suggest that the dispatching problems at this mine are of considerable magnitude and that the method of handling coal would be of a more or less complicated nature, involving much work and planning. As a matter of fact, however, the dispatching of trips is handled in a surprisingly simple manner with great efficiency, the details of which follow:

At the present time six sections of the mine are being worked. The sixth, or last, which is known as the "Mill Creek" area, is operated only on the night shift. Coal is hauled during the day from the other five sections, which are known as "Frogs," "Klondike," "4 Left," "6 Left" and "33 Level."

Dispatcher Allots Cars Among Motormen

The trips are controlled by one man who is known as the dispatcher. He has full control of the allotment of cars, running of trips, etc. He is located in a brick office (see Fig. 1) about one mile to the east of the main, or No. 26, sidetracks where the trips are made up. Close by the dispatcher's office is the head of an old three-track siding marking the end of the rope-haulage system which was abandoned only a comparatively short time ago. All gathering was done to this point. It is interesting to note that despite the age of the heading and its width, but little timber has had to be used for its support.

Coal is gathered by mules and storage-battery and electric locomotives. Mules are used where the gradient is so steep that the miners cannot push their cars from the working faces to the room necks. There are three mules in "6 Left" section and two in the Klondike. All the coal in the "Frogs" section is gathered by mules.

Storage-battery locomotives are used in certain locations owing to the presence of gas. Two are used on "33 Level," one on "4 Left," one on "6 Left" and one on "Klondike." All of these locomotives are rated as 7-ton machines. Cars are gathered in the Mill Creek section with trolley locomotives, for gas has never been found in that area. In fact for all purposes it is a separate mine.

For main haulage and for special purposes five 15-ton and three 10-ton trolley locomotives are provided. As a rule the hauling is done with one 15-ton and one 10-ton locomotive working in tandem. The normal trip averages about 80 cars, each holding about 1 ton 1,400 lb., but it is of record that one 15-ton locomotive hauled 103 cars over this grade.

The cars in use at the present time number about 1,000, of which 200 are allotted to the "Frogs" section. These latter are older cars, which can be used to advantage at this place because the haul is short.

The dispatcher's office is, of course, the nerve center of the mine and all mine telephones connect through it, and messages to the outside must be so routed during the daytime. At night a direct connection with the outside is maintained.

The present telephone system has three circuits and the three switches and the dispatcher's telephone can be clearly seen in Fig. 2. In all, connections are made to sixteen telephones. What these are is shown in the following table:

Switch No. 1 (Left in Fig. 2)	Switch No. 2 (Center in Fig. 2)
Outside Connections	
Supply Office	
Machine Shop	Frogs
Power house	Elk Run shaft
Foreman's office	Upper end, Elk Run siding
Switch No. 3 (Right in Fig. 2)	
No. 4 Left section	Bottom Mill Creek shaft (coal taken up here for boilers)
No. 33 level	No. 4 left side track (used mostly in bringing men out)
No. 6 left	Klondike
Mill Creek	No. 26 Siding
Pumproom	

The actual details of the dispatching are as follows: First in order comes the question of the proper distribution of cars. At "Frogs" that matter does not have to be considered, as the supply of cars will always take ample care of all the requirements of this section.

FIG. 1—EXTERIOR OF DISPATCHER'S OFFICE

The work of dispatching is based on a continuous record. The dispatcher knows just how many cars each section has received and can compare it with the number to which its capacity entitles it. In mines where dispatching is not checked by such a record injustices are likely to occur. Note the care with which the trolley wires are guarded.

*Midvale Steel & Ordnance Co., Cambria Steel Co.

NOTE—With the growth in size of modern coal-mining operations the problem of dispatching is rapidly becoming one of great importance to mine-operating officials. This is an account of the methods used in an operation which has been described in other articles in *Coal Age* by the same author.

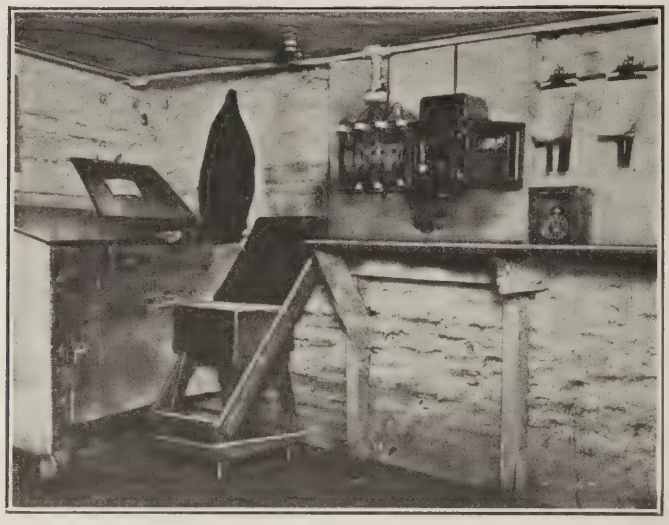


FIG. 2—INTERIOR OF DISPATCHER'S OFFICE
Here is the central station for sixteen telephones in various parts of the mine. The dispatcher arranges from this office for an even distribution of the cars at all points.

As a result the dispatcher pays no attention to it other than to get a record at the end of the day of the total number of cars loaded and hauled from these workings to the Elk Run shaft.

In the other sections a shortage of cars might often occur. The manner in which they are distributed to the different working faces depends entirely on the dispatcher's judgment based on his knowledge of the track system, the coal supply and other conditions.

All cars are distributed to these sections by gathering locomotives working to and from No. 26 sidetrack. The switch boy at this point attends to the telephone, the dispatcher giving him orders as to the number of cars to be allotted to each locomotive.

Outgoing trips operate on approximately 45-minute schedules, subject to the dispatcher's orders. A simple record is kept of these, which, however, meets all the present requirements. It consists of nothing more than a form ruled in pencil and filled out each day as shown, the record for Dec. 15, 1922, being taken as a typical example:

RECORD OF CAR APPORTIONMENT, DEC. 15, 1922

Trip No.	Frogs	Klondike No. Cars	4-Left Cars	6-Left Cars	33-Level Cars	Cars Per Trip from 26 Sidetrack	Time Net	Output Tons
1	..	24	30	..	15	69	8	194
2	..	22	27	23	31	103	9	336
3	..	26	32	23	22	103	10	512
4	..	26	33	25	33	117	11	763
5	..	20	32	28	33	113	12	1,070
6	..	23	32	27	..	82	1	1,300
7	..	30	32	24	33	119	2	1,441
8	..	23	29	31	33	116	3	1,680
9	..	22	32	32	33	119	4	1,925
10	..	21	..	24	31	76	5	2,347
Totals		237	279	237	264	1,017		

As is evident, the totals shown in the last column are cumulative. The final total and also that for total cars shipped includes cars from the "Frogs" section.

The night shift works only in the Mill Creek section and when it is through in the morning a pencil memorandum showing trips handled, cars loaded and hauled, and cars left for day hauling, is available for the dispatcher's use in planning his work.

Coal from the Rolling Mill mine is hauled to a rotary dump at Elk Run shaft, dumped down a well and loaded again on the lower level for direct haulage to the coke ovens. This lower level is a part of the Rosedale Mines and dispatching is handled independently from the Rosedale end.

From this short article it will be seen that despite the size of the mine in question, the problem of dispatching is an easy one to handle, given a capable dispatcher who knows his mine and is on the job.

Should Starting of Electrical Machinery Be Regulated by Automatic Devices?

By H. H. Johnston*
East Pittsburgh, Pa.

IN THE article entitled "Year 1922 Tackles Hopefully Many of the Big Problems of Coal Production and Preparation" that appeared in *Coal Age* Jan. 18, pp. 89-91, the author says:

> One wonders whether the time will not come when the man who runs a locomotive or even a medium-sized hoist will be afforded opportunity merely to start the sequence of actions by which full power is developed or shut off, instead of being able to throw the controller handle with utter disregard of all the rules of proper operation. This provision is already embodied in electric railroad work. Why should the motorman have it in his power to "goose" a motor? If we had electricians to handle electric machinery the present equipment might be properly used, but with machines started by motormen, machine men, ditch diggers, pumpers and hoistmen little latitude of choice should be allowed. It is to be hoped that within the space available on the locomotive, mining machine and loader some means will ultimately be found to put devices which will prevent the motorman, cutter and loader, respectively, from abusing their motors.

These remarks were forwarded me by the author in a letter under date of Jan. 6, asking for my opinion relative to their practicability. They express without a doubt a thought to which operators, manufacturers and engineers have given much consideration. The conditions under which mines are operated vary so much, particularly in main and gathering haulage, that automatic control of the character in use on railroads is, I believe, entirely out of the question.

The locomotive of the mine is called upon to operate under conditions which vary widely with different kinds of operatives, trip lengths, track conditions, grades, etc. On the other hand it must always be remembered that in street-car service, owing to a fear that too great an acceleration of the car would cause discomfort to passengers, the maximum speed of acceleration usually is limited. Furthermore, the cars in street, elevated or subway railway service which use automatic control actually carry the burdens which they transport instead of trailing those burdens behind them in a trip of cars. This weight bears down heavily on the wheels so that the acceleration sought rarely is enough to cause the wheels to slip on the rail. On the other hand, the mine locomotive in the course of every run may be required to start at the slipping point of the wheels, as, for instance, when starting the train on an upgrade. It also may be called upon to start with an inordinately light load, where the tractive effort would be much below normal.

In railway equipments the usual practice is to use a current limit relay which during the acceleration periods automatically controls the various switches or contactors. This relay lifts when the accelerating current has reached a predetermined value. Under these conditions, should the motorman attempt to notch the controller quickly to the last step, the limit relay will lift as he passes a certain point and the accelerating switches will not be brought into action till the limit relay will drop, and this will be when the accelerating current decreases as the result of increased car speed.

Where remote-control devices are used—that is, where a master controller is operated by the motorman and

*General engineering department, Westinghouse Electric & Manufacturing Co.

contactors are controlled from the master controller—it is comparatively easy to provide for the automatic control of the motor and to do it without additional equipment. But when we come to the mine locomotive, it is, I believe, necessary to remember that we must have notch-by-notch control even if we do have the automatic feature. There are many times when mine locomotives must be operated for a long time on the resistor points. Any automatic features used to take care of the needs outlined in the article quoted, therefore, must be used in conjunction with the ordinary step-by-step control.

If automatic acceleration were provided in the same manner as on street railway cars either the current limit relay should be changed in every case so that it would be adapted for the acceleration of the locomotive and its trip under the particular load condition encountered or the automatic devices for the control of acceleration should be more adequate than could be provided by the use merely of a current limit relay. In conjunction with that device should be one dependent on the time element so that under all conditions provision would be made for bringing in the accelerating switches, one after another, with a definite time interval between them. Automatic acceleration by the current relay is not used in main-line electric, freight, passenger or switching locomotives for precisely the same reasons that operate against its use in mine-locomotive service.

Where Regulation Has Been Made Automatic

Perhaps the only instance around coal works where locomotives have been controlled by automatic devices has been on some of the more recent quencher locomotives used at byproduct coke plants. But these are operated under a loading and grade condition that is always practically the same, day in and day out and trip after trip. In these installations a master controller is used, having the usual notch-by-notch scheme of control, but having in conjunction with this a provision for automatic acceleration in case the man who handles the locomotive wilfully or otherwise turns the handle of the controller too fast to the last or intermediate running points. On these locomotives electro-pneumatic unit switch control is used. With it is embodied a current limit relay and, as stated, manual control.

Various mechanical devices have been designed for use with mine-locomotive controllers. Drum controllers also have been put into street-car service. These make it necessary for the motorman to consume time in operating his control handle from notch to notch. Motormen become expert in handling most of the devices of this kind which have been put on the market, and even though they are supposed to delay the motorman materially in passing from notch to notch they do not always prevent him from abusing the equipment entrusted to his care.

Undoubtedly the question the writer has in mind is: Will the control operation become eventually so simplified that the sequence of actions will be started by the pressing of a push button. It is difficult to see how this will come about, especially in mine-locomotive service, but it is not at all impossible to foresee that we may yet use a master controller, a set of contactors, and a reverser in conjunction possibly with a current limit relay so as to provide sequence of the control circuits, provision being made on the master controller and between the various contactors for the operative to obtain notch-by-notch acceleration either to resistor or running points.

Under existing conditions at many mines the motormen and operators of other electrical equipment cannot be penalized sufficiently for the damage they do when they operate their controllers in the manner described in the article. For reasons not electrical, such actions under certain conditions could not be penalized, but perhaps there are other ways of preventing the abuse of equipment.

I have in mind a sort of recording device that might be planned and applied to the various mine equipments which would tell the operative or would record for the mine superintendent or other official, either directly or indirectly, what savings the motormen and other operatives in the mine have made possible by more careful and capable operation of their controllers.

No doubt if such a device were installed, even though it would show nothing more than the saving in power, a considerable reduction would be made in operating expenses. This would reveal, however, only a part of the saving that would arise from the careful operation of the controller which such a record would cause. There would be a further saving not noted on the record, for the installation of the device would greatly reduce the number of equipments that fail today by reason of power being too rapidly applied to the motors.

British Columbia Seeking Uses for Fossil Resins of Coalmont Mines

IN AN article read before the Canadian Institute of Mining and Metallurgy, R. T. Elworthy and R. K. Carnochan discussed the possibilities of using a fossil resin found in the coal on the waste dumps of the Coalmont Collieries, Coalmont, B. C. This material aroused much interest, especially as it is reported to be identical with Prussian amber. Of 400 lb. of the coal sent to the Mines Branch of the Department of Mines of Canada, resin formed about 8 lb. The pieces were about the size of a pea, were irregular in shape, without marked cleavage lines and fairly brittle. Their color varied from opalescent lemon yellow through all stages from brown to black, some showing a green fluorescence. It readily can be separated from the coal by flotation in solutions of sodium or calcium chlorides of specific gravity 1.10 and graded by using solutions of specific gravity 1.03, 1.05 and 1.09. Ultimate analyses gave a composition of about 80 per cent carbon, 10 per cent hydrogen, 9 per cent oxygen, 0.3 per cent sulphur and 0.7 per cent ash.

The amber made an excellent varnish that did not crack but was of rather a dark color. The manufacturers of varnish feared that it would not compete with copals such as the Zanzibar, Kauro, Manila and Congo gums.

Large-sized blocks of amber are formed from clippings and waste by the action of heat and pressure. According to one process the material is heated to 200-250 deg. C. and a pressure of 400 atmospheres applied. Experiments made in the compression of Coalmont resin have not yet been successful, though it is hoped that better results will be obtained with a new mold now being made in the work shops.

But the synthetic resins such as Bakelite, Redmanol and Condensite are rapidly supplanting compressed amber and it is improbable that there is any use for the Coalmont resin in this direction. It therefore seems difficult to find satisfactory uses for the resin unless it can be obtained in large quantity and sold cheaply enough to compete with the darker varnish stains.

Extracting Thick and Steeply Pitching Coal Seams

Galleries Are Extended Either from Shaft or Chuteway, the Coal Thus Entered Being Extracted by Shots in Sides and Roof of Roadway—In Other Sections Diagonal or Vertical Breasts Are Driven and Drawn Without Stowing

By A. Gerke
Waldenburg, Silesia, Germany

NO UNUSUAL difficulties are experienced in the working of thin seams, even when they pitch heavily, but the mining engineer often must face difficult problems if the pitching seam is from 20 to 25 ft. thick, for in such cases methods that are quite efficient with thin seams cannot even be considered. In most instances, where the beds are thick, either cross working or stoping methods have been adopted. Even until recent years one German coal mine has been operating on this latter principle, the excavation being stowed. The seam is from 20 to 25 ft. thick and pitches at an angle of 70 to 90 deg.

Expensive Stowing Methods Abandoned

The results obtained by this method were not at all satisfactory. Though the work was done with the greatest possible care the face of the coal frequently broke down owing to the friability of the coal and the thickness of the coal bed. In consequence the workings had to be substantially timbered. In some places the coal fell for a height of from 60 to 100 ft., and the stopes had to be abandoned and the roadways and airways had to be sealed. This had to be done with exemplary care, for if it were not so done or if when thus performed the seals became leaky, mine fires soon broke out, and hence it happened that in many cases, owing to the danger that the fire would spread, even unmined parts of the seams had to be abandoned.

Furthermore, the cost was too high and the returns were too small, and that was true even when no such accidents occurred. Consequently other methods had to be devised. On account of the unfavorable nature of the seam it could not be mined by working from footwall to hanging wall, stowing refuse in place of the extracted coal. This method, therefore, gave way to the stoping method just mentioned, and that in turn was abandoned for the method described in this article. The two systems used are termed "stockwork" (*etagenbruckbau*) and "working by diagonal stopes" (*diagonalbruckbau*).

The stockworks themselves are of two kinds, according to the character of the rock bed overlying the coal.

The coal area to be mined by stockwork is divided by hoisting shafts spaced at 350-ft. intervals. The small areas thus served are divided again into smaller areas by driving galleries 6 or 7 ft. wide in the middle of the coal bed—that is, at equal distances from the footwall and hanging wall. When these are driven to the full distance of 350 ft. the coal is extracted on the retreat on both sides of the gallery and up to the roadway above. (See Fig. 1.) First of all a raise is made to the gallery above. Then the roadway is widened to the full width of the seam for a length measured along the gallery of 14 to 18 ft. and the coal in the roof is shot down till the upper gallery is reached. Coal pillars are left about 10 ft. wide to separate the broken coal from the "old man," or fallen roof of the excavated area. By leaving pillars of this kind the coal is supported so as to form an arch which can be broken down only by well-located shots in the sides or the roof of the raise.

Arrange to Make Coal Pile Act as Chute

The cars are brought to the edge of the raise, for the coal comes down in such a large quantity that the loaders can work under the protection of the well-timbered roadway. In case sufficient coal does not fall

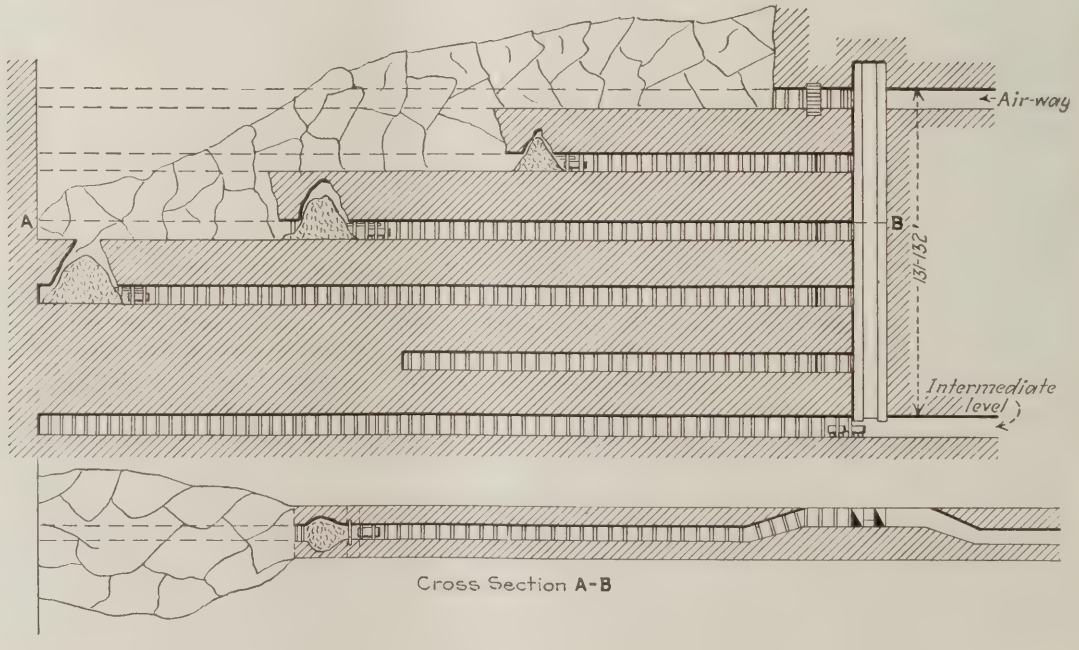

FIG. 1

Stockwork

In steep pitches over 50 to 70 deg. an inclined shaft is constructed directly on the pitch and galleries are driven along the middle of the seam for 350 ft. The coal above and beside the gallery is drawn out by cutting a raise in the roof, by widening the gallery and then shooting down the sides of the raise, the men working in the third operation on the top and sides of the coal pile.

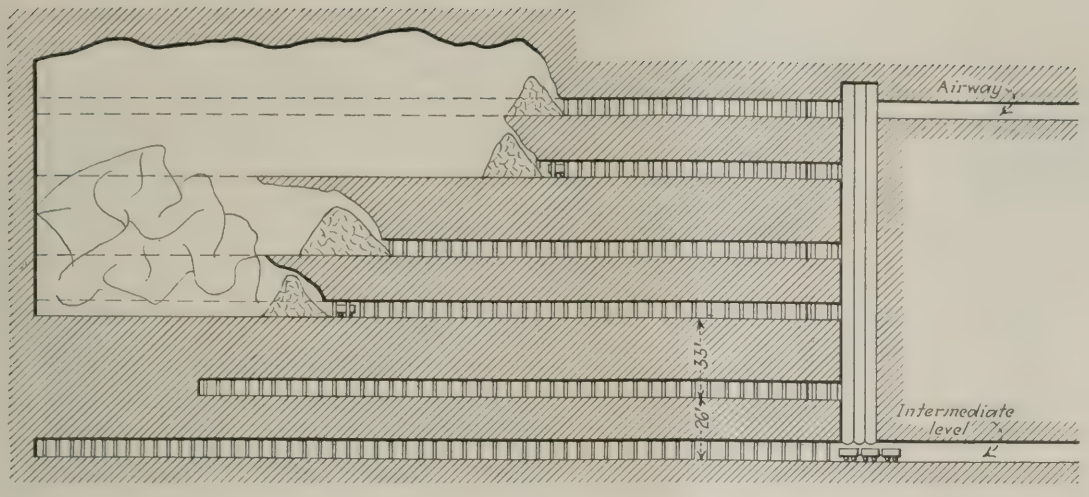

FIG. 2

Another Form of Stockwork

Here the roof is firmer and the seam thinner, 12 to 14 ft. thick. Two adjacent galleries in the retreat are brought back almost abreast and no vertical pillars are left against the goaf.

into the roadway the miners blast the next holes so as to bring down the quantity of coal required. For their own advantage they will not allow all the coal to be removed, for by means of the pile of coal they are able to drill other blast holes more easily. The coal thus piled on the roadway can be removed when the lower roadway has retreated an equal distance.

The cavity created by the extraction of the coal is filled with rock which falls from the hanging wall and the coal which has been left to protect the raise. The roof does not fall in large quantities but gradually.

If the hanging wall is solid and the seam runs only from 10 to 14 ft. in thickness the type of working illustrated by Fig. 2 is preferred. Here two galleries are worked at the same time and by one crew of men. No pillars are left to protect the raise except as a roof to every second roadway.

As the driving of shafts delays operations, and is expensive, entailing much deadwork, diagonal passageways rising at 45 deg. are now used in their place. These are driven as a rule without timber, and in them is placed an open wood trough. (See Fig. 3.) These chuteways are driven and maintained at less cost than inclined shafts, and the coal thus lowered to the roadway is broken less than if dropped down the full pitch of the seam.

Unless the inclination of the bed exceeds 50 to 70 deg. the stockwork method cannot be used to advantage, for the coal will not slide down to the point in the roadway where the cars are to be loaded. For this reason where the coal is of that lesser inclination the operation is by diagonal breasts, as shown in Fig. 4. This method has advantages over stockwork, for less development is needed, no coal is lost, the miners can produce more coal and less timber is used. Furthermore, a large percentage of the coal produced by this method is in large lumps.

The area to be mined is opened up by breasts inclined at 45 deg., the coal being withdrawn from the lower level. After the second mining is completed no pillars are left. The miners drill their blast holes standing on the coal already blown down. It was found that when working by stockwork or by diagonal stopes the miners produced 13 tons, where before, working in the stowed stopes, they mined only 4 tons. The costs of timbering were reduced one-eleventh and the wage cost of haulage one-third.

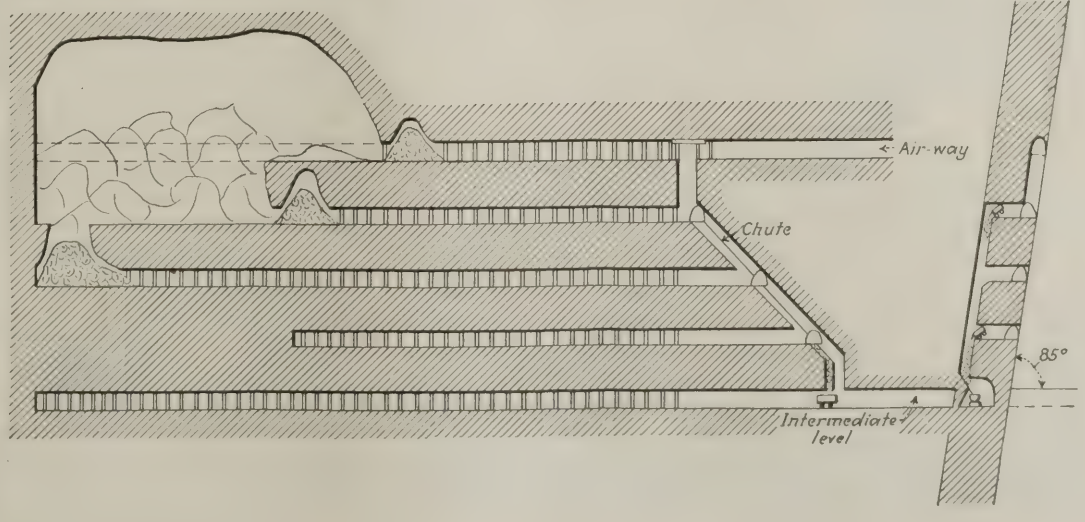
A modification of stoping in which the area is first divided into longitudinal pillars has recently been used in a seam dipping at 30 to 50 deg. (Fig. 5.) The area to be extracted is divided into sections by subordinate passageways from 90 to 145 ft. apart driven up the pitch. Passageways or galleries are driven on the line of strike at right angles to these and at intervals of 33 ft. Mining may be started at the top gallery or at the lowest one.

The longitudinal pillars are split by a narrow breast up to the gallery above. Then concurrently the pillar toward the goaf is drawn and a slice is taken off the pillar on the other side so that in all the seam is removed for a width of about 20 ft. This may be taken working upward or downward. In either case a 10-ft. pillar of coal is left at the top of the gallery to protect the work in the section below. Eventually this coal will

FIG. 3

Stockwork with Diagonal Chuteway

Here the grade is almost vertical and the coal accordingly is run down a wood trough through a chuteway driven at an angle to the full pitch—in this case of 45 deg. — thus reducing breakage. This method is known as *"etagenbruckbau mit diagonalen rolloechern."*



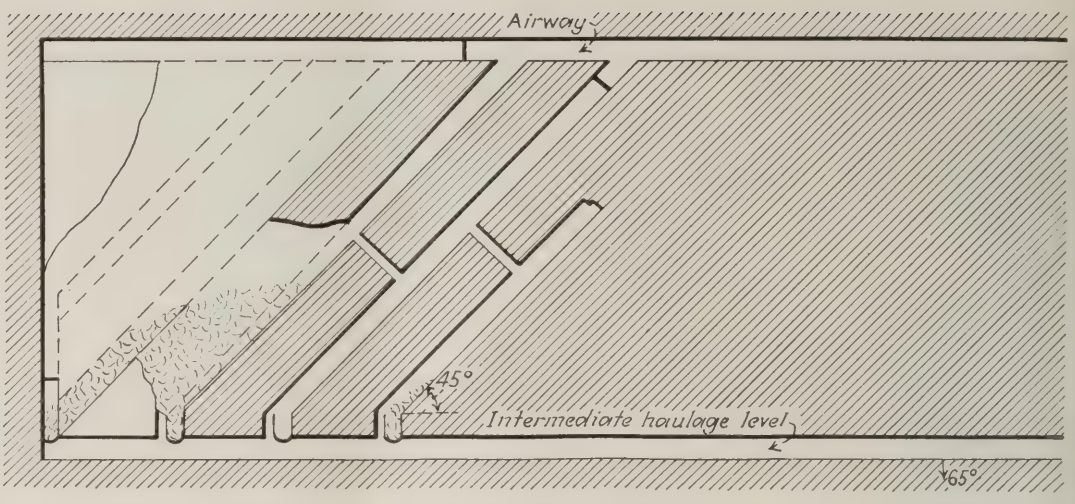


FIG. 4

Diagonal Breasts

Where the pitch does not exceed 50 to 70 deg. stockwork cannot be used. Here diagonal breasts are introduced, which have the advantage of saving in development cost, larger tonnage per man, less coal lost, less timbering required and lumpier coal. The method is termed *diagonalbruckbau*. The rooms are drawn starting from the lower gallery.

be broken down and loaded, as also any coal left between the breast and the goaf. This is worked downward.

The coal excavated in any such breast is dropped down to the gallery below and loaded into mine cars. A line of props is set along the coal pillar at the top to prevent it from breaking down. While working the miners stand on solid coal and they can put their ladders on it in a right angle to the inclination of the coal bed. They are well protected, for the coal they are cutting cannot touch the ladders.

After blasting the men can get back to the working face from the upper gallery, which with proper care can be protected from the falling of coal. As for the trammers, they are well protected, being in the lower gallery. The advantage of this method is that it reduces the waste of coal and affords greater protection to the men.

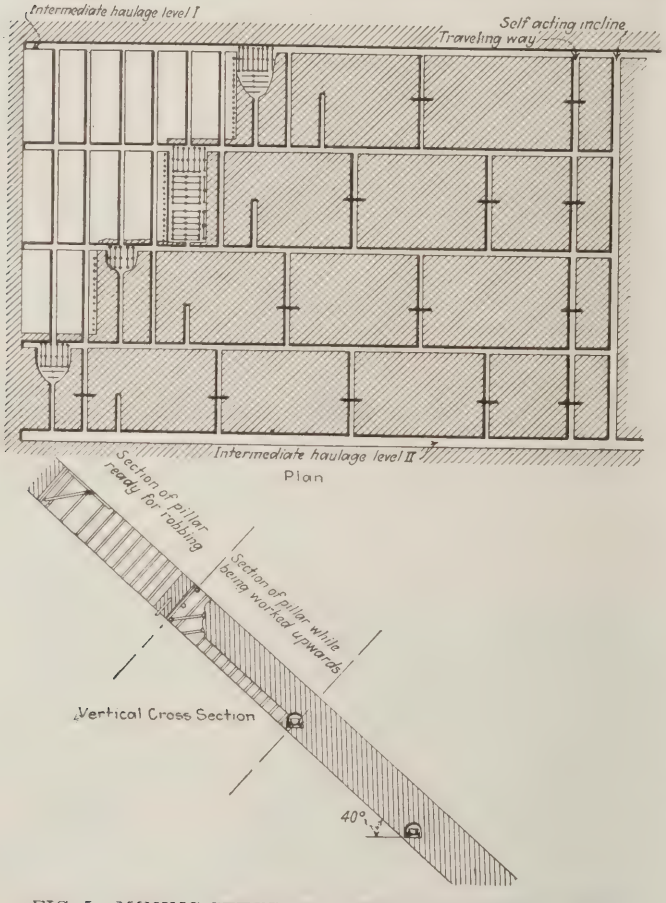

FIG. 5—MINING STEEPLY PITCHING BEDS IN PANELS

Working by longitudinal pillars with inclining sections (*streichender pfeilerbau mit ein fallenden abschnitten*). The work is divided into large panels which are split by small narrow breasts, most or all of the coal being taken out on a retreat, upward or downward. Pillars are left at the top of the galleries to prevent broken roof rock from falling into the breast.

The methods of working just described have proved their value by long use. Of course, they can be employed only if the surface does not need to be supported and when the dip as well as the width of the seam accords with the conditions outlined. These requirements being complied with, the methods can be recommended.

Code for Trade Associations Laid Down

IN place of criminal or even civil proceedings under the anti-trust laws against the Gypsum Industries Association, a decree by consent has been entered in the New York Federal District Court dissolving the association and stating what its members may and may not do in concert in the future. This action followed a widespread investigation by the government and the presentation of evidence to the federal grand jury, which according to report was reluctant to indict but indicated a desire that the government should secure the cessation of alleged abuses growing out of the association's activities. This course of action, far more just and practical than inconclusive prosecution such as has been brought in other industries, was adopted.

The decree agreed to by the United States Attorney and the representatives of the gypsum manufacturers prohibits the weekly or monthly meetings which the government contended afforded opportunities for price fixing, dissolves the association and in its place substitutes a non-profit making corporation. The acts of this corporation which are held to be lawful and to which the corporation is limited by its charter, include advancing or promoting the use of gypsum products by all legitimate means, including research, publicity and advertisement, dealing with engineering and trade problems pertinent to the industry, carrying on educational work, maintaining a bureau to furnish information, dealing with improved methods of plant and mine operation and maintaining a credit bureau.

The injunction provisions of the decree prohibit agreements to

Fix or establish prices for gypsum products.

Establish or maintain uniform prices.

Advance or decrease prices.

Limit, curtail or otherwise control the production of gypsum products.

Fix boundaries of sales territories open only to certain members.

Effect any discrimination in prices.—***The Index.***

Problems of Operating Men

Edited by James T. Beard

Work for Fact-Finding Commission Appointed by President

Cost of Production and Distribution of Coal—Law of Supply and Demand Automatic—Little Need for Intermediaries

ONE of the important duties devolving on the Fact-Finding Commission to which reference has been made in *Coal Age*, Dec. 14, p. 959, will be the determination of the cost of production and distribution of the coal, from its mining till it has reached the final consumer. The work of the commission is to collect data to show the sources responsible for the high prices now being paid for fuel.

In various ways, attempts have been made to explain the present excessive price of coal to the ultimate consumer. Most pronounced of the reasons given has been the high rate of wages paid to miners and mine laborers. This theory, however, would place the responsibility where a more thorough investigation may show that it least belongs

Miners' High Wages Not Alone Responsible for Excessive Cost of Production

The high wages paid to miners and mine workers form a comparatively small item in the actual cost of production and distribution of coal to the consumer. From the time the coal leaves the mine, until it reaches its final resting place in the bins of the consumers, there is every evidence of excessive charges for transportation, handling and distribution by trucks and drays.

For a number of years, there has been a too pronounced differential between the cost of mining the coal and the price paid by the consumer. This differential is too great to be explained by the operation of the natural law of supply and demand. It is well known that this law acts naturally and automatically only when it is unrestricted.

Interference with this natural law has been emphasized by the government as criminal, in the pronouncing as a crime any manipulation in restraint of trade. With equal fairness and justice, our laws might also define as crimes, transactions that divert or obstruct the flow of commodities from the producer to the consumer by the simplest and most direct route possible.

Two Classes of Consumers

In general, there are two classes of consumers: 1. The manufacturer and others who purchase coal in carload lots. 2. The individual or small consumer whose requirements demand less than carload shipments. It is evident that the differential in the former instance is much less than that in the latter, which must involve the service of a retail intermediary as a distributor of coal in retail lots.

The consumer who buys in carload lots must pay a price that includes the cost, f.o.b. at the mine, together with freight charges and expense of handling at destination. On the other hand, the small consumer pays in addition, the cost of handling the coal twice and the profits of the retail dealer.

Handling of Shipments of Coal Through Brokers Harmful to the Industry

There is a class of operators that should be styled "industrial parasites," whose operations are as much against the interests of the producer as against those of the consumer. There is no legitimate excuse or logical reason for the existence of these parasites, in any capacity, in the coal industry. Their operations are confined solely to brokerage in the handling of the product.

There are brokerage firms that do an annual business amounting to millions, on a comparatively small invested capital. Their purchases are sold in the open market or to their clients, at the prevailing market prices, but that is no argument in their favor.

In the handling of large volumes of commodities, such as fuel, it is of the utmost importance that the transportation of the product should be by the most direct route and in a manner to avoid unnecessary transfer charges and demurrage for delay in unloading. All such unnecessary charges increase the cost to the consumer.

In closing, I will mention briefly the opening of small mining operations at the time of the war when the great demand for coal sent the price skyward. These small mines were known as "Snowbirds." They helped in the emergency, although practically their entire output was handled by brokers.

In closing, let me express the hope that the Coal Commission will be able, through its statistical data, to establish the existence of many of the evils that now prey on the coal industry.

Washington, D. C. I. C. Parfitt.

Economy and Supervision Needful

Economy in the use of rails, ties, brattice cloth, etc., important in the operation of a mine—Custom in England—Practice in Rock Springs—Careful supervision needful.

IN HIS interesting letter entitled "Economy in Use of Mine Timber," *Coal Age*, Nov. 16, p. 800, Richard Bowen expresses surprise that, in suggesting ways of improving mining, I failed to mention the practice of economy in the use of mine timber.

Permit me to say, here, that this was not an oversight on my part, as I am a great believer in mine economy, as viewed from many angles. My previous letter did not include economizing in timber, because of lack of sufficient space. However, timber is not the only item requiring the practice of economy. There are rails, ties, brattice cloth and boards, pipes and fittings, together with numerous other supplies.

Just here, I am reminded of a custom in England that might well be followed in American mines. There, when the coal pillar is being drawn back to the entry stump, the deputy, or fireboss, and the miners working the place remain after quitting time and pull out the track and such timber as can be drawn with safety. Nothing is left to be covered up and lost.

If my information is correct, practice in the Rock Springs district, here, allows every miner who has finished his place a bonus of 10c. for each prop he can take out. To my mind, this is a bad arrangement, as only the most experienced men should be permitted to draw timbers from a place about to be abandoned. The work is a dangerous undertaking.

Ascertaining Conditions Underground

A short time ago my attention was arrested by a statement, in *Coal Age*, that some large coal companies were employing private detectives to go through their mines and observe and report on the manner in which they were being operated. This struck me as a good stunt, which might well be adopted in many other mines, where the entire supervision of the underground work is left to one busy foreman, who can hardly keep pace with all that is going on in the mine.

As has been stated by other writers, in *Coal Age*, there is hardly a question but that many wasteful means and methods are being employed in the extraction of coal. I have asked myself the question, Why should not our government take steps to correct this evil? In the conservation of national resources, why permit the operation of mines on a poor basis?

One example showing the need of some more effective supervision of coal operations is the recent explosion at Whitehaven, England, by which, I believe, fourteen miners lost their lives. The explosion occurred half an hour after the men had entered the mine for work, which might suggest that the fireboss had not been able to make a thorough inspection of the workings as required by law.

According to my information the fireboss who examined the mine was compelled to work twelve-hour shifts, which was contrary to the Mine Regulations Act, and his report stated that the district was "clear of gas."

About two years ago I visited in the Whitehaven district going into the Lowca mine where all the miners were using flame safety lamps. Glancing over the deputy's reports for three months back, I was surprised not to find a single gas report; but according to the talk of the miners there was plenty of gas in their places. The fact seemed to indicate that the deputy never made a true report of the mine.

Frontier, Wyo. William Allan.

Developing Ability in Men

Getting things done a peculiar quality of bosses—As the average man sees himself—The man in a rut—Mistakes of companies in training their men.

A SHORT time ago an article appeared in *Coal Age* (Jan. 4, p. 17) bearing on the relative effects of diplomacy and merit in the training of men to be capable workers. In line with what was said by that writer, I am constrained to suggest another viewpoint in the training of men.

Getting things done is a peculiar quality that very few bosses possess. The big problem for the man who employs men is to impress on the fellow who is not hitting on all six cylinders that there is room for improvement. To bring him to understand that fact and accept, in his own mind, the possibility that he can do better is often a difficult matter.

As a general proposition, a man wants to be the judge of the quality of his own efforts. The average man, as he sees himself, thinks and feels that he is doing well. In the majority of cases, he solaces himself with the thought that he is accomplishing more than for what he is paid.

Often have I noticed that when a boss was doing badly, in comparison with other employees of the company, the matter of any improvement in his methods has to be approached with tact. In nine cases out of ten, the man will be possessed with the notion that he is doing well.

At times, it has happened the man would realize that the results he had accomplished were far from satisfactory. But, in such cases, he would claim that the proposition was a hard one, and give it as his honest opinion that he should be paid more money for sticking to the job.

Unwise Handling of the Man in a Rut

We are all familiar with the man who is in a rut. It is hard to convince him that another method than the one he employs would bring better results. If such a one can be brought to open his heart, however, it will often reveal the secret that, had he the opportunity, he could show the boss a few things that would open his eyes.

Some companies handle a situation such as this by dismissing a foreman who has failed by reason of his overestimating his own qualities. This is a great mistake and the concern that assumes such an attitude will never develop capable officials. Instead, they will find themselves continually going outside of their organizations in search of good men. Such a course is too much of a gambler's chance to be recommended.

In closing, let me say that every large coal company should seek to train its men to a more correct estimation of their own qualities. It may take time but in the end will prove worth while. George Edwards.

Pikeville, Ky.

Teach the Rudiments of Mining in Our Public Schools

Coal mining an honorable occupation—Its importance enhanced when taught in schools.

WITH some little surprise, I read the letter of John Rose, *Coal Age*, Dec. 14, p. 961, commenting on my previous suggestion regarding the teaching of the rudiments of mining in our public schools. Mr. Rose says that this "would be difficult, expensive and in a large measure unprofitable." It would seem that our friend's chief objection comes from the fear that the teachers in our public schools have not sufficient knowledge of mining and the attempt would only prove a failure. It may be true that many of the teachers' knowledge of practical mining is quite limited. At the same time, are they not equally ignorant of the rudiments of agriculture, which is being urged and is now taught in many of the schools?

In making this suggestion, my idea was that the teaching of the rudiments of coal mining would impress the child that it is an equally honorable occupation as

that of farming. Moreover, it would give to the children of coal miners an equal start in the work that falls to their lot, as enjoyed by the children of farmers who will be employed in tilling the ground or in other pursuits.

Unfortunately, the work of mining coal has come to be regarded, in the opinion of many, as a degraded occupation. If this idea is to be eliminated from the minds of our younger generation, it will be necessary to adopt some method that will impress them differently, by showing that the work requires both skill and intelligence, to an equal extent with the occupation of a carpenter, machinist or store clerk.

As far as the cost is concerned, the publications on elementary mining, issued by the various vocational boards, are available as textbooks, and arrangements could be made with most coal companies by which their engineers could assist in giving the needed instructions, say once or twice a week.

Advanced Course to Be Taught in High Schools

In the high schools, a more advanced course of study could be offered by the employment of a competent instructor, similar to those now employed to teach manual training, agriculture, etc. In this district, there is employed, in the high school, an instructor to teach agriculture, at a salary of $2,200. Although essentially a coal mining district, there is no similar provision made to teach coal mining.

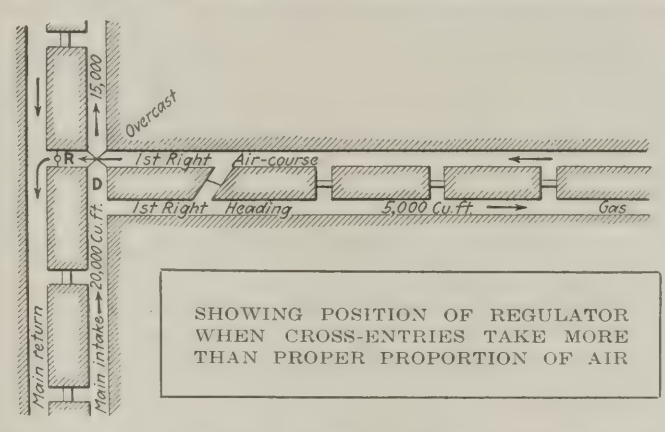
That the coal industry is one of the most vital of occupations, no one will deny. In fairness and justice to those who follow this pursuit, the same advantages should be open to this as to other classes of workers. Money spent for that purpose would be a profitable investment, if it resulted in bringing a higher proportion of English speaking employees into the mines. The natural results would be that the average father, himself a coal miner, would have no hesitancy in encouraging his children to follow the occupation that has been his life work.

Thomas Allen.

Mount Harris, Colo.

Inquiries Of General Interest

Position of Mine Regulator and Effect of Air Leaks



Regulator Required When Door Is Taken Out and Overcast Built—Where Should Regulator Be Placed—Effect of Leaky Door or Stopping

KINDLY permit me to present the accompanying sketch, showing the first-right pair of entries turned off the main heading in our mine, and to explain the following condition that has given rise to much discussion here, in reference to some points.

As shown in my sketch, there is 20,000 cu.ft. of air passing on the main heading. Until a short time previous, there had been a door at the point marked *D*, at the mouth of this pair of cross-entries. The door has now been taken out and an overcast built for the purpose of furnishing a separate split of air to ventilate these entries, which require about 5,000 cu.ft. per min.

We discovered right away, however, that it was necessary to use a regulator, in order to obtain the desired division of the air. Without the regulator, it was not possible to control the air in the proportions desired. The question arose at once as to where this regulator should be placed and this is the first question I want to ask.

Again, it is claimed by some that if the door on the crosscut near the mouth of the cross-entries should leak air, or if any of the stoppings on this pair of entries did

SHOWING POSITION OF REGULATOR WHEN CROSS-ENTRIES TAKE MORE THAN PROPER PROPORTION OF AIR

the same, it is possible for some of the return air to be drawn through this leak back into the intake, or fresh-air current. If that is possible, please explain under what conditions it might take place.

Again, I wish to ask, How would this leak affect the remainder of the current passing through the regulator?

These questions have been under discussion, without reaching any definite conclusion, among a number of mining students attending the State College Extension Course, in Barnesboro. I believe the question first came up at the mining course of the State College some time last summer, and we are all anxious to reach a satisfactory conclusion.

James Bacon.

Barnesboro, Pa.

In answer to the first question regarding the proper place to put the regulator, there is not sufficient data given to answer this question directly. The correspondent should have stated how much the mine is developed beyond this first pair of cross-entries on the right, as compared with the development of the entries themselves.

For example, after building the overcast and taking down the door on the main heading, the location of the regulator will depend on whether the cross-entries take more or less than the desired amount of air. This, of course, is determined by the relative resistances of these entries and the balance of the mine. If the cross-entries are taking more than the desired 5,000 cu.ft. per min., the regulator must be placed on that split.

On the other hand, if the cross-entries are receiving less than the desired proportion of air, owing to their resistance being greater than the remainder of the mine, the regulator must be placed at some point on the main current, so as to force more air into the cross-entries.

In placing a regulator of the box type, consisting of a brattice having an opening provided with a sliding shutter, such a regulator must be placed on the back entry where it will not interfere with the hauling of coal. If the regulator is placed on the air split traveling the cross-entries, it can be located at the point marked *R*, in the accompanying figure, or similarly on either side of the overcast where it will be out of the way.

Referring to the second question, the pressure on the intake of a pair of entries is always greater than that on the return and air can never be drawn from the latter into the former, under any normal working conditions.

The reply to the third question is that a leaky door or stopping on the air split, by short-circuiting some of the air, will cause a surplus of air to pass through the regulator and require a larger opening therein, if the desired 5,000 cu.ft. per minute is to be maintained at the face of the entries. This condition, however, will require increasing the power on the air.

Examination Questions Answered

Mine Formen's Examination Lexington, Ky., 1922

(Selected Questions)

QUESTION—*(a) In your opinion, is black powder dangerous in solid shooting? (b) Is permissible powder safer than black powder in solid shooting? (c) Under what condition should solid shooting be allowed?*

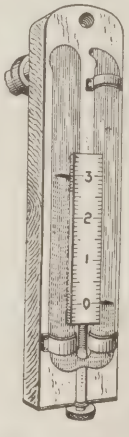
ANSWER—(a) Black powder is particularly dangerous in shooting coal off the solid, because of the liability of the occurrence of a blownout or windy shot, by reason of the coal not having been properly mined or sidecut. The large volume of flame produced by the explosion of black powder affords every opportunity for the production of a dust explosion.

(b) Permissible powder is always safer than black powder, because it is practically flameless when the shot is fired, and there is not the same liability for the production of a dust explosion.

(c) Solid shooting cannot be said to be safe in the mining of bituminous coal, although if the shot is well laid by an experienced miner, no bad results may follow the firing of the shot. The practice of solid shooting prevails largely in the mining of anthracite and the harder varieties of bituminous coal.

QUESTION—*What precautions would you take in entering old workings that have been sealed off?*

ANSWER—Ample time should be given, after breaking down the seals and allowing fresh air to enter the place, for the current to dilute and sweep away the dangerous gases that have accumulated. The place should be entered at the intake end. No open light should be used, but only an electric cap lamp or an approved form of safety lamp should be carried. The advance must be slow and frequent tests made to determine the condition of the air by observing its effect on caged mice or birds taken along for that purpose, or the Burrell gas detector must be employed. No one should attempt to enter such a place alone.



QUESTION—*In case a workman is in contact with a live electric wire, how would you release him? If the man is rendered unconscious, how would you proceed to revive him?*

ANSWER—No time must be lost. Shut off the current if a switch is at hand. Otherwise, throw an iron bar or drill across the wire, on the side of the victim toward the powerhouse, for the purpose of short circuiting a portion of the current and lessening the amount passing through the body. A better plan, however, is to cut the wire on the power side, by a single blow of a sharp ax, when that can be quickly done. Care must be taken to stand on dry ground. It may be possible to quickly drag or push the victim from the wire, using a dry pole for the purpose; or by catching a hold of the man's dry garments and standing on dry ground while so doing.

If the victim is unconscious, he should be moved quickly to where he can have better air and artificial respiration applied in the usual manner. Laying the man prone on the ground with his face turned to one side to admit of free breathing, and the tongue moved forward in the mouth, the operator kneeling astraddle of the man's sides, spreads his two hands over his loins or small of his back and alternately brings a strong pressure on the body to expel the air from the lungs and again releases the pressure to permit air to enter This alternate compression and release must be repeated at the rate of about sixteen times a minute, corresponding to the rate of breathing. The operation must be continued until the patient is revived or life is pronounced extinct by a physician.

QUESTION—*What is a water gage and how is it read when applied to the action of the air current in mine airways?*

ANSWER—As shown in the accompanying figure, the water gage consists of a glass tube bent in the shape of the letter U, and mounted on a wooden base, one branch of the tube being extended at a right angle so as to pass through an opening in the partition dividing the intake and return airways. Both ends of the tube are open to the pressure of the air.

In use, when the water gage has been placed in position on a partition separating the intake from the return airway, the water in the bend of the tube is depressed by the greater intake pressure of the air and rises an equal amount in the other branch of the tube. The difference in the water levels in the two branches of the tube is measured by the scale, the zero of which is adjusted to the lower level and the reading of the upper level is then the inches of water column, or the water gage measuring the difference of pressure between the two airways.

Each inch of water gage corresponds to a pressure of 5.2 lb. per sq.ft. circulating the air from this point on the intake to the same point on the return. In the figure, the water-gage reading is 3 in., indicating a ventilating pressure of $3 \times 5.2 = 15.6$ lb. per square foot.

QUESTION—*What are timbers used for in mines?*

ANSWER—Timbering of roof, in mines, serves two purposes. First, standing a timber under a loose piece of rock may prevent its fall, until such time as the timber is withdrawn. Again, the condition of the timber serves to indicate the action of the roof and gives warning of any increase in roof pressure that may be dangerous. This is made known by the crushing of the timber or of the cap-piece between the roof and the top of the post. In a few words, timbers are used, in mines, for the purpose of giving the miner warning of any unsafe condition of the roof above him. Mine timbers are not used with the idea of supporting the entire overburden.

Coal Situation Discussed from All Angles By New York Section of A. I. M. E.

Stating that coal in the Government Fuel Yard at Washington cost 16c. less in January, 1923, than in the corresponding month of the year previous, H. Foster Bain, director of the U. S. Bureau of Mines, at the meeting of the American Institute of Mining and Metallurgical Engineers at the Chemists' Club, New York, Feb. 14, explained that this was due to the fact that the coal was purchased only from the large companies that had only slightly adjusted their prices. The freight had been reduced 36c. per ton and the price of coal at the mine had been raised 20c., thus accounting for the reduction in the cost of the government.

He stated that the government handled the coal for $1 per ton but he did not desire it to be thought that the average retailer under the conditions he must face could attempt to handle coal for less than $1.88 per ton. Later in the evening Roderick Stephens, vice-president of the Stephens Coal Co., of New York City, took issue with Dr. Bain, saying that from inquiries he had made in Washington, acting for the retailers, he had been brought to the conclusion that the real cost of handling coal at the Government Fuel Yard was about $1.76 per ton. Dr. Bain admitted that the government business was of an exceptional character and the figures it obtained in conducting its business could not be generally applied. Dr. Bain was not prepared to offer any proposals for the correcting of the alleged evils in the coal situation but he listed those which were being presented: Nationalization, unlimited railroad-car supply, unrestricted competition, larger corporations, general unionization, deprival of the right to open mines except under proof of public convenience and necessity and a grant to the Secretary of the Interior of the right to refuse to lease public coal lands where the output from such lands was not needed to meet public needs.

Dr. Bain in his comments said that to demand that the railroads furnish cars and locomotives sufficient to match the present ability of the mines to produce coal would put an unreasonable burden on the railroads. He declared that he never had been able to understand why coal companies had not more generally combined and why the coal industry was wholly conducted by small companies. He believed that it might be possible to compel anyone who wanted to open a mine to show "public convenience and necessity" before allowing him to construct a railroad switch or before permitting the railroad to do it for him. When a new road is to be built the railroad is obliged to show proof that it will be advantageous to the public. He could not see why the arm of the government could not control the constructional activities of the mines as it has done those of the railroads.

Shows Inconsistency of Government Policy

Referring to our public land policy in the West, Dr. Bain said that the U. S. Government was preaching one doctrine and following an entirely different one. It was generally conceded by everyone in the government and without it that there were too many mines and too many miners. Yet the Department of the Interior was compelled to lease to anyone any coal land comprised in the public domain. Worse yet, it was obliged to require of any lesser that he mine a certain quantity of coal each year on pain of forfeiture. That was done because the government did not want to see public lands gobbled up by those who sought them solely that they might hold them for speculation. To avoid that it was necessary to require that the coal be mined. In view of the fact that the Western mines were already working short time for lack of market, to require the opening of mines seemed a suicidal policy. But what could be done under the law? A man recently approached the department to obtain a lease for 1,000 acres. That acreage contained at the least estimate 45,000,000 tons. It might contain 180,000,000 tons. The department was obliged to demand that the lessee mine 100,000 tons per year. At that rate the land would not be exhausted for 450 to 1,800 years. When asked why he wanted so much, the lessee replied that any less acreage would not impress Eastern bankers and would find them unwilling to advance the money needed. So a nation deploring the fact that capital and labor were being wasted by the excessive development of coal lands was itself demanding that more mines be opened and more men be employed. Could a greater contradiction between principles and practice be conceived?

Dr. Bain added that according to Hugh Archbald the miners when employed spent 3½ hr. working and 2½ hr. waiting for cars out of the 6 hr. that the men spent in their working places.

E. W. Parker, director of distribution of the Pennsylvania Fuel Commission, was the next speaker and the principal features of his address are summarized on page 348. Dr. Parker said that the companies in the anthracite region had expended $30,000,000 in pumping, ventilation and other expenses incurred during the strike. For this they did not have a single ton of coal production to show. They are not trying to get this money back and have not raised their prices except to balance increased taxation. Local taxes had increased inordinately and a state tax had recently been imposed. The anthracite companies realized that owing to the strike they would have only 60 per cent of the coal needed by the consumers during the present coal year. Accordingly the quantity provided to each section was 60 per cent of that accorded under the former U. S. Fuel Administration. Every effort had been made to keep quotas up to, and down to, that figure.

Samuel A. Taylor, consulting engineer and operator, of Pittsburgh, Pa., advocated a freight rate strictly based on mileage plus gathering and terminal charges and said that in the older mining sections the coal land in which small mines could be opened already was almost exhausted. He did not believe that it was just, advisable or constitutional to regulate the opening of new mines on the plea that such mines were neither a public convenience nor a necessity. Mines do not necessarily enter into interstate commerce and therefore are not, at least when opening, matters for federal control.

Roderick Stephens spoke briefly and was followed by R. C. Morse, Jr., superintendent of freight transportation of the Pennsylvania R.R. Mr. Morse declared that the shipment of coal to New England had been hampered by lack of facilities for water transport, and this had made difficulties for the railroads. Where the use of a car for twelve days was needed to transport a carload of coal to Tidewater, that use was extended to sixty or more days when the coal was transported to New England by railroad. The railroads, however, had not fallen down, but had done a larger business than ever. The Northwest demanded a return of its box cars during this period of stress but it had been unwilling to return the open-top equipment which it had borrowed from the East.

George Otis Smith, of the U. S. Coal Commission, spoke in the absence of John Hays Hammond, chairman of the commission. He said that undoubtedly the commission would endeavor to introduce remedies for the coal situation, but, relating the story of the horse down the throat of which the farmer tried to blow some physic and found that the horse blew first, he said that he feared that those who were unfavorably affected by the reforms would blow back so hard that the physic could not be administered.

New England Mineral Crude Oil Receipts

(Gallons)

	1918	1919	1920	1921	1922*
Maine and New Hampshire	24,529,000	23,499,000	40,866,000	27,636,000	30,240,000

Approximately 165 gallons of crude oil is equivalent to one ton of bituminous coa

Prelimnary Statistics of Production of Coke And Byproducts in 1922

Statistics of production of coke and byproducts in the United States in the calendar year 1922, as far as available are summarized in the following tables. The figures are subject to revision of final reports from the producers.

ESTIMATED MONTHLY PRODUCTION OF BEEHIVE AND BYPRODUCT COKE AND OF PIG IRON IN 1922

Month	Beehive Coke (Net Tons)	Byproduct Coke (Net Tons)	Pig Iron (Gross Tons)*a*
Monthly average, 1920	1,708,000	2,569,000	3,077,000
Monthly average, 1921	462,000	1,646,000	1,379,000
January, 1922	496,000	1,882,000	1,645,000
February	549,000	1,796,000	1,630,000
March	732,000	2,133,000	2,036,000
April	528,000	2,202,000	2,072,000
May	436,000	2,539,000	2,306,000
June	460,000	2,589,000	2,361,000
July	446,000	2,496,000	2,405,000
August	531,000	1,818,000	1,816,000

Total	19,750,000	28,493,000	+8,743,000	+ 44

(*a*) Final figures. (*b*) From monthly reports furnished by operators.

Available estimat s on byproducts from coke-oven operations in 1922 are based on the assumption that the quantity of byproducts recovered bore the same relation to the known production of coke in 1922 as in 1921, indicating that the recoveries were approximately: tar, 365,000,000 gallons; ammonia (sulphate equivalent of all forms), 946,000,000 lb.; gas, 447,000,000 M. cu.ft.; and crude light oil, 111,000,000 gallons.—*U. S. Geological Survey.*

Class 1 Railroads Consume 9,736,000 Tons Of Coal in November, at $3.88 per Ton

Class 1 railroads consumed 9,736,000 net tons of coal during November, 1922, as charged to account 394, compared with 8,115,000 tons in November, 1921, according to a report of the Bureau of Statistics of the Interstate Commerce Commission covering 177 steam roads. During the first eleven months of 1922 these roads consumed 85,775,000 tons as compared with 83,994,000 tons during the corresponding period of 1921. The delivered cost per ton in November was $3.88 or 24c. above that for November, 1921. The per-ton cost for the year to Nov. 30 was $3.97 as compared with $4.14 during the corresponding period of 1921.

Fuel-oil consumption continues to gain. During November 155,364,000 gallons were used, as compared with 123,513,000 gallons in November, 1921. The figures for the first eleven months of 1922 and of 1921 were 1,408,291,000 and 1,300,307,000 gallons respectively.

I. C. C. Ignores Wadleigh's Suggestions

The Interstate Commerce Commission has declined in two important instances to follow the suggestions of Federal Fuel Distributor Wadleigh. To meet the anthracite situation in the Northeast, Mr. Wadleigh recommended the issuance of priority orders, which the Interstate Commerce Commission declined to do. This resulted in a flare-up in the House of Representatives, where Representative Treadway, of Massachusetts, cricicised the commission for neither issuing the order nor notifying Congress, if it should have had any doubt as to its authority to take that action. Mr. Wadleigh issued a statement declaring that the priority orders are necessary, in his opinion, but that the commission does not agree and instead has urged the railroad to speed up the movement.

A veritable storm of protest has followed the issuance by the Interstate Commerce Commission of Service Order No. 38. This order instructed the Southern Ry. to assign fifteen cars daily to the mine of the Montevallo Mining Co., at Aldrich, Ala., which were not to be charged against the mine's share of equipment. This action was taken over the protest of Mr. Wadleigh. Mr. Wadleigh contends that the action is not justified by the fuel situation in the South and that it is inequitable to other mines. The National Coal Association, the Southern Ry. and various mine operators have protested against the order.

Ohio River Shippers May Get Long-Desired Nine-Foot Stage in 1924

Completion of three river dams in the Ohio between Louisville and Maysville, Ohio, between now and December, 1924, will make possible a 9-ft. stationary river stage between those two points, according to Major W. W. Parker of the U. S. Engineer's office at Cincinnati, Ohio.

The complete construction of dam No. 40 near Chilo during December, 1924, will furnish the missing link to the 9-ft. stationary river stage, for which river men have agitated since time immemorial. Preliminary operations have already been started, and with best working conditions it is thought work on the dam may be completed before the time expected. The other two dams, Nos. 36 and 38, will be completed this season, according to Major Parker. No. 36 dam is located just above Coney Island, about eighteen miles above Cincinnati, while dam No. 38 is near Rising Sun, Ind.

Finds Coal Moving Faster Than Usual

Despite handicaps of some bad-order equipment as a heritage from the shopmen's strike and of periods of winter weather, the railroads of the United States have been handling coal traffic at a rate in excess of the normal annual movement, according to calculations made by the Traffic Bureau of the National Coal Association. Broadly, west of the Mississippi River coal is seeking a market. Transportation conditions in the South are improving, notably in the Alabama field, the association reports. There continues an acute car shortage in the Appalachian fields, attributed largely to the continued demand for coal. No transportation trouble is reported from the North, excepting that due to weather conditions. No real emergency exists in the bituminous-coal situation from the transportation standpoint, the association reports.

Domestic Exports of Coal and Coke

	Month of December— 1921	1922	Twelve Months Ended December— 1921	1922
Anthracite, tons	306,277	381,758	4,176,221	2,365,187
Anthracite, value	$3,439,541	$4,220,591	$45,624,555	$25,350,677
Bituminous coal, tons	770,092	1,468,917	20,652,827	11,083,112
Bituminous coal, value	$3,831,935	$9,437,765	$122,597,038	$65,891,740
Coke, tons	23,034	123,442	273,888	456,733
Coke, value	$197,700	$849,979	$2,760,939	$4,319,538

Washington Opposes Embargo on Anthracite to Canada As Solution of Northeastern Coal Shortage

Washington, D. C., Feb. 19.—With resumption in Washington of the hearing before the Interstate Commerce Commission in response to a Senate resolution to report on the practicability and possibility of an embargo on anthracite coal to foreign countries, which was begun last week in New York, figures were introduced by the Hudson Coal Co. today showing geographical distribution of its deliveries.

This statement showed that from April 1, 1922, to Feb. 15, 1923, the Hudson Coal Co. delivered 990,620 tons of anthracite consigned to the six New England states; 1,122,526 tons consigned to New York State and 442,876 tons consigned to Canada, besides 460,969 tons for other destinations in the United States. Deliveries to New England from Oct. 1, 1922, to Feb. 15, 1923, aggregated 706,001 tons, being 166,087 in October, 168,179 in November, 175,140 in December, 134,-021 in January and 62,574 in February to and including the 15th. Deliveries to New York State in the same period aggregated 833,482 tons, being 177,665 in October, 205,047 in November, 201,916 in December, 159,348 in January and 89,506 in February to the 15th. Deliveries for Canada in the same four and half months totaled 359,587 tons, being 76,892 in October, 85,019 in November, 92,483 in December, 75,820 in January and 29,373 in February to the 15th.

J. K. McNeilly, assistant to the general manager of the Delaware & Hudson R.R., testified Monday that that railroad has been devoting special attention to coal traffic, particularly since Feb. 2, when its attention was called to local conditions of distress on account of shortage in northern New York. Severe weather since the middle of January and especially since Feb. 1 has caused delay, he stated. Despite this he said that 630 cars laid out at Mohawk terminal Feb. 1 had been reduced to 155 by Feb. 13, and 631 cars set out on twelve sidings had been reduced to 135 in the same period.

D. & N. Car Movement Reported Regularly

A subsequent storm caused further congestion, but voluntary priority given coal last Friday, Mr. McNeilly believed, would relieve the condition considerably. Priority, he stated, might continuously benefit the situation. He testified the Delaware & Hudson R.R. reports its car movement regularly and freely. It was stated at the hearing Monday, which was conducted before Commissioners Campbell and Cox, that while all of the stock of the Hudson Coal Co. is owned by the Delaware & Hudson R.R. only about half of the coal company's product consigned to Canada goes over the D. & H. and that the railroad handles considerable coal, both hard and soft, from other mines.

Following the hearing in New York City on Feb. 14 and 15, Washington officials apparently decided that an embargo is not the proper solution for the coal shortage in northern New York and New England. At the two-day hearing it was the opinion of several witnesses that it would be unwise to place such a restriction on shipments to Canada.

While the hearing was in progress in New York Senator Lodge, of Massachusetts, introduced into the Senate a bill similar to the one previously introduced by Congressman John Jacob Rogers, of that state, authorizing the President to declare an embargo on the exportation of coal whenever he "shall find that the public interest so requires." The bill provides that the embargo may include either anthracite or bituminous coal or both and may be complete or partial.

J. J. Hickey, of counsel to the commission, stated that a subpoena had been issued to the Hudson Coal Co. to furnish data regarding shipments of coal. He said he did not know if it had been served. Walter C. Noyes, of counsel for the Delaware & Hudson Railroad Co.., who was present, said that W. H. Williams, vice-president of the Hudson Coal Co., was on a vacation. He added that the Hudson Coal Co. had not been a shipper of coal for fifteen years, that it prepares and sells its coal at the mines direct to the wholesale dealer. He added, however, that the coal company stood ready to clear up any specific complaint by furnishing any data it has concerning such complaint. Commissioner Johnston B. Campbell, who presided, told Mr. Noyes that the data were necessary if the commission was to make a complete report to Congress.

During the second day's hearing Mr. Noyes promised he would do all in his power to have the data requested ready to present at the hearing in Washington. He was requested by Mr. Hickey also to have an operating official of the railroad present to explain the delay in shipments of anthracite to various points in northern New York State, it having been testified that the movement of loaded coal cars on the D. & H. ranged as high as thirty-five days from the mines to the railroad yards.

Representatives of the New York State Fuel Administration testified that it would require 20,000 tons of coal in addition to the present allotment to relieve the distress now existing in northern New York. It also was stated that the Hudson Coal Co. has promised to aid them in relieving the situation.

New England Receives More Than Allotment

During the hearing E. W. Parker, director of the Anthracite Bureau of Information and director of distribution for the Pennsylvania State Fuel Commission, produced statistics showing that the New England states under the 60-per cent distribution plan agreed upon by the various state fuel administrators was entitled to 3,857,682 tons of anthracite, that upon Jan. 20, 1923, they were entitled to 2,527,456 tons and up to that date had received 2,534,568 tons, or an excess of 7,112 tons, excluding the Hudson Coal Co. tonnage.

Representative Treadway, of Massachusetts, in Congress on Feb. 16 declared that the fuel situation in his state had reached "an acute stage"; that a 60-per cent allotment of anthracite is not sufficient and that the Interstate Commerce Commission should issue priority orders at once.

Congressman Winslow, from the same state, at the same time declared that there is coal enough within reach of New England to satisfy the present requirements if there were only sufficient motive power on New England roads to pull it, in the face of added difficulties because of ice and snow.

Congressman Treadway characterized as false a newspaper report that there were 1,900 cars of coal standing outside of Boston which the railroads were not moving. He said he got his information from the Fuel Administrator.

W. H. Towns, of the Boston & Maine R.R., testifying before the commission, said no embargo had been declared against anthracite shipments on his road. He said storms this winter had been unusually severe and that the temperatures were 3.9 deg. below normal. Mr. Towns furnished statistics showing the number of cars of anthracite shipped over the road from the D. & H. and other roads:

CARS OF ANTHRACITE RECEIVED BY BOSTON & MAINE FROM CONNECTIONS

	D. & H.		All Roads	
	1922	1921	1922	1921
October	3,983	4,527	5,293	5,587
November	4,489	4,001	5,746	4,914
December	4,124	2,883	5,355	4,020
	(1923)	(1922)	(1923)	(1922)
January	4,464	2,918	5,736	3,731
February (12 days)	1,650	1,864	2,376	2,377

R. Van Ummersen, freight traffic manager of the Boston & Albany R.R., compared the shipments of anthracite over his road this winter as follows:

	1921		1922
October	2,132		1,675
November	2,118		1,723
December	1,687		2,103
January (1922)	1,157	(1923)	1,888

Statistics produced by C. L. Bardo, general manager of the N. Y., N. H. & H. R.R., showed that the number of cars of anthracite received from connecting lines and loaded at tidewater points from April 1, 1922, to Feb. 10, 1923, was 42,887 as compared with 61,016 cars handled in the same

way from April 1, 1921, to Feb. 10, 1922, and that during the same periods the total number of cars of bituminous coal handled had been 66,684 and 73,583 respectively. Normal conditions regarding motive power and equipment would be reached, Mr. Bardo believed, in about four months.

In a statement made at the beginning of the hearing Congressman Rogers said that during October, November and December of last year Canada had received 30 per cent more anthracite and 70 per cent more bituminous coal than in the corresponding months of 1922 and that while retail prices for coal in Canada ranged from $15.50 to $16.50 per ton, in New England they ranged from $18 to $30.

He was followed by W. D. B. Ainey, chairman, and James S. Benn, a member of the Pennsylvania State Fuel Commission, who told of conferences held in Philadelphia at which those present, including operators and shippers of coal, decided that as a result of the strike of anthracite mine workers, production for the balance of the coal year could not be greater than 60 per cent and that it was concluded to make the distribution of coal on that basis. At a later conference held with C. A. Magrath and Frederick McCourt, members of the Advisory Fuel Commission of Canada, it was agreed that the Dominion should be placed on the same basis, but Mr. Benn said it was receiving less than 50 per cent of its allotment. He and Mr. Ainey said they felt that the United States was in duty bound to carry out its agreement with Canada.

Mr. Parker's statistics showed the allotment of anthracite for each state and Canada and the tonnage received by each up to Jan. 20, 1923. He said that under the plan of distribution Canada had received up to Jan. 20, 946,785 tons exclusive of Hudson Coal Co. shipments, out of a possible tonnage of 1,310,333 and that its allotment for the 1922-1923 coal year was 2,000,000 tons.

On Feb. 15 a telegram was received from A. P. Lane, Fuel Administrator for Maine, stating that he could get no information from the Hudson Coal Co. or the Delaware & Hudson Co. Railroad Co. regarding shipments of coal into that state.

One of those who declared it would not be fair to place an embargo on shipments of anthracite into Canada was John F. Bermingham, president of the Delaware, Lackawanna & Western Coal Co., who said that so far during 1922-1923 he had shipped 354,000 tons into Canada.

Mr. Bermingham said that on April 1, 1922, he had on Western docks 361,000 tons of coal. He also testified to making the following comparative shipments:

Shipped to	April 1-Dec. 31, 1922	1923 to Date
Illinois	149,000 tons	155,395 tons
Wisconsin	288,000 tons	227,809 tons
Minnesota	151,781 tons	150,916 tons
North Dakota	24,980 tons	19,185 tons
South Dakota	19,540 tons	17,746 tons
Nebraska	15,379 tons	16,231 tons
New York and East	2,339,000 tons	1,403,000 tons
New Jersey	772,417 tons	518,000 tons

At the first day's hearing Mr. Magrath told the commissioners that Canada's average need of anthracite and bituminous coal was 19,633,933 tons and that the average anthracite tonnage shipped into Canada for three years was about 4,000,000. He said that Canada exported to this country about 2,000,000 tons of coal annually, which, comparing the population of both countries, showed that Canada was doing nearly as well as the United States. He declared Canada was the most uniform market for coal operators because of its climatic conditions. Mr. Magrath said about 800,000 tons of Welsh coal had been imported into Canada. He was sure that the present difficulty regarding shipments would be solved satisfactorily and that Canada was always willing to do its duty toward the United States. Replying to a question Mr. Magrath said that the Government of Canada through the Department of the Interior had a committee looking into the fuel question with a view to using soft coal to a better advantage.

STATE DISTRIBUTION OF ANTHRACITE, PEA AND LARGER SIZES

(Showing 1921-1922 shipments, 1922-1923 allotment, total due, total shipped, overages and shortages as of Jan 20, 1923, in tons.)

(Excluding Hudson Coal Co. tonnage)

Canada	4,035,014	2,000,000	1,310,333	946,785		

* These shortages would become an overage of 70,404 tons, if final distribution by states for 441,164 tons of lake tonnage were available. Including this undistributed lake tonnage in the total makes an overage of 538,127 tons, as compared with the 60 per cent allotment up to Jan. 20.

Coal Commission to Probe Violation of Civic Rights

In an announcement issued Feb. 14 the United States Coal Commission states that it construes as part of its duty in ascertaining "the conditions under which coal is produced" and "the causes which from time to time induce strikes," to make a fair and impartial investigation of the controversies which have arisen from time to time between operators and miners, touching what is known in general terms as the civic rights of American citizens. It has been put in possession of certain charges made by miners against operators and operators against miners, but it does not deem the charges and the character of proof heretofore submitted to the commission to be of sufficient value to enable it to reach conclusions upon these subjects.

It is, therefore, calling upon the United Mine Workers of America, the owners and operators of the mines and the public generally who may have any knowledge of the subject, not at second hand but actually ascertained, to submit to the commission in concrete form specific charges of the denial to any American citizen of any right guaranteed to him by the Constitution of the United States, the acts of Congress, and the decisions of the courts thereunder, definitely stating when and where such right was denied, what constitutional or other right was involved, who the witnesses are and where testimony supporting the same is to be found, and what decision of any court has been rendered on the proposition involved.

It also calls for specific instances of the breach of either the civil or criminal law of the United States or any of the sovereign states of this Union, identifying the crime and the criminal, the time and place such offense occurred, the names of the witnesses and their residence, with a statement as to what the testimony of each witness will be on the subject together with a citation of the constitutional principles, the laws enacted thereunder, or the decisions rendered which may have bearing upon the case.

It requests the presentation of the naked facts, unadorned by either oratory or vituperation. Commissioner Thomas R. Marshall has been authorized to examine and analyze all such complaints in order to facilitate their consideration by the full commission.

It asks that in the first instance these charges and briefs be marked in sending for Mr. Marshall, who is not to decide the question but is to collate and lay before the full commission the various propositions touching the rights of person and property, the denial of such rights, and the breaches of the law alleged to have occurred in the coal industry, to the end that the commission may determine what evidence is to be taken upon these questions, when and where, and to the further end that it may be put in possession of all the alleged facts and of the documentary or other evidence proposed to sustain the charges and the briefs, if desirable, of attorneys, upon the law bearing upon the disputed facts.

It welcomes and invites all information obtainable upon these questions.

The commission notifies the operators, the miners and the public that it reserves the right to fix a reasonable time prior to which it will not investigate.

Midwest Operators and Roads Get Nowhere In Car Rerating Parley

How can the evils of overrating coal mines for car allotment be remedied? The question was threshed for two days in Chicago last week without final decision. Several railroads serving Illinois, Indiana and western Kentucky proposed putting a new plan into effect under which a railroad bureau would fix every mine's car rating. Western Kentucky operators agreed it could be done fairly. But Illinois and Indiana disapproved stoutly. Those two states suggested a continuance of the present plan of rating a mine each month on its previous month's performance, adding compromise clauses, to create the proposed railroad mine-rating bureau and give it the power to quiz every doubtful rating and prove that rating by a three-day test run of the mine where necessary, penalizing every mine that failed in such a test. The railroads took the suggestion under advisement for two weeks.

The conference was called by W. L. Barnes of the Chicago, Burlington & Quincy R.R. The only other railroad taking a leading part was the Illinois Central, represented by J. F. Porterfield. The railroads' proposal was that a railroad board or bureau be created to undertake at once the rerating of all mines on the lines affected, the board to consider past production, labor conditions, track facilities and other physical and economic factors in fixing the number of cars to which each mine is entitled. The carriers further proposed that each rating should stand until changed by the board but that any mine owner who felt aggrieved at any time could ask a re-examination and that in case the board did not get around to make it within 15 days, the mine would automatically take a 10-per cent increase until such time as the examination was made.

The Illinois and Indiana operators were agreed to a man that this plan would work great hardships on the mines, first, because ratings might be fixed by men not expert in coal mining, because ratings would be "frozen" and could not be changed within three or four months in spite of rapid changes in mining and markets which regularly require new ratings for many mines, and because tipple hours would not be the basis for determining working time at a mine. There were other objections, but these were the principal ones.

The basic principles in C. S. 31, under which ratings have been determined for some time past, were held by most of the operators to be the best ever devised. Under that car service circular, now in effect, each mine's car rating is determined each month upon the performance of the month preceding. The reports of the mines to the railroads of hours worked is the basis for fixing the normal rate of output.

In the two-day conference the railroads declared there are all sorts of deceptive reports made by mines as to hours worked and other subterfuges resorted to which have increased car ratings in some mines, principally those of southern Illinois, far above a proper allotment. The railroads declared it to be impossible to check up such reports and that all they can do is to accept the reports, false though they may be. For this reason the railroads want to do their own rating.

Some of the operators frankly admitted the charges. Others stalwartly declared they never had falsified reports and never would. It was contended that the roads could easily check up such false reports and correct the evils existing under C. S. 31 if they only would. The trouble is the roads do not and will not police these reports. Thus they permit falsifying by the unscrupulous operators and make it necessary for some of the others to overrate their mines in order to get anywhere near an even break in car supply. It was freely held that C. S. 31 is entirely adequate if properly applied by the roads.

New Basis for Mine Ratings Near

The recent conference on mine ratings appears to be bearing fruit, according to reports received by the Traffic Bureau of the National Coal Association, which indicate that committees of operators and railroad representatives are making progress toward mutual agreements for the formation of new bases for ratings. At present mine ratings are based upon the tonnage loaded per hour, a factor which increases during periods of car shortage and therefore has a tendency to inflate ratings. It was suggested at the recent conference on this subject in Washington that ratings be based on the physical ability of a mine to produce and load coal in an 8-hour day, and reports indicate that agreements along this line are practically within sight.

Charge Jersey Central Directors Restricted Bids for Lehigh Wilkes-Barre Stock

In the hearing now on in the U. S. District Court in Philadelphia into a complaint involving the sale of the stock of the Lehigh & Wilkes-Barre Coal Co. to the Jackson Reynolds syndicate of New York it was charged that the directors of the Central Railroad of New Jersey had "resorted to every means" to restrict bidding for the stock of the coal company so that they might award it to the Reynolds syndicate.

Testimony was given that an offer of $32,259,720 for the stock by the Lehigh Coal & Navigation Co. had been rejected in favor of the Reynolds bid of approximately $31,500,000, and that the bid of the Franklin Securities Co. of Philadelphia was about $2,000,000 higher than that of Reynolds.

The case is an outgrowth of the order of the U. S. Supreme Court that the Reading company and its underlying corporations be dissolved. The objection to the sale of the stock was made by Isaac T. and Mary T. W. Starr, Jersey Central stockholders.

C. J. Hepburn, counsel for the complainants, said that the directors of the Jersey Central, which owned the Lehigh & Wilkes-Barre stock, had disposed of property worth about $40,000,000 to the lowest bidder. He also charged that Reynolds, who was a director of the Jersey Central and the coal company at the time of the dissolution order, had received "inside information," while the data furnished to other prospective purchasers "was meager and indefinite."

Why the Price of Anthracite Has Risen*

The anthracite operators have estimated that the mines would be able to produce between Sept. 11 and March 31 next, the end of the coal year, 60 per cent of the production of the preceding year, and at the joint request of the Federal Fuel Distributor, the Pennsylvania Fuel Commission and the administrators of the several states they designated a Committee on Anthracite Distribution, whose duty it has been to endeavor to obtain an equitable distribution of the tonnage available, giving to each community in each state its proper proportion, the allotments being based on 60 per cent of the tonnage shipped to each community during the previous year.

There are between 15,000 and 18,000 of these anthracite-consuming communities, and there is an average of about five companies shipping to each community. Every operator, with one or two exceptions, makes a weekly report of his shipments to each community and to Canada. These are all combined on tabulating cards and summarized, shippers being advised from time to time of the communities which shows shipments in excess of allotments in order that they could divert tonnage, if necessary, to points where necessities were greater. The tabulating and summarizing of these returns necessitates the handling of some 100,000 recording cards each week.

The matter of the price you pay for your fuel is not so easy to present in an understandable way. Let me assure you of one thing, however, and that is that with the possible exception of some of your articles of food, you are paying as much of an advance over pre-war prices for other commodities as you are for anthracite. A representative in Congress, a few days ago, was making an attack on prices of coal. He was from Massachusetts. A colleague from Indiana told him that the people of his state were complaining bitterly about the price of shoes, but the gentleman from Massachusetts said he knew nothing about that. Shoes are the chief product of Brockton and some other Massachusetts towns. He knew about the prices his constituents paid for coal but he did not know anything about the prices his constituents got for shoes. And relative to the increase in cost of production I doubt if the price of anthracite has advanced in proportion to the prices of other commodities. It seems to affect one more because it is bought by the ton, instead of by the pound, quart or dozen.

In 1900 the actual labor cost per ton of coal produced averaged about $1 for all sizes. At present the average labor cost is between $4.10 and $4.15. In 1900 the average hourly rate paid to all classes of labor including boys, was about 16c.; in October, 1921, the average rate was about 73c., and there has been no reduction since that date. In 1900 the cost of supplies ran about 25c. per ton of output. At the present time the cost of supplies runs about $1.05 per ton.

In 1900 general overhead expense—that is, the cost of administration, office force, sales agencies, local taxes, etc.—did not exceed 25c. a ton. At the present time they are about 61c. a ton. In 1900 the length of the working day was 10 hours. Today it is 8 hours. The contract miner seldom works 7 hours.

That is to say, the price of anthracite stove size at the mine today has advanced 181.3 per cent over 1900, but the cost of labor has increased 311 per cent. The average hourly rate paid all classes of labor increased 356 per cent. The cost of supplies has increased 320 per cent. The overhead expenses have increased 132 per cent. The length of working day has decreased 20 per cent.

These will give you some idea of the increases in cost that have contributed to the cost of your fuel supply, but they do not tell the whole story. You have read recently in the newspapers of the new tonnage tax imposed upon anthracite and consequently upon you if you are a user of anthracite, as I suppose you are. The tonnage tax is only a part in the great scheme of anthracite taxation. This is to be piled on top of other increases.

*Abstract of an address by E. W. Parker, director of the Anthracite Bureau of Information, delivered at the annual meeting of the New York Section of the American Institute of Mining and Metallurgical Engineers, New York City, Feb. 14, 1923.

Alex Drops in Again—for a While

Alex is "in again," or was for a while. No power of the courts nor of the Governor of the sovereign state of Kansas can keep the ertswhile czar of District 14, U. M. W., out of jail for long. Governor Jonathan Davis thought he had the matter nicely arranged a few days ago when he commuted Howat's sentence in the Cherokee County jail. Alex had only recently moved over to the Cherokee County jail from that in Crawford County, from which he had been evicted by a recently elected district judge.

Howat had just got comfortably settled when the Governor interfered. His only ray of hope was in an addenda to the Governor's commutation by Judge Boss of the Cherokee County District Court, to the effect that before he left jail he must dig up $500, the money it had cost the state to put him there. This little detail delayed Alex's adieux somewhat, but on Feb. 12 some miners of the district contributed the money and Alex was out again.

About this time he received word that the State Supreme Court had affirmed a fine of $100 and a peace bond of $5,000 imposed by former Judge Curran of the Crawford County District Court. And on the morning of Feb. 15 the sheriff of Crawford County was awakened by Alex pounding on his bastile gate. Alex again had decided he would rather be in jail than out—with a $5,000 peace bond cramping his style. So he dropped in for a while. On paying his fine he was released, the judge suspending the $5,000 peace bond.

Negotiation of Contracts Lags Because of Uncertainty on Assigned Cars

Some confusion exists among both railroad purchasing agents and mine operators regarding new contracts for railroad fuel which are to be negotiated before the beginning of the coal year on April 1 because of the uncertainty about the assigned-car situation. The assigned-car case is to come before the Interstate Commerce Commission with oral arguments set for March 1, just a month before the beginning of the coal year. It is not considered possible that a decision will be handed down before April 1. If the commission were to abolish the practice of assigning cars for railroad fuel or were to change the practice it would affect contracts which are made on this basis, hence the atmosphere of uncertainty between the parties to these usual contracts.

Coal Commission Expects to Obtain $400,000 Asked; Plans to Complete Work in September

By Paul Wooton
Washington Correspondent of *Coal Age*

Competition is so rampant in the production of coal that price control hardly would be within the range of probability, even were the operators inclined to attempt it. That the President's Coal Commission has reached that conclusion was clearly deducible from statements made by Chairman Hammond and Commissioner Smith during the course of their conference with representatives of the press on Feb. 17. Other important pronouncements on that occasion were to the effect that for the next few weeks the commission would concentrate much of its attention on anthracite matters; that the commission is not in sympathy with the agitation for an embargo on anthracite exports; that sentiment within the commission is stronger than ever against the railroad practice of commandeering coal and that certain coal rail-rate structures need to be scrutinized carefully.

The comment as to price control followed a statement by Chairman Hammond to the effect that the commission intends to study coal prices over a period of several years. Mr. Hammond predicted that certain economies would be recommended which will have an effect on prices, but he said there is no evidence that producers ever have considered any combination with the idea of bringing about higher prices for coal. On the contrary, he said, there is plenty of evidence of competition of the cut-throat variety. Dr. Smith added the opinion that, were operators to agree on a price for coal, some one of them would cut the price before he had been an hour out of the meeting. These points were emphasized to make it clear that the commission's exhaustive study of prices has as its objectives things other than any thought of uncovering a price-fixing conspiracy.

Prior to the settlement of the wage controversy the commission had in mind the issuance of a labor report on March 15. It now is pointed out by Mr. Hammond that the urgency for that report is passed. For that reason it will be formulated more deliberately. On the other hand, the commission must make its anthracite report on July 1. The study which has to be made of that industry, particularly that phase of it which deals with the royalty problem, is intricate and of the greatest public importance. For that reason an increasing amount of attention is to be given to anthracite during the next few weeks. This will not be to the exclusion of certain work which the commission will do on bituminous coal.

Each time members of the commission have referred to the anthracite export situation, attention has been called to the fact that this lies clearly within the jurisdiction of the Federal Fuel Distributor. At last week's conference, however, Mr. Hammond and Dr. Smith showed some disposition to discuss the matter. It was apparent that each of them is entirely out of sympathy with the agitation for the embargo. Reference was made to the slowness which has characterized the utilization by the Northeast of anthracite substitutes. It was pointed out that, even were an embargo laid, it is doubtful whether that section of the country would benefit, due to the transportation situation and to the probability that Pennsylvania would insist on using that surplus at home. Were the Pacific Coast states, which use British Columbia coal, to be convinced that the embargo is being considered seriously, it was predicted that a protest would go up that would eclipse the agitation for the embargo, to say nothing of the stand that would be taken by American consumers of Canadian power, wood pulp and other imports which might be withheld in retaliation.

The presentation made by the Northwestern Coal Dock Operators' Association apparently impressed the commission deeply. Chairman Hammond called attention to the far-reaching effect of railroad-rate schedules on the coal problem as a whole. He was careful to point out, however, that the commission recognizes the Interstate Commerce Commission as the specialist on these matters and that no recommendation with regard to rate structures will be made until full advantage has been taken of the views of that body.

Chairman Hammond admitted that the importance which he attaches to storage amounts almost to an obsession. He strongly commended the public-utility companies for the progress that they have made in establishing a policy whereby most of their plants provide ample storage reserves. Inducements will have to be held out, he said, to encourage such a policy among the small consumers, but the commission expects to find a way that will result in large storage on the part of the railroads. He pointed out in no uncertain terms that there is no such thing as a "right" whereby railroads commandeer coal. It was revealed that Governor Marshall calls this practice "stealing." Other references made to coal commandeering indicate that sentiment against it is well crystallized among the commissioners.

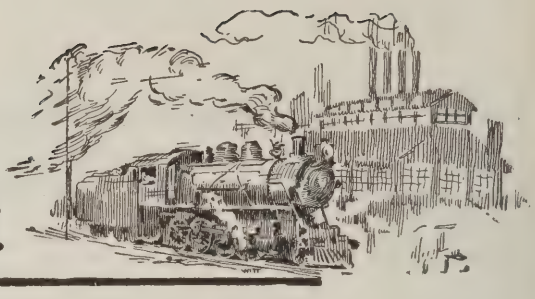
The commission evidently is fully confident that Congress will furnish the additional $400,000 for which it has asked and will pass the amendment to the act covering legal responsibility for answers to questionnaires. Commissioners Hammond and Smith had a satisfactory conference with the members of the House Committee on Interstate and Foreign Commerce and have assurances from the chairman of the Appropriations Committee that their request for additional funds will be granted. It was stated, however, that the plan for prolonging the work of the commission until Dec. 31 had been abandoned. If the additional $400,000 is granted the commission will have been voted a total of $600,000 for its work. This, it was pointed out, is $153,000 less than the original estimate made by the commission's staff. Even with the additional $400,000, it was asserted, it will be necessary to curtail the contemplated investigation to a considerable degree.

Among other things, the commission expects to establish accurately the percentage of foreign labor employed in American coal mines, along with pertinent data in that connection.

One of the points emphasized at Saturday's conference was the matter of public responsibility in obtaining a greater degree of stability in the coal industry. The real problem of the commission, it was said, is to eliminate the peaks and fill up the valleys of the line indicating coal production. If that is done, the consumers must participate in a large way, it was declared.

In response to inquiries, Chairman Hammond stated that he is not considering the acceptance of any Cabinet or diplomatic post. He believes a greater opportunity for public service is presented in the post he now occupies. Moreover, he has devoted four months to this work and he construes it to be incumbent upon him to go through with the task.

Union's Logan Injunction Plea Dismissed



Judge George W. McClintic, in the U. S. District Court at Charleston, W. Va., on Feb. 17 dismissed the petition of the United Mine Workers for an injunction to prevent Sheriff Don Chafin of Logan County and others from interfering with the organization's activities in that county.

Judge McClintic ruled that any of the acts of the Logan County Sheriff complained of were done without authority of the laws of the state and were punishable by the state and that therefore the federal courts had no jurisdiction.

Judge McClintic said he understood the plaintiffs relied entirely on the Fourteenth Amendment to the Constitution in their belief that he had jurisdiction in this case, and quoted at length from decisions holding that the amendments did not apply to individual invasion of individual rights, but only to state action.

Production and the Market

Weekly Review

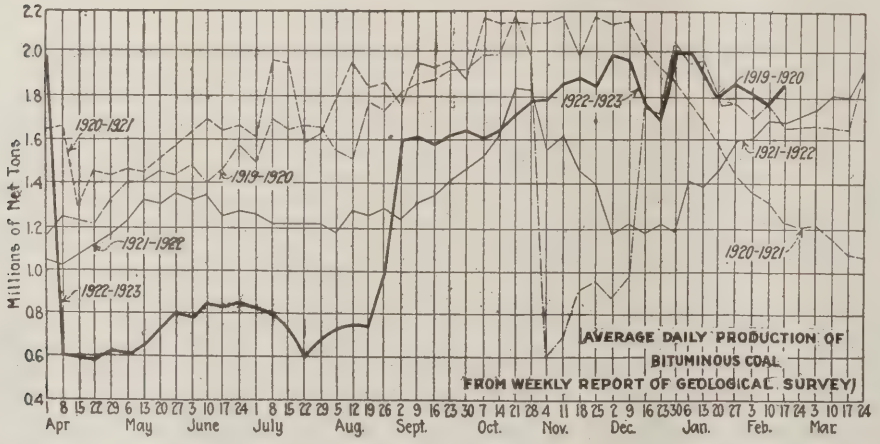
Every dog has its day—so it is said—but this does not appear to be coal's day. While the price of almost every other important commodity is starting a spring ascension, bituminous coal, the fuel of industry and of half the households of the country, is experiencing a steady decline in price. For six weeks, without a break, the *Coal Age* Index of spot prices of bituminous coal has continued the descent. On the first of this week, Feb. 19, it stood at 288, a drop of 8 points from the previous week and of 87 points from Jan. 8, which corresponds to a decline in average price of more than $1.

While soft coal is failing in price, lumber, iron, steel, sugar and many other commodities are steadily going up in price. In fact the lumber producers are reported to have advised their trade recently that they were facing a runaway market, orders and demand far exceeding their ability to ship, because of an acute car shortage. But if soft-coal prices are dragging, consumption is holding up as industrial activity expands and the cold weather holds on. As an evidence of what is happening in those lines that consume steam coal in summer as well as in winter, and that therefore will put a load on the coal-producing industry this year, the following indications may be noted:

Conditions Favorable to Steam-Coal Trade

Railroad loadings overtopped the best previous record for this time of year, the largest production of pig iron in January since March, 1920, the purchase of cotton by spinners in January at a rate never but twice exceeded in any month, both during the war, and with the number of spindles active on Feb. 1 the greatest ever recorded.

Production of bituminous coal remains fairly constant at a figure just under 11,000,000 tons per week, the operators west of the Mississippi report considerable time lost because of lack of market and those in Illinois and Indiana also charge lack of orders with much of the time not worked at the mines. In the East, however, there is yet sufficient demand to give cause for attributing the present lack of full time output by the mines to car shortage.



There is little forward buying of coal beyond the present month, although some have sold as far ahead as the middle of March, particularly of the best southern West Virginia grades. Consumers hold that there is no telling how low the spot market will fall this spring and they are sure to get coal on the open market at better figures this summer than is possible on any contract they can get a producer to sign today. As a sample, it is noted that shippers are asking $3.25@$4 on pool 9 or its equivalent in the Eastern market, but a contract for high-volatile coal has been closed at $2.65.

Inquiries Made on European Shipments

There have been a number of inquiries from abroad for quotations on possible shipments to Europe, and one cargo of 10,000 tons for Italy has been closed. There is much talk in Germany of getting coal needed to replace that cut off from the Ruhr by shipments from this country. While Europe is talking about buying coal here, vessels are bringing English coal into our ports, two cargoes totaling nearly 12,000 tons reaching Baltimore the first week of this month. Any English coal coming in this year was bought last year.

Preliminary estimates for the week ended Feb. 10 indicate that the total tonnage of soft coal raised was 10,836,000 net tons, which is an increase of 150,000 net tons over the revised estimate for the week ended Feb. 3, says the Geological Survey.

Preliminary reports of cars loaded during the present week (Feb. 10-17) show 40,000 cars on Monday, a drop of 32,787 cars on Tuesday, and further decline to 28,428 cars on Thursday. Thus the indicated total output for the present week is about 2 per cent less for the week

Estimates of Production

Calendar year	706,000	2,010,000

(*a*) Subject to revision. (*b*) Revised from last report

preceding, and may be expected to be about 10,600,000 tons.

Continued cold weather has maintained the pressure for anthracite deliveries, and as respects northern New York and parts of New England has greatly accentuated them. Towns on the line of the D. & H. have made numerous complaints to the Fuel Administrator of New York about inability to obtain hard coal. The matter is now well in hand, the Interstate Commerce Commission having interested itself at the request of the Federal Fuel Administrator. Emergency shipments have been forwarded.

Midwest Cuts Prices

By all odds the most interesting development of the past week in Chicago was a drop in the circular on southern Illinois prepared sizes Saturday, Feb. 17, from $5.50 to $4.75. Mine-run held at $3.50 and screenings at $2.50@ $2.75. This drop has been a long time coming but it created a stir of surprise because it broke on a Saturday and because the break came right in the middle of a cold wave scheduled by the weather cracks to last a few more days. Bell & Zoller made the first move at the opening of business that morning. The rest fell in line perforce as soon as they heard about it. A great deal of southern Illinois domestic coal has been selling considerably under the circular for some time, and in spite of the cold wave and a considerable call for coal in small lots from dealers everywhere the association price of $5.50 has been almost impossible to get.

Other prices were not materially affected at once by the southern Illinois cut. Central Illinois list still calls for $3.50 for lump, Fourth Vein Indiana, $4.25@$4.50 and western Kentucky $3.50@$3.75. Dealers' yards have been pretty well drained by a sudden heavy call for domestic coal during the past blizzardy week. They are expected to take on a good deal of coal during the next couple of weeks, especially southern Illinois at the new low price, which includes every size from 6-in. lump down to furnace egg. But spring is just around the corner and nobody looks for any long run of strong business.

All through the Middle West domestic demand has been heavy enough lately to give most mines all the running time they could get cars for, and with screenings thus produced in larger quantity, steam buyers hung back and waited for a softening. In slight degree it took effect in

* Net tons, f.o.b. mines. † Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 288, Week of Feb. 19, 1923. Average spot price for same period, $3.49. This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighed in accordance first with respect to the proportions each of slack, prepared tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

a number of places. It cannot be said the market is strong anywhere in this region. The Standard district east of St. Louis, Mo., felt car shortage probably more than any other region. Even the short lines have fallen down. In the Mt. Olive, Duquoin and Carterville regions mines worked a little less than three days during the week. Railroad tonnage fell off in most Illinois fields.

St. Louis Prices Weaken Too

In St. Louis everything moved hard during the week except Mt. Olive and Standard district. Though domestic demand was fair, the trade did not absorb high-priced fuels from elsewhere. All buying was picayunish. Wagonload trade was a good deal more prevalent than carload business both in the city and in the country. Steam was almost dead. Many small steam plants are picking up the little storage piles they have had on hand, and have stayed out of the market. At the end of the week prices were breaking noticeably.

In that city transportation is a hard problem. Both the Missouri Pacific and the Frisco railroads are hard put for power. Both are borrowing Terminal engines in order to keep the main lines open. Perishable freight is all that gets reasonably speedy dispatch through there. However the Missouri Pacific expects 75 engines out of the Alliance (Ohio) shops soon.

The Kentucky fields worked fair time during the past week, feeling enough domestic demand to absorb about all that was shipped under a 22-per cent car supply on the Louisville & Nashville and approximately 45 per cent furnished by the Illinois Central in the west. On Monday, Feb. 12, the Illinois Central supplied 980 cars out of 1,086 ordered, which was the best transportation performance seen in Kentucky in a long time.

While cold weather created a little better demand for prepared sizes at the same time it was noted that retailers were endeavoring to work yard stocks down and hold them low, with the result that the call was largely for coal at delivery point, or coal that is rolling.

There has been just a little railroad demand with some coal moving to utilities and gas plants, but the demand for gas coal is not especially heavy. Steel-mill demand is light, although consumption is reported heavy, and the big utility buyers probably will be forced back into the market before long, as a result of inroads that are being made on storage stocks.

Screenings are holding up very well in price, due to the fact that there has not been any overproduction, as general industrial consumption has been taking the fuel output. Movement is scattered, going to various sections of the country, but orders are not in large amounts and there is little demand other than for immediate shipment, which is placing the mines almost on a day-to-day basis.

There has been better buying in the South as a result of blizzards extending as far as the Gulf, while an excellent boating stage in the Ohio and Mississippi rivers has resulted in better movement from the west Kentucky field by river, although there are no large river shippers other than the West Kentucky Coal Co.

Northwest Trade Stiffenes

The continued cold and stormy weather kept the domestic business of the Northwest at top notch and stimulated industrial demand some. At the Head-of-the-Lakes prices rose. Splint advanced to $9.50@$10 for lump, $8.75 to $9 for pile-run and $6.75 for screenings with Youghiogheny and Hocking only 50c. off these ton prices. Pocahontas at the Duluth docks is selling for $13 for lump, $9.50 for pile-run and $8.25 for screenings with the supply short indeed. Coke sells for $12. The demand for these two anthracite substitutes is strong. Dealers both there and at Milwaukee are being bombarded by domestic orders they cannot fill. Rough weather has not only delayed all-rail coal but has seriously interfered with receipts by car ferry on the west side of Lake Michigan.

West Remains Tranquil

The stormy cold of last week caused no great hubbub in Utah, Colorado or the coal markets observed from Kansas City. In the mountain states producers found dealers were stocked to care for the swelling demand but that nobody was stocking up for continued cold. Utah slack demand has been heavier than domestic. Mining fields in the mountains as well as in Kansas and Oklahoma having been droning along with market enough to keep prices at the levels of a week ago.

Conditions Firmer in Ohio

A rigid embargo put against connecting lines of the north of the river was the outstanding matter of importance at Cincinnati. Frigid weather to the north and the whole of the immediate valley being caught in the grip of winter has given Cincinnati a chance to catch its breath. There has been a slight stiffening in prices. The market for smokeless coal is stiff. There is more mine-run bringing $4.75 than is being sold at the lower figure, the range being $4.50@$5.

At Columbus weather conditions caused a firmer tone. Buying was stimulated, but the net result was not to advance prices but rather to clean up a lot of coal which was on track. Steam business is slow as consumers are using reserve stocks. Retail dealers are slow to buy, not wishing to accumulate heavy stocks at this period.

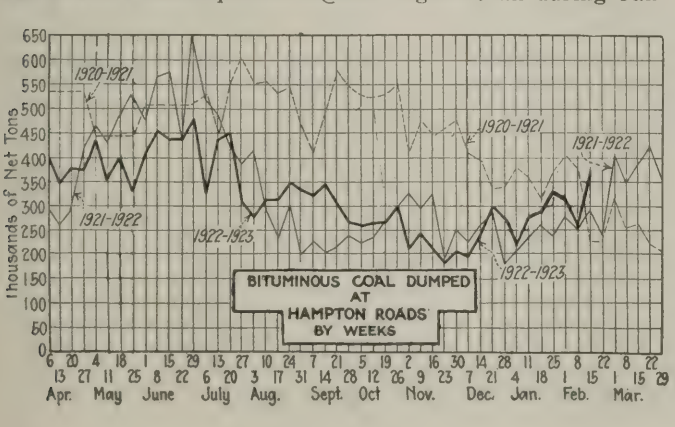
The output of the eastern Ohio mines during the week ended Feb. 10 was 288,000 tons. This was the lowest of any week during the past six weeks, being about 20,000 tons under the preceding week. Receipts of bituminous coal at Cleveland were 2,645 cars, 1,940 cars consigned to industries

and 705 cars to retail dealers. This was a total of 242 cars below the receipts of the previous week. Figures given out by the operators indicate that the mines in the eastern Ohio district are not exceeding 35 per cent of full time because of poor car supply.

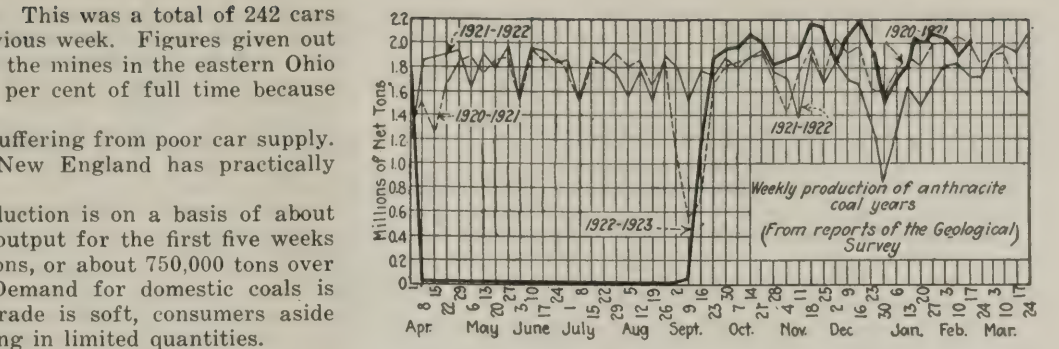
The Pittsburgh district is suffering from poor car supply. Demand for 2-in nut from New England has practically disappeared.

At Birmingham, Ala., production is on a basis of about 385,000 tons per week. The output for the first five weeks of 1923 was about 1,899,000 tons, or about 750,000 tons over the same period in 1922. Demand for domestic coals is strong but the commercial trade is soft, consumers aside from contract customers buying in limited quantities.

Bituminous Moves to New England on Permit



Shipments of bituminous coal to New England are at present moving only on permit, engine fuel alone excepted, and because of the accumulation at Rotterdam Junction the New York Central is even withholding permits for steam coal destined to Boston & Maine points. Receipts of commercial coal, therefore, are unusually light, although for heating purposes permits are freely granted to territory except that served by the Boston & Maine. The demand for water coal is slightly firmer, but when congestion at the Hudson River gateway is relieved the trade looks for much lower prices on Southern coals for inland delivery.



In New England the steam grades are in easy supply except all-rail, and for rail and water delivery, especially via Hampton Roads, quotations are even lower than a week ago. In fact, several of the smokeless agencies have recently made such determined efforts to place spot coal that prices are well down to a $6.50 level per gross ton f.o.b. Norfolk and Newport News. At Mystic Wharf, Boston, the West Virginia grades have offered freely at $9.75, and at Providence $9.25 has been quoted on No. 1 coals for prompt shipment.

Western demand for Pocahontas and New River is reported less insistent, and for that reason the coastwise market is being closely canvassed. Most shippers realize that the March average is reasonably certain to be less than in February and no efforts are spared to place coal that will hardly be mined until March 10 to 15. One or two operating interests have already named a price basis for April, but beyond this there is little disposition to name contract prices for deliveries after March.

Due to transportation difficulties there is a largely increased volume moving via the Philadelphia and New York piers. Gas companies, for instance, have chosen the water route from Philadelphia and New York in order to be assured continuing supplies, and certain of the railroads are taking much more coal by that route than would normally be the case. At Port Richmond January was the largest month for some years, and doubtless other piers would show a correspondingly large tonnage dumped for coatswise shipment.

The continued unfavorable weather has very much delayed movement of steamers and barges, and while a week ago freights were as low as at any time the past season there is enough shortage now of spot tonnage to make rates 10@20c. higher on large bottoms, while light-draft barges are in some cases quoted 25@35c. higher than during January. Receipts here of all grades have shown a marked falling off the past ten days as compared with receipts during January.

New York Buyers Hold Off

Buyers in the New York market are holding off. Operators in some instances are hungry for business. It is believed that some buildings that changed from coal to oil for heating purposes will soon return to the use of coal. In some instances owners of such buildings have made inquiries concerning the possibility of making contracts for coal. Cars at the local terminals numbered 2,327 on Feb. 16, a lower number than in several weeks. Shippers to a large degree have refrained from sending coal forward unless it is on order.

Export coal movement has been renewed from Baltimore, although in light volume, it is true. During January and February four vessels cleared from Baltimore with export coal, the total reaching only 6,768 tons. The largest single cargo was one of 2,649 tons, shipped on Feb. 5 to Havana. Two ships went to Cuba, one to Porto Rico and one to San Domingo. It is noteworthy that not a single cargo went to a European port. The import movement of Welsh coal consisted of 11,478 tons, one cargo being received from Cardiff on Feb. 5 and one from Barry on Feb. 9. This was the first coal importation since Feb. 28 of last year. The coal come to the Consolidated Gas, Electric Light & Power Co., the local lighting corporation. It was explained that this coal was on an old contract, made at a time when the fuel situation was very tight.

Anthracite

Retail dealers in various parts of the West who a few weeks ago cancelled on the belief the coal would not reach them in time to be sold last week asked shippers to reinstate their orders because of the continued cold weather. The producers have no difficulty in moving domestic sizes, but the steam coals are easier.

Production of anthracite showed a small decrease in the week ended Feb. 10. The total output, including mine fuel, local sales and dredge and washery output, is estimated at 2,023,000 net tons on the basis of 38,689 cars loaded as reported by the principal anthracite carriers. Preliminary returns for the first four days of the present week (Feb. 12-17) indicate an output of about 2,000,000 tons.

Coke

The spot market for coke seems to have practically ceased to decline. Quotations are slightly below those of last week. Foundry coke quotations range $8@$8.50. There is a prospect that coke production will increase during the next two or three months, as the high wages in the region probably will prevent men being drawn away for road building and other construction work.

Foreign Market And Export News

Export Demand for British Coals Strong, Production Recedes Slightly

After a week of record-breaking production, the British output for the week ended Feb. 3 was reported at 5,601,000 tons, as compared with 5,644,000 tons the previous week, a decrease of 43,000 tons, according to a special cable to *Coal Age*.

Very strong conditions prevail in the Welsh coal market and the immediate prospects are very rosy. There is no lack of business, and if export facilities are increased the pre-war volume of business will be considerably exceeded.

So far as the Welsh market is concerned there is not any great amount of business actually accruing from the French occupation of the Ruhr coalfield. The European demand is heavy, France continues to buy well, Italy has improved. In the past week some substantial contracts have again been secured, and order-books will be well filled for many weeks to come. Belgium is in the market for heavy quantities of small coal.

In addition to the French and Belgian inquiries, there are also further inquiries from Spain, Holland, Norway, and a number of other foreign countries. South America is a big buyer, while the United States is taking Welsh coal to the extent of between 70,000 and 80,000 tons weekly. An order for 30,000 tons of coal has been placed by the Egyptian State Railways for delivery before March 25, while other considerable business includes coal for the north of Spain railways and for several of the French railway companies.

Market Falls at Hampton Roads

A continued falling market at Hampton Roads produced dullness in the trade, but gave promise of reaching a basis soon on which shippers may compete with British coal abroad. Movement coastwise showed some improvement, while bunker business held up well.

Recent storms delaying shipping caused an unusual store of coal to be laid up at the piers, but this was soon dissipated, and the car situation showed little improvement. General shipping appears to be on the increase, with the consequent boost in demand for bunker coal.

Cut in price of retail coal is thought to be imminent, in view of reduction in prices at the mines. Pocahontas coal is being delivered to dealers here at approximately $9.50, and the retail price is $14, while run of mine coal costs $6.75 on the yards and is sold for $11. The tone of the market was not strong, but prospects were unusually bright in view of the general belief that buying will pick up by March 1.

French Coals Firm

The interruption in the arrivals of German reparation fuel and the violent rise of imported British coal prices have increased the firmness of French industrial coals. There is some rumor of an increase in the prices of the Nord and Pas-de-Calais collieries. There is also a possibility, in the present circumstances, of a reversion to some amount of government control over the French coal trade in view of securing for essential industries and public services, such as metallurgy and railways, a complement of fuel supplies to replace the defaulting German deliveries.

The output of the Nord and Pas-de-Calais collieries is steadily increasing. On the other hand, a strike of the Saar miners is now being threatened, and if this eventuality was realized, a greater rarefaction of industrial coals on the French market would of course ensue.

From Jan. 1 up to Jan. 9, the following tonnages were shipped to France and Luxemburg:

From the Ruhr:	Metric tons
Coal	57.364
Coke	135.795
From Aix-la-Chapelle:	
Coal	3.901
Coke	9.410
From Cologne:	
Lignite briquets	16.841

Since Jan. 10, no shipment was made from the Ruhr; but the following were made from Aix-la-Chapelle and Cologne (also to France and Luxemburg): Aix-la Chapelle (from Jan. 10 up to Jan. 18):

	Metric tons
Coal	1.729
Coke	9.809

Cologne (from Jan. 10 up to Jan. 13):
2.882 metric tons of lignite briquets.

On the other hand the following tonnages of German coke were received by French blast furnaces (the dates hereafter mentioned are dates of arrival, while the above ones were dates of shipment).

	Metric tons
From January 1st up to January 12th	151.500
From January 13th up to January 15th	18.200
On January 16th	4.600
January 17th	1.394
January 18th	603

Since then, no shipment of German coke was received, and a great number of blast-furnaces in the East and in Lorraine are now being blown out.

In December, the quantities of coal received in French seaports were as follows:

	Metric tons
British coals	1,455,645
German coals	99,519
Belgian coals	1,372
Dutch coals	543
Total	1,557,079

News Items From Field and Trade

ALABAMA

The mine of the **United States Coal & Coke Co.** at Lynch celebrated Lincoln's birthday by **breaking the world's record for a day's output.** The tipple poured out 12,820 tons, or 256 gondolas of fifty tons capacity, in nine hours.

The County Coal Co. has increased its capital stock from $100,000 to $200,000. The company operates a mine on a spur of the Central of Georgia Ry. in the Cahaba valley, maintaining offices in the Jefferson County Bank Building Birmingham.

The Buck Coal Co., of Helena, Shelby County, has been incorporated by G. E. Warwick and others, with a capital of $10,000, all paid in and will engage in mining operations in Shelby County.

ARKANSAS

Mine No. 15 of the **Central Coal & Coke Co.** has resumed operations, having been idle since Feb. 4, 1921. The mine has been brought up to date with new equipment, including mining machines.

Settlement has been made of the entry dispute at the Blue Hill mine at Alexander, and on the advice of the arbitration commission work has been resumed.

COLORADO

Governor Sweet is strong for the Moffat tunnel project, which would open transportation facilities to one of the largest coal fields in the world. There is an available coal deposit in the new field estimated at 39 billion tons.

Colorado mines produced 9,140,545 tons of coal during eleven months of 1922 and part of December, 1922.

CONNECTICUT

Governor Templeton has put **Superintendent Robert T. Hurley** of the state police **in charge of the fuel situation** in the state. He succeeds Thomas W. Russell, who resigned as State Fuel Administrator.

DELAWARE

H. G. Horton, of the explosives department of the du Pont company has been named as Western representative of the contractors' division of that department, with headquarters in the McCormick Building, Chicago.

GEORGIA

T. I. Cleary, who recently opened an office in Atlanta for the sale of power-plant equipment, has been appointed Southern agent of the **Combustion Engineering Corporation.**

ILLINOIS

The Clover Leaf Coal Co. has been incorporated by Ralph B. Mitchell, H. W. Ragle and Wm. H. Warder. The capital is $150,000. Mitchell is in charge of the Cosgrove interests at Marion and Warder is attorney for them.

Officers of the Silver Creek Colliery Co., Galesburg, have been elected as follows: H. W. Stewart, Monmouth, president and treasurer; W. D. McCollough, Monmouth, vice-president, and George C. Gale, Galesburg, secretary. Ten years ago the company operated one mine with a production of 200 tons of coal daily. Now its two mines can produce 2,000 tons daily. The mines are electrically equipped and are among the best in Fulton County.

Drilling for coal will be begun soon in the fields **north of Edwardsville.** The first drill will be put down in Big Mooney Hollow, northwest of Edwardsville. Judging by the mine of the Newcastle Coal Co., it is probable that the hole must be sunk between 150 and 180 ft., to get coal. The Newcastle mine is 180 ft. deep. At least a dozen other holes will be drilled on farms upon which options have been secured by Edward Gaertner. The options were obtained on approximately 10,000 acres of land and tests will be made at a number of spots over the area.

Harvey Sconce, of Sidell, **has leased over 2,000 acres** of coal lands near that village. Four test drills have been put down in different sections of the leased area and several good veins have been discovered.

George F. Campbell, C. F. Hamilton and R. Crawford have incorporated the **Pyramid Coal Co.** at $225,000 to mine and handle coal.

Harry N. Taylor, of Chicago, head of the United States Distributing Corporation and who has succeeded Peter Kooi as president of the Sheridan Wyoming Coal Co., made an inspection trip through the Wyoming properties during the latter part of February.

An electrification program at the Moffat mine of the Moffat Coal Co., at Sparta, has been carried forward by the installation of a 525-kva. generator driven by a 26 x 32 in. Corliss engine in a new section of the power plant. Alternating current at 2,300 volts is transmitted along the surface and down a borehole a mile from the plant to three 150-kw. motor generator sets placed advantageously near the working faces which supply cutting machines with direct current at 275 volts. The main generator supplies current also for three pumps underground—two rotary portables and one duplex, which bring the water to the steam pump at the bottom—and to a 40-hp. motor driving the shaker screens and a motor of half that size in the shop building driving a power saw, emery wheel, drill press, bit sharpener and two power hammers. A 202-ft. brick stack built last summer attracts attention to the plant. Other improvements may be made at the mine soon.

Fire recently destroyed a portion of the top works of the **Jackson Coal Co.** at Hallidayboro, the cause of the fire being unknown at this time. The combination blacksmith and machine shop was totally destroyed while adjoining buildings were damaged. W. D. George is superintendent of the plant with offices in Hallidayboro.

The Joseph P. Rend Co., of Chicago, has filed articles of incorporation with a capital of $1,500,000 and will mine and deal in coal, oil, gases and the like. The incorporators are Joseph P. Rend, James E. Rend, George B. McKibbin.

The Ernest Coal Co., of Marion, has installed Nolan automatic cagers, of the style having two sets of horns, at their Pittsburg and Johnston City mines.

E. S. Van Sant is retiring from the coal business. He has already withdrawn from the **Globe Coal Co.,** of Chicago, of which he was vice-president and has sold his interest in that company. He is also to leave the **Eureka Coal & Dock Co.,** of Chicago. He has been a vice-president of that concern also.

Executives and mine officials of the Union Colliery Co. were banqueted recently at the St. Nicholas Hotel, Duquoin. The event is an annual one and was enjoyed by everyone who attended. Dr. L. E. Young, president, and E. S. Stevens, chief auditor, both of St. Louis, were present at the banquet, the former acting as toastmaster throughout the evening.

Reports have been confirmed that the **Lumaghi Coal Co.** of St. Louis **will soon sink a new coal mine near Johnston City.** The new mine will be started on a location on the James Hartwell farm near Johnston City and work will probably be started in a few weeks. First reports were that the St. Louis Coke & Chemical Co., which concern makes coke and byproducts from Southern Illinois coal at its Granite City (Ill.) plant, was going to finance the sinking of the new mine but these have proven false. A. B. Dowell, of St. Louis, has obtained the contract for the sinking of the shaft.

INDIANA

Suits have been filed at Petersburg **to foreclose mortgages** on coal property held by the Vulcan Coal Co. Seven suits were filed by farmers who had contracted to sell about 1,000 acres of good stripping property to the company, which was to pay a third of the purchase price in money and give a first mortgage on the farms for the other two payments. The farmers allege the payments are overdue. The farmers seek to recover the land so that they can sell it to other coal companies.

The **Bogle mines, No. 1 and No. 3,** near Blanford, seven miles west of Clingon, **have been sold to the Binkley Coal Co.** The Binkley company bought the Pine Ridge mine, near New Goshen, from the Bogle company about two years ago. The company owns another mine in the Herrin field. Since the death about a year ago of Mr. Bogle, his properties have been in the hands of an administrator. Henry Stark, formerly secretary of the company, has been president. He is to go with the Binkley company as sales manager under R. B. Starek, vice-president. Mahlon B. Stark, of Clinton, a brother, is manager of the two Bogle mines and it is reported will remain in that capacity. These mines employ about 1,000 men. A new preparation plant is to be installed at the No. 1 mine.

The Linton Summit Coal Co., Linton, raised 2,343 tons of coal in 1,087 hoists on Feb. 8. This is the more remarkable when the primitive conditions at the mine are realized. It is a one-sided mine with a single loaded and single empty track shaft bottom.

The Mt. Pleasant Coal Co., of Terre Haute, has increased its capital stock from $25,000 to $50,000.

Coal operators of Indiana are considerably elated over the decision of the Indiana Supreme Court knocking out the legislative enactment of 1913 under which employers must pay twice a month and in cash. The hold-up evil has been severe of late, and there have been numerous cases where payrolls were stolen, with the result that employers in various lines have been anxious to see a decision on a test case. In fact some of the employers at some points were steadily violating the law. They argued that a check was merely an order on a company treasurer for cash and that the bank as a depository of the company drawing the check was acting as treasurer.

IOWA

The Adelphi Coal & Mining Co., Des Moines, has been incorporated with capital of $50,000 by B. B. Hulsman, president and treasurer; B. F. Foreman, vice-president; R. H. Cook, secretary, and Frank L. Hall, assistant secretary.

To protect Sioux City coal consumers, the dealers of the city who are members of the Coal Exchange have under consideration a plan whereby **all dealers will adopt an emblem guaranteeing the weight** and quality of all coal delivered. This plan follows that adopted in many other cities.

The Pearson Coal Co., Clarinda, is opening a new mine west of that city. A switch track will be built to connect with the Tarkio branch of the Burlington R.R.

KANSAS

Part of the top works, including fan house and cribbing to the bottom of the airshaft, were **destroyed by fire** recently at mine 21 of the **J. R. Crowe Coal Mining Co.** Possibly two months will be needed to rebuild.

H. P. McCaustland is trustee for a syndicate to develop a part of the 20,000-acre coal field in Clark County, 16 miles west of Bucklin.

The Tulsa County Coal Co. has been incorporated for $50,000 by B. C. Connor, H. O. Tallman and E. E. Henning. They have acquired a large acreage near Pleasanton.

Robert Howell, a shotfirer, was killed and Mine No. 16 of the Jackson Walker Coal Mining Co., at Capaldo, near Pittsburgh, was badly damaged by an explosion resulting from a **"blow-through" shot,** Jan. 31. James Sherwood, Kansas state mine inspector, discovered that the shot that caused the explosion lacked only 6 in. of being drilled through into an adjoining room. The shot, heavily charged with black powder, ignited gas and dust in the mine, and timbers were set fire more than 600 ft. away.

Frank Schopflin was elected vice-president of the Central Coal & Coke Co., at Kansas City, Mo., Feb. 7, to succeed Harry N. Taylor, who recently resigned to become head of the United States Distributing Corporation. Mr. Schopflin came to the company in 1902 as an assistant to the president, C. F. Keith. During the last year he has been general manager of the lumber department of the concern. Whether Mr. Schopflin eventually will assume the duties performed by Mr. Taylor, who was active directing head of the coal department of the company, has not been announced. For the present, various heads of departments in that branch of the firm's activities are reporting directly to Mr. Keith. Before entering the service of the Central Coal & Coke Co., Mr. Schopflin was in the Kansas City offices of several railroads.

A co-operative organization of miners, operating under the name of the Osage City Labor Exchange has **purchased the mine of the McCune Coal Co.**, near McCune. The organization had been operating the mine six months under lease. It plans to sink a second shaft early this spring in order to extend development of the mine without violating a Kansas law which limits the number of men employed in a single shaft mine.

Two damage suits for personal injuries which resulted from pit cars running wild down inclines of strip mines and striking workers were filed recently in District Court at Pittsburgh. One, for $7,623.48, against the Mackie Clemens Coal Co., was filed by Asa Musgrove, a general utility man. The other, for $5,541, against the Pittsburgh-Oskaloosa Coal Co., was filed by Fred W. Kirk, a track layer.

KENTUCKY

The Virginia Coal & Coke Corp., a new organization with headquarters in Roanoke, Va., is contemplating **extensive development in the eastern Kentucky coal fields.** It is said the firm will spend $1,000,000 in development, part of which will be done in Harlan, Perry and Letcher counties. It is reported the company will build a branch line in Harlan County, while in Letcher County the main development will be in the Elkhorn field, arrangements for workings there already having been consummated.

The Edyth Coal Co., of Beattyville, which was recently incorporated for $20,000, has organized with Robert Jameson as president-manager and Beatrice Jameson as secretary-treasurer. The company has taken over the properties of the Sturgis Creek Coal Co. and will develop 600 acres of coal land at Idamay. The company expects to have a daily capacity of 400 tons of coal and has purchased the equipment necessary to carry out the development work.

The Kentucky Cooperative Coal Corporation has been incorporated at Lexington, with a capital of $30,000, and C. C. Perry, C. R. Taylor and Ernest C. Brown as the incorporators.

The Flynn Coal & Coke Co. has been incorporated at Sunnyside by D. K. Flynn, H. B. Beury and A. S. Guthrie with a capital of $50,000. The post office address of the company is Grafton, W. Va.

The Morganette Coal Co., which was recently incorporated at Morganette, has perfected its organization with the election of the following officers: President and manager, T. R. Ragland; secretary, C. O. Dunn; treasurer, W. A. Stanley. The company has taken over the leaseholds of the Hawley Coal Co., the Combs Coal Co. and the W. E. Griffiths Coal Co., all in Fayette County. The company has about 1,600 acres under development and the present output is about 500 tons a day.

The Fire Creek Pocahontas Fuel Co. has been incorporated at Huntington with a capital of $150,000. The incorporators are H. A. Smith, of Mt. Hope, and G. T. Smith and William G. Harvie, both of Huntington.

The Coal Exchange Co. has been incorporated at Covelle, with a capital of $500,000, and with D. C. Schonthal, W. E. Deegans and G. D. Miller as the incorporators.

The Coe Pocahontas Coal Co. has been incorporated at Covelle, with a capital of $200,000, and has its post office address at Romney. The incorporators are E. J. McQuaid and C. E. Lilley, both of Bluefield, and H. D. Smith, of McComas.

T. P. Colgan, of Middlesboro, has been employed by the State Tax Commission to collaborate with J. L. Smith, of Danville, in making a survey of the coal fields for tax assessment.

Amended articles of incorporation have been approved by the State Department at Frankfort for the **Amburgy Coal Co.**, Louisville, with mines in eastern Kentucky. The capital has been increased from $175,000 to $225,000. **The name has been changed to the Letcher Coal Mining Co.**

Whitesburg reports that the **Elkhorn and Hazard fields are again humming** with coal production, after a temporary tie-up as a result of landslides on the B. & O., which dammed up Elkhorn Creek, flooding several mining towns and closing down the Consolidation Coal Co., and many other big operations, until the B & O. was able to clear the tracks. It took the better part of a week to get the road open again. It is reported that mines in that section are getting a good car supply and are quite busy.

The Southern Coal Co., has filed suit in the Jefferson Circuit Court, Louisville, **against the Mountain Gem Coal Co.**, asking for damages of $3,238.07, alleging that breach of contract in failure to deliver fifty cars of coal. The buyer claims to have been forced to take a loss of the amount sued for in filling orders from the open market.

Western Kentucky Democratic leaders meeting at the Watterson Hotel, Louisville, **proposed to run James R. Rash**, of the St. Bernard Coal Co., Earlington and Madisonville, **for governor** of the state, and showed opposition to other western Kentucky men who have been mentioned as possible candidates. The meeting also favored a general income tax for the state instead of a coal tonnage tax, as is being argued in some circles.

State militiamen are in charge of the situation at Corbin, where there has been considerable violence, the town having been unsettled ever since the railroad strikes last summer. Corbin is a big junction point of three branches of the Louisville & Nashville R.R., and a shop town. The company never gave in to the unions, and miners in the district and loafers sympathized with the railroad workers. A curfew law has been passed by the council, and an effort is being made to clear up the situation. A workingmen's boarding house was recently dynamited and several men have been shot. This is an important point to coal operators of southern Kentucky and Tennessee.

MISSOURI

Mining permits have been granted by the Circuit Court at Huntsville to the **Black Diamond Coal Co.**, of Huntsville, and to **John Lumb**, of Huntsville, both of whom furnished bonds. Mining activities have increased in the western part of Randolph County to such an extent that new mines will be opened and operations of several old shafts resumed in the near future.

Initial steps have been taken at Huntsville **to open another coal field** and men employed at the Powhattan mine have taken the initiative and it is believed that the business men of the city as well as the Chamber of Commerce will assist in the project. It will be necessary to build a track, considerable trestling and tipple to the new field and the miners have generously signed up to donate a week or more of their time to accomplish the job.

A local syndicate is forming to **exploit the coal acreage around Prairie Hill.** Reports have it that a number of shafts will go down this spring.

NEW JERSEY

Halden-Kelley Coal Co., Inc., Clearfield, Pa., announces the opening of a branch office at 38-40 Clinton St., Newark, N. J.

NEW YORK

Justice Lydon in the Supreme Court of Manhattan has **set aside a verdict returned by a jury last month against Willard, Sutherland & Co.**, bunkering contractors, in favor of the old Tidewater Coal Exchange. The action was brought by Receiver Coyle of the Tidewater Exchange to set aside certain settlements between debtor and creditor members. In his opinion Justice Lydon stated that the jury's verdict was clearly against the weight of evidence submitted by Willard, Sutherland & Co., that the latter's accounts with the old exchange have been completely balanced, and that the exchange has no claim whatever upon Willard, Sutherland & Co.

Douglas M. Deringer, for several years fuel engineer with the New York Central R.R., has resigned from that company and become associated with Dickson & Eddy, New York City.

Raymond O'Brien, formerly of the Allan Coal Mining Co., has been engaged as manager of coal and coke sales of the Iron Trade Products Co., of Pittsburgh, Pa., for the New York district with headquarters at 30 Church St., New York City.

OHIO

As a result of a recent decision of the State Supreme Court, holding that the Southern Ohio Power Co., of Maine, operating the big electric power station at Floodwood, Athens County, and supplying current to a number of Hocking Valley municipalities, cannot operate in Ohio, reorganization is proposed whereby a new Ohio corporation known as the Southern Ohio Power Co. is to acquire the properties of the old Maine corporation and the various distributing companies. The court held that the Maine corporation is in fact a public utility because of the interlocking directorates with the distributing companies it sells its current to, and under Ohio laws no other than an Ohio corporation can engage in the electric light and power business. Application to the State Public Utilities Commission to approve the reorganization plans calls for an issuance of $3,200,000 by the new Ohio corporation to be exchanged for assets of the other companies, estimated at that value.

The Cantwell Coal Co., Bridgeport, has been chartered with a capital of $10 000 to mine coal in the Pittsburgh No. 8 district. Incorporators are John E. Barth, Robert Barth, William Rennis, Jacob Barth and Martin Cantwell.

The tipple of the White Coal Co., located near Bellaire, was **destroyed by fire**, entailing a loss of $7,000. Just a day previous the **warehouse** of the Pultney mine of the Cambria Collieries Co. was **destroyed by fire** causing a loss of $5,000.

James C. Layne, Jr., Cincinnati; Albert E. Scherm, Cincinnati; Joseph G. Walton, Pittsburgh, and John Daker, Cleveland, have been admitted as partners to the firm of Eaton, Rhodes & Co., Cincinnati. William G. Eaton and Frank R. Rhodes are the other members of the firm.

OKLAHOMA

Prospecting for location of coal goes on **along the Oklahoma-Kansas line.** The latest acreage is in the so-called Angola field, which is independent of the Edna-Welch field. Favorable reports come from the drillers all over Labette County. The two heavy leasers in the new fields around Welch are the Central Coal & Coke Co. and the Hartford Valley Coal Co. Railroad extensions are to be put through this spring. The Central Coal & Coke Co. is reported to have paid in cash for leases more than $25,000 for acreages near Hollow, Okla. In the Quapaw territory report has it that the Charles M. Schwab interests have leases on 2,700 acres, and $25,000 to $30,000 has been spent by the agents of these interests.

The Oak Ridge Coal Co., capital $200,000, has been organized by Vince Davis, Ray Morgan, James Hilling and others, to sink a mine at Red Oak.

PENNSYLVANIA

Louis J. Bradley has joined the Keister-MacQuown Fuel Co., Pittsburgh, as Eastern sales manager. Mr. Bradley has been actively identified with the bituminous trade since 1909. Starting as weighmaster at the Edna Mine of the Pittsburgh & Baltimore Coal Co. in Westmoreland County, his early training carried him through the various positions of inspector, shipper, mine clerk

LOUIS J. BRADLEY

and superintendent of the mine to the position of Eastern representative for the United Coal Co. with headquarters in Philadelphia, Pa. With this company he was identified until it was disbanded, when he joined the Quemahoning Coal Co. During 1917-18 he was engaged in war work, resuming coal work at the close of the war. The Keister-MacQuown Fuel Co. plans to engage extensively in export business.

The following bituminous coal companies were recently incorporated at the State Department at Harrisburg: **Baton Coal Co.**, Pittsburgh, $50,000; Chester J. Nicklas, W. W. Booth and George S. Baton, Pittsburgh, incorporators. **Mt. Hope Mining Co.**, Kersey, $10,000; A. C. Hau and W. G. Hau, Kersey, Pa., and Joseph J. Szukalski, Buffalo, N. Y., incorporators. **Walnut Hill Coal Co.**, Connellsville, $10,000; Louis Hetzel, John Swope and William G. Duncan, Connellsville, incorporators.

A state charter has been issued to the **George H. Foster Coal Co.**, Pittsburgh. The capital stock of the company is $25,000 and E. E. Beardsley, Point Marion, is treasurer and one of the three incorporators, the others being George H. Foster, Pittsburgh, and H. E. Hackney, Uniontown. The purpose of the corporation is the mining and producing of coal and the manufacture of coke.

Since the No. 7 breaker of the Susquehanna Collieries Co. burned down Feb. 6 the company is making arrangements to prepare the coal at its Glen Lyon Mines and hopes to have the colliery in operation soon.

Fourteen hundred men went on strike Feb. 13 at the Kaska Williams colliery of the Lehigh Coal & Navigation Co. as a result of a dispute over wage rates and mining conditions. Approximately 8,300 men at the other fourteen collieries of the company had walked out on the preceding day for the same reason. Three thousand mine workers in the Mt. Carmel district quit Feb. 12 at the Reliance and Alaska collieries of the Philadelphia & Reading Coal and Iron Co., in sympathy with the miners at Locust Spring, who claim that men working in slopes received $8.01 a yard at one place and $11.03 for the same in another. District officials of the Miners' union are making an effort to settle the difficulty. They declined to state whether the strike had the sanction of the union.

Three thousand anthracite mine workers employed by the Susquehanna Collieries Co. at Nanticoke and Glen Lyon struck Feb. 16 because of local grievances. One of the complaints is that the company is asking the men to pay 90c. a ton more for coal, due to the fact that a breaker had burned, compelling the company to haul the fuel a longer distance.

The following officers and directors of the mining section of the **Engineers' Society of Western Pennsylvania** have been elected for the ensuing year: Chairman, H. M. Eavanson; vice chairman, E. H. Coxe; Directors, J. O. Durkee, J. R. Elliott, M. D. Gibson, J. M. Rayburn and E. S. Taylor.

The following bituminous-coal companies were granted charters at the State Department at Harrisburg recently: **Ramsey's Run Coal Mining Co.**, Indiana; capital stock, $50,000. **Appalacha Coal Co.**, Pittsburgh, $150,000. **Anderson-Rees Coal Co.**, Pittsburgh, $15,000.

Representative David Fowler, Lackawanna County, on Feb. 7 introduced a bill in the House **to repeal the anthracite tax law.** The bill is similar to that offered the week before by Representative Wilson G. Sarig, Berks County. Thirty-five members from the anthracite regions of the state have formed an organization which will work for the repeal of the tax. The new organization will ask the House Ways and Means Committee for a hearing on one of the two identical repealers now before that committee and will urge that one of the bills be reported out affirmatively.

A bill prohibiting understandings and agreements which would prevent, restrict, obstruct or delay the sale or delivery of coal and making it **unlawful to refuse the sale or delivery of coal** was introduced in the State Senate Feb. 12 by Senator George Woodward, of Philadelphia. Persons who violate the provisions of the measure are guilty of a misdemeanor and upon conviction shall be sentenced to pay a fine of $25 for each ton of coal the sale or delivery of which was refused or delayed. The bill relates to dealers and officers of coal companies and also to partnerships and officers of corporations engaged in the operation of any mines or collieries.

The Senate bill providing for grading of coal was **reported out of committee this week with an affirmative recommendation** and passed by the Senate on first reading. When it came up in its second reading stage on Feb. 13 it was recommitted to the Judiciary General Committee.

Representative David Fowler, Lackawanna, has introduced a bill in the House **amending an act of 1921** relating to the examination of inspectors in the anthracite mines. The measure increases the maximum age of applicants from fifty to sixty years.

Indications that there will be **no mine-cave legislation put before the Legislature this year** by members of the House from the anthracite district of the state. It is said that local efforts will be made to meet the surface subsidence trouble.

The end of the Stavitsky bill, prohibiting sheriffs from aiding in quelling riots and disturbances without a call from local police authorities, came soon after it was introduced. The House Law and Order Committee reported it out during the past week with a negative recommendation.

The Bethlehem Steel Co. purposes building a new battery of coke ovens at its Lackawanna plant.

Attorney George R. McLean, of Wilkes-Barre, has been named a director in the Lehigh & Wilkes-Barre Coal Co., to succeed the late H. H. Ashley.

The Jefferson & Clearfield Coal & Iron Co., of Indiana, Pa., has declared a dividend of $1 a share on the common stock, payable Feb. 15 to stock of record Feb. 13. This is the first dividend ordered on the common stock since November, 1920, when a disbursement of $8 a share was made, which was the first distribution since 1905. A stock dividend of 150 per cent was distributed Jan. 18, last.

RHODE ISLAND

State Fuel Administrator George H. Webb has received **many complaints of inferior coal** sold in that state. Seventeen samples taken from the bins of firms against whom complaints had been made showed that the combustible material ranged from 40.5 per cent to 76.4 per cent.

UTAH

The U. S. Fuel Co. has appointed **A. D. Pierson**, formerly of the Utah Fuel Co., fuel agent in charge of railroad tonnage.

Following urgent requests from numerous farmers' organizations in Idaho, the Denver & Rio Grande Western Ry. and Oregon Short Line have established **a special emergency rate on coal from Utah mines** to various points in the Gem state. The rate will average about 50c. lower than at present, with the present rate on slack as the minimum in each instance. The new rate is an emergency measure and is designed specially for Idaho farmers. It will also have the effect of lessening the advantage Wyoming mines now have over Utah mines in this field.

It seems that the law passed six years ago setting up a Public Utilities Commission will not be repealed though it is likely to be modified. There is a feeling, a canvass of the legislators shows, that the public would be left without adequate protection if the commission were abolished. Senator Peters, of Brigham City, has introduced two bills on the subject, in addition to the one by another legislator which would repeal the act. One of the new bills would make it compulsory for municipalities to have a representative at all rate hearings and other business affecting price or quality of service. The other bill would take from the commission the power to create a monopoly by granting but one person at a time the privilege of conducting transportation service over the roads of the state.

WEST VIRGINIA

W. E. Hatfield, H. H. Randolph and W. H. Bronson, of Williamson, have incorporated the **Pigeon Creek Coal Co.**, at Bias, with a capital stock of $50,000.

The Millstone Coal Co. has been incorporated at Burch, with a capital stock of $10,000. The incorporators are G. W. Hatfield, H. H. Randolp and G. T. Conley, of Williamson.

J. A. Adams and W. R. Harris, of Morgantown, and D. C. Evans, of Uniontown, Pa., have incorporated the **D. & A. Coal Co.** at Morgantown, with a capital of $25,000.

John Laing, president of the Morrison Coal Co., of Charleston, has announced that the company has under contemplation the **purchase of 4,600 acres of coal land** in the Winding Gulf district.

The Glenbar Coal Co. has been formed at Clarksburg, with a capital of $100,000. The incorporators are L. O. Knipp, of Philadelphia; C. Valdois, of Clarksburg, and C. M. Knipp, of Glenside.

T. W. Miller and C. B. Cushwa, both of Youngstown, Ohio, have become associated with A. M. Cunningham, of Elkins, in the incorporation of the **Rich Mountain Sewell Coal Co.** at Elkins with a capital stock of $75,000.

The Morganette Coal Company at Beckley, W. Va., has been incorporated for $400,000 and has as its incorporators J. Q. Hutchinson, J. R. Ragland, and C. H. Meador.

The Morrison Coal Co., of McGraws, of which John Laing, of Charleston, W. Va., is president, **is purchasing mine motors, machines and cars**, preparatory to developing coal lands. The company has under development 4,600 acres, which promise an output of 1,500 tons daily.

The McKone Coal Co. has been incorporated at Tunnelton, with a capital stock of $200,000. The incorporators are J. J. McCone, L. H. Borgman and F. W. Borgman.

Charles Prafeta and D. A. Ritchie, of Fairmount, and Charles Canarata, of Uniontown, Pa., have formed the **Prafeta Coal Co.** here, with a capital of $10,000.

The Shady Fuel Co. has been incorporated at Oxley with a capital of $25,000; J. A. Lilly, A. A. Skaggs and J. H. Wilson are the incorporators.

Not since 1918, when 27,576,710 tons was handled, has the Chesapeake & Ohio been able to move so large a tonnage of coal as it did during 1922, when **25,703,490 tons were transported** to market from the five great coal fields on the general western division of the road.

The Virginian Ry., it is understood, **will convert into coal-carrying cars several hundred stock cars** which have been lying idle since the war. The Government acquired the stock cars for the Virginian during the war at a cost of approximately $2,000,000 and threw them back on that road after the war was over. As the road has no cattle shipments to speak of, it is proposed to scrap the bodies of the cars and utilize the running gear alone, constructing steel box cars.

Fire destroyed the tipple at the Hickory Camp mine of the Paint Creek Coal Mining Co. about the middle of January, three dwelling houses adjoining the tipple also being destroyed. The fire had its origin in one of the three dwelling houses. Until a new tipple can be constructed the mine will be closed down.

Announcement has been made by Secretary A. H. Crane of the West Virginia Coal & Coke Co., of the appointment of **J. W. Bischoff as vice-president and general manager** of the company.

WISCONSIN

The Packard Coal Mining Co., of Columbus, Ohio, announces the **opening of a Northwestern office** in the New First Wisconsin Bank Bldg., Milwaukee, in charge of Charles Becker.

The Reiss Steamship Co., an auxiliary of the C. Reiss Coal Co., of Sheboygan, **has placed an order for a new steel steamer.** This will make the company's fleet consist of ten steel vessels, with a combined capacity of about 85,000 tons. The steamers are employed by the coal company, which maintains coal docks at Sheboygan, Manitowoc, Two Rivers, Green Bay, Ashland and Superior, Wis.; at Escanaba, Mich. and Waukegan, Ill.

The warehouse and coal sheds of the **Saul Sinaiko Coal & Fuel Co.**, at Madison, burned early on the morning of Feb. 6, causing a loss estimated at $25,000.

CANADA

Men at all the mines in the Drumheller field went on strike on Feb. 1, following a reduction in the number of men employed at the Hy-Grade collieries. The miners demanded that the men at Hy-Grade be kept on the payroll and that the work be distributed among them proportionately, a course that the management refused to adopt. On the morning of Feb. 2 all pits were picketed, and miners were not allowed to go to work. Robert Livett, of the International Board of the United Mine Workers, came up from Calgary, and ordered the men to go back to work, an order with which the men refused to comply. Mr. Livett stated that some drastic course would have to be taken to discipline the men. There is a large quantity of coal on the tracks, so no serious shortage is feared, unless the strike should be a long one.

The Canadian Pacific Ry. completed a branch line last November from Acme to Drumheller, Alta., and since then **there have been five new coal mines opened** and put on a shipping basis along this line. The coal is of excellent quality for domestic use. Charles Murphy, general manager of the Western lines, observes that there is no likelihood of a fuel famine in this particular territory, inasmuch as he has seen farmers digging coal from the surface and shoveling it into waiting wagons.

Thomas J. Brown, formerly manager of the Nova Scotia Steel & Coal works at Sydney Mines, has assumed the duties of **Deputy Minister of Works and Mines** at Halifax. He succeeds Hiram Donkin, who retired from office on Feb. 1 after serving since 1904.

WASHINGTON, D. C.

Bids are solicited for the transportation of two cargoes of Navy coal from Hampton Roads, Va., one to the Melville, (R. I.) Naval Fuel Depot and one to the Portsmouth, (N. H.) Navy Yard in vessels of American registry. To the first-named destination the cargo will consist of 4,000-6,500 gross tons, to be loaded at Hampton Roads about Feb. 28 and discharged at a guaranteed daily rate of 500 tons. The cargo to the Portsmouth Navy Yard also is to comprise 4,000-6,500 gross tons, to be loaded about March 3 and discharged at the rate of 400 tons per day.

Publications Received

Proceedings of the twenty-fifth annual meeting of the American Society for Testing Materials, held at Atlantic City, N. J., June 27-30, 1922. Vol. 22. Part I contains committee reports and new and revised tentative standards and has 1,023 pages. Part II contains technical papers and has 591 pages. Two coal papers: "A Rational Basis for Coal-Purchase Specifications," by E. B. Ricketts, and "Forms of Specifications for Purchasing Coal," by Hubb Bell, with a discussion on coal-purchase specifications, appear among the technical papers.

Twelfth Annual Report by the Director of the Bureau of Mines to the Secretary of the Interior for the fiscal year ended June 30, 1922. Pp. 33; 6x9 in.; organization chart and tables.

Proceedings of the Conference on Mine Taxation, held in conjunction with the twenty-fifth annual convention of the American Mining Congress at Cleveland, Ohio, Oct. 9-14, 1922. Pp. 174; 6x9 in.

Second Annual Report of the Federal Power Commission for the fiscal year ended June 30, 1922. Pp. 309; 6x9 in.; tables.

Fourteenth Census of the United States, taken in year 1920. Mines and Quarries, 1919. Vol. XI; 443 pp.; tables. Prepared under the supervision of Eugene F. Hartley, chief statistician for manufactures, and Frank J. Katz, special agent for mines and quarries.

An Investigation of the Properties of Chilled Iron Car Wheels, by J. M. Snodgrass and F. H. Guldner. Engineering Experiment Station, University of Illinois, Urbana, Ill. Part II; bulletin No. 134; pp. 72; 6x9 in.; illustrated. Covers the determination of the strains which may occur within a car wheel and a study of the limitations of present designs.

Chemical Engineering. Rensselaer Polytechnic Institute Bulletin, Troy, N. Y. Vol. 21; pp. 30; 5x8 in.; illustrated. Describes the course in chemistry at the Institute.

Trade Literature

American Hose and Spray Nozzles. The American Safety Lamp and Mine Supply Co., Scranton, Pa. Bulletin No. 641. Two-page folio giving sizes and prices of iron, brass and bronze nozzles.

Reading Cast Steel Valves. Reading Steel Casting Co., Inc., Bridgeport, Conn. Pp. 8; 6x9 in.; illustrated. Describes its new cast steel gate valves designed for 350 lbs. working pressure at a total temperature not exceeding 800 deg.; or 500 lbs. working pressure at a total temperature below 100 deg.

The International Combustion Engineering Corp., of 43 Broad St., New York City, has issued a 16-page catalog covering all its products, including stokers, fuel oil burners, Lopulco pulverized fuel systems and coal dryer, ash conveyors, Green pressure waterback, sealflex arch, fuel retarder, etc. The book is 8x11 in. and well illustrated.

Duraloy. Cutler Steel Co., Pittsburgh, Pa. Bulletin No. 221. A four-page description of the physical properties, composition and characteristics strength at high temperatures, machining and welding qualities of duraloy, also its oxidation and heat resistance.

Safe Tapping and Stopping. The Medart Co., St. Louis, Mo. Four-page folder describing apparatus invented for removing hazards from cupola tending.

The following catalogs have been published by the De Laval Steam Turbine Co., Trenton, N. J.: **Instruction Manual Small Single-Stage Centrifugal Pumps,** Type F. Pp. 12; 8x11 in.; illustrated. Gives complete tables and instructions for selecting pumps for different conditions, explains how to determine the proper speeds and how to select piping, valves, fittings, and driving pulley or motor. **Plants and Products.** Catalog P. Pp. 24; 4x9 in.; illustrated. Briefly describes the single- and multi-stage steam turbines, centrifugal pumps, blowers and compressors, and speed-reducing gears manufactured by this concern. **Equipment for Marquette Cement Manufacturing Co.** This is a four-page folder describing the power equipment at this plant where direct current is used.

How Hell Gate Station Handles Coal with Maine Electric Machinery. The Maine Electric Co., Portland, Me. Bulletin No. 4. Pp. 12, 9x12, illustrated. Describes the large coal-handling hoists installed at the Hell Gate Station of the United Electric Light & Power Co., said to be the largest and most rapid electric coal hoist of its kind in the United States.

Traffic News

Reduction of freight rates on coal shipped from Indiana fields to Irvington, a suburb of Indianapolis, and from Clinton, Ind., to Putnamville, Ind., is sought in exceptions to an Interstate Commerce Commission order on which evidence has just been heard before an examiner of the commission. Rates on coal shipped to Irvington are higher than the rates on coal shipped to Indianapolis. Shippers want them to be made the same.

Obituary

James D. Bastin, 83, died at Stanford, Ky., Feb. 12. He is survived by two sons who are coal producers, these being John W. Bastin, of Central City, Ky., and Sam M. Bastin, an operator in the Letcher County field.

Charles K. Wagner, one of the well known operators in the Big Sandy Field of the Northeast Kentucky district, died at the Kessler-Hatfield Hospital, Huntington, W. Va., Sunday, Feb. 11, from injuries received in an accident at the mine of the Elkhornseam Collieries Co., Elkseam, Ky., one of the mines in which he was interested. The accident, which occurred Feb. 7, was caused by a runaway car on the incline which is used to convey the men to and from their work in the mine.

Mr. Wagner became interested in this field in 1917 and had been actively engaged in its development and progress since. He and Charles W. Connor became closely affiliated in the Elkhornseam Collieries Co., of which he was secretary and treasurer. He also was president of the Excelsior Byproduct Coal Co., Shelbiana, Ky., and vice-president of the Kentucky Block Fuel Co., Jonancy, Ky., located on the Sandy Valley & Elkhorn Division of the B. & O. in Pike County. He also was interested in several operating companies in the Pocahontas Field on the N. & W. He was 42 years of age and is survived by his wife and four children.

Death has claimed **Heber J. Stowell,** oldest coal prospector in Carbon County, Utah. Mr. Stowell was born in Ogden. Among the mines he located was the Kenilworth now operated by the Independent Coal & Coke Co.

Association Activities

Northern West Virginia Operator's Association

The annual meeting of the Northern West Virginia Operators' Association held in Fairmont on Feb. 13 was attended by about 100 operators from all parts of northern West Virginia. John A. Clark, Jr., of Fairmont, was elected president of the association, succeeding A. Lisle White, who was presented with a gold watch.

Other officers elected at the annual meeting were as follows: George S. Brackett, Fairmont, executive vice-president; J. Oliver Caldwell, Fairmont, secretary; A. C. Beeson, Annabelle, treasurer; E. S. McCullough, Fairmont, labor commissioner.

The question of car rating absorbed the attention of the members of the association during a part of the meeting. The scale committee which had just completed negotiations at Baltimore for a new scale presented its report. During the course of the meeting a resolution was adopted, the sense of which was that the association would recognize and stand by its associate members. Instead of having its banquet in the evening, the association staged that function at one o'clock in the afternoon at the Fairmont Hotel. There were splendid addresses by Director Smith of the U. S. Geological Survey and Attorney Wilbur LaRoe, of Washington, D. C.

Upper Potomac Coal Association

Members of the Upper Potomac Coal Association met in annual session at Cumberland, Md., Feb. 10, the attendance representing a large portion of the tonnage of the Upper Potomac and Georges Creek fields. Keen interest was manifested in the discussion of problems affecting the coal industry. The following directors were elected: W. F. Ambrose, Cumberland; J. G. Emmons, Philadelphia; R. A. Smith of Blaine, W. Va.; S. D. Brady, Fairmont; A. S. Brady, Elkins; Marsh Dean, Elk Garden; T. M. Dodson, Bethlehem, Pa.; Douglas Gorman, Baltimore, Md., and Carroll Pattison, Bloomington, Md.

At the banquet which followed the annual meeting addresses were delivered by Senator Sutherland, of West Virginia; Judge A. A. Daub, of Cumberland, and B. F. Biser, of Cumberland. All the speakers joined in urging business men to bring about industrial rest. In his address Senator Sutherland said, among other things: "If a failure of fuel production should persist through unfortunate misunderstanding or clash of interests, the specter of government operation or ownership will again arise. It is quite possible that if the patience of the public becomes wearied because of an uncertainty of fuel supplies, drastic and unwholesome legislation may be expected."

Monongahela Coal Association

Work was planned for the year at the meeting of the Monongahela Coal Association held in Morgantown during the second week in February, when consideration was given to a number of questions of particular interest to members of the association. John H. Jones, of Pittsburgh, elected president at the annual meeting, presided and announced the appointment of committees. Following the meeting of the membership of the association, the board of directors held a session.

Coming Meetings

The Rocky Mountain Coal Mining Institute will hold its winter meeting Feb. 26-28 in Denver, Colo. Secretary, Benedict Shubart, Boston Building, Denver, Colo.

American Institute of Mining and Metallurgical Engineers will hold its annual meeting Feb. 19-22, 1923, at the Engineering Societies Building, New York City. Secretary, F. F. Sharpless, New York City.

International Chamber of Commerce will hold its second general meeting in Rome, Italy, March 19-26.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

Northwestern Pennsylvania Coal Operators' Association will hold its annual meeting March 6 at the William Penn Hotel, Pittsburgh, Pa. Secretary, T. F. Diefenderfer, Butler, Pa.

Canadian Institute of Mining and Metallurgy's annual meeting will be held March 7, 8 and 9 at the Mount Royal Hotel, Montreal, Quebec, Canada. Secretary, George C. Mackenzie, Montreal, Quebec, Canada.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., Dec. 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

Indiana Bituminous Coal Operators' Association will hold its annual meeting March 14 at Terre Haute, Ind. Secretary, P. H. Penna, Terre Haute, Ind.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

Southern Appalachian Coal Operators' Association will hold its annual meeting Feb. 23 at Knoxville, Tenn. Secretary, R. E. Howe, Knoxville, Tenn.

The executive board of the **Coal Mining Institute of America** will meet in Pittsburgh, Pa., Saturday, March 3.

The Gas and Fuel Section of the American Chemical Society is arranging a second sectional meeting at the New Haven meeting of the American Chemical Society during the first week in April. The section program will consist of papers on gas and fuel chemistry and a symposium on motor fuels, held jointly with the petroleum division.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

The Tri-State Coal Stripping Association will hold its annaul meeting March 1 at Pittsburgh, Pa. Secretary, Geo. A. Blackford, Wheeling, West Va.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, THURSDAY, MARCH 1, 1923 Number 9

Classification of Coal

NOTHING is more certain than that coal is a complex substance made of many forms of vegetal matter mixed with various kinds of ash-forming material. We cannot expect the "pure coal matter" from many beds or from the various strata of any one bed to be of the same specific gravity. Heavy coal may consist of heavy vegetal material and little ash. Light coal may be composed of light coal matter and more ash or an ash of low specific gravity, for the "ash" itself may vary in density. Coal resins, as witness those at Coalmont, B. C., may have a density of 1.03, whereas coaly matter is generally of much greater weight.

In view of these facts it might seem remarkable that coal can so readily in most cases be classified by gravimetric methods. Its weight usually is an indication of its degree of purity, but it may not always be so, and the assumption that it is so is not quite safe, as has been shown on Vancouver Island. Where classification by specific gravity of the seam or seams coming to a washery is not parallel to a classification by ash content, separation of good coal from bad cannot be left to the arbitration of gravity classifiers no matter how well they perform their tasks. They might be perfect in achieving what they attempt to do but fail utterly to do what they should do, namely, separate clean from dirty coal.

Most of our classifiers which operate on other physical qualities than specific gravity do their work somewhat imperfectly. Some rely on the rounded form of coal and the bedded form of slate. One, the flotation process, the possibilities of which are intriguing, depends on the surface tension of a mineral body like coal as compared with that of gangue like slate or sandstone. Here also are assumptions. To begin with, the pyrite which is found with coal is a mineral and disposed to float on a froth. However, it is heavier than coal and perhaps for other reasons is not as ready to float as is that mineral. At least, flotation experts tell us that coal floats more readily than pyrite. If so, this is well indeed. The industry will be pleased and surprised to see it sink, in some percentage at least, with the gangue.

Still we do not know that the selective action of a froth in contact with coal increases regularly with the purity of the mineral. Is the attraction of all pure coal substance equal and, even if it is, may not some ashy materials decrease that selective action more than others? To determine if this is so is perhaps a hopeless task at this stage of the art. The only way is to test coals to see which gives the best result. It is important, however, to remember that all classification proceeds on the doubtful premise that by grading the coal according to certain physical qualities we are classifying it according to its calorific value. In some cases it may be true, or true enough for practical purposes; in others it may be far from the truth. Let us in any event proceed with an open mind lest the operation be successful yet the patient die.

It must be remembered also that the flotation process depends on the most superficial of externals and in any particle of variable material external impurity will have more effect than impurity that is internal. Thus another variable is introduced, one that in gravimetric methods does not exist.

Publicity for Coal

PEOPLE like to read that which pleases them. They buy the newspaper that says the things they like to hear. They read the books that tell the story in the way they think it should be told. It is confirmation of their worst fears, their strongest likes and dislikes, that the average reader seeks. The public believes many strange and fearful things about coal—that the coal men are in combination to rob them, that dishonest and iniquitous practices prevail throughout the trade, that so many things are wrong with the whole business that "something" should be done to fix it up, that "the government should take a hand" in straightening out a snarl so complicated.

It is interesting to note how the newspapers help this warped understanding to grow. Some weeks ago there was much in the public prints to the effect that a strike in the soft-coal fields was imminent. The miners and operators met in New York to talk over the matter of an agreement to continue work after the present contract expired. The papers carried front-page headlines about the meeting that was to be and during its progress held the public in suspense as to its fearful outcome. Then when all was amicably settled and the strike cloud was dispelled for some fifteen months to come, did the public learn in the same front-page headlines that a great thing had been accomplished, that the thing which appeared doubtful was in fact to be, that there would be no strike? By no means, for the news that an agreement had been reached was buried well inside the sheets with inconspicuous headlines. Small wonder then that some do not know that the mines are working. Four months after resumption of mining, on Dec. 29, 1922, Henry W. Rose, general manager of the Republican National News Service, wrote to the chairman of the U. S. Coal Commission, saying: "The mines should reopen, and the men should go back to work."

It is a poor coal famine that does not freeze someone, so the papers carried front-page headlines on Feb. 19 telling the world that an aged woman, lacking coal, had perished from cold in northern New York. Later editions advised, with notable inconspicuousness, that she really had plenty of coal on the premises, but the correction will never overtake the headlined error. One victim at least will popularly be charged to the coal shortage of this winter.

Last week the United Mine Workers broadcasted a statement well calculated to inflame a near coalless

public. With all the care in the use of facts that marks the prospectus of a bogus oil promotion, this statement concludes that "the present monopoly organization of anthracite, through overcharges in each branch of the business, adds at least $3.61 per ton, which is immediately discoverable, to the present price the consumer pays, and much more which cannot be exactly estimated." Such an opportunity for headlines could not be resisted by newspapers, as the authors of the statement well knew and calculated. The reply of the anthracite operators, calling attention to the fact that the U. S. Coal Commission is now engaged in an investigation designed to settle that important and controversial point, and suggesting that such assertions from the miners are but attempts to prejudge the case and mislead the public, was fortunate in getting publicity here and there as inside filler.

Now this is not mere caviling at the press. By all the modern tenets news is news when it is startling, novel, sensational. If the coal operators rob the people, that is news, but if they do not that is not news. If the miners go on strike, that is news, but if they do not strike, such is not news. Not all readers care for sensation; some desire plain facts. Thus we find different publications catering to a large number of different tastes.

Men in the coal trade have as wide a variety in taste for "news" as any other section of the public. Some read only that which pleases them, and, caring for warped news and peddled gossip, they have created a market for what, for want of a better designation, may be called coal-trade scandal. Such a one, either fearing the light of day on the facts of his business or considering lightly the task of the Coal Commission, indulges himself in a printed sheet advising and encouraging the belief that the best and surest way to ward off the consequences of national public dissatisfaction with the coal men is to tell the public to go to hell, that questionnaires are violations of constitutional rights of private business, that everyone in Washington save a very select few is secretly plotting to take over the coal and all other business.

On the one hand, headlining news when it makes coal out the scapegoat; on the other hand, gossip, some quite original, hawked for a consideration, attempting to make the public the scapegoat. There is mightly little distinction in the doing or the believing between the two.

How Many Cars Should a Mine Get?

ALTHOUGH tastes may and do differ as to method, the purpose of all plans for coal-car distribution is to furnish equitable division of the means of getting coal to market. It really matters little whether the rating by which the cars are apportioned is inflated, provided the inflation as between the mines on a given railroad is uniform, for the figure purporting to represent the capacity to load is but a ratio, an abstract figure. Simple as it may appear to be to determine such ratios and to apply them in practice, the difficulties are great.

Prior to the war every road had its own method, and it is to revert to this condition after five years' of trial of uniform rules, known as CS31, that present effort is being directed.

There is a plain need in many a coal-mining field for a correction in the number of cars each mine may order in a day. Abuses under CS31 have made rank overrating altogether too easy. Everybody admits it. Fervently it is to be hoped that the new methods of rating mines about to be adopted in some of the Eastern fields will have a salutary effect for the benefit of the whole industry. But the fact that both carriers and operators in those fields may agree upon the fairness and success of any method for their own use does not prove that the same method should work everywhere in the United States. Where the grip of unionism is as strong as it is in Illinois and Indiana and where slope and drift mines are so few, the limited time of each working day and the limited storage capacity for loaded pit cars at each operation put the unionized shaft mines in a class requiring separate treatment.

The Illinois Central and Chicago, Burlington & Quincy railroads wish to create a railroad board for each line to fix arbitrarily the car rating of each mine, after considering various factors, following after the Chesapeake & Ohio and the Norfolk & Western plans. They cannot be blamed for wishing to take into their own hands the vexing question. Too many wiles have been practiced. Something is the matter when the mines of a single railroad system are rated at 6,400 cars a day, based on the mine operators' reports, and when 4,400 cars stands as the maximum ever ordered in any one day and 2,500 cars is the average loaded out! Something certainly needs correcting in a car-rating system when it is freely admitted by operators, as it was recently in a Chicago conference of mine men and railroaders, that the mine reports of hours worked are deliberately falsified and that double sets of records are sometimes kept! Who can blame the railroads for growing weary of it?

Under CS31, now in effect, mine ratings for each month are determined upon the number of hours worked and cars loaded under the tipple during the preceding month. There is no better and fairer basis providing the data are correct. The railroads have taken the mining companies' reports on the hours worked. They say they could do nothing else. It would have cost too much. And in cases where they have declined to accept a mine report and have reduced a mine's car rating, they have drawn harrassing and expensive lawsuits. It is easy to say that CS31 is adequate and requires only that the railroads police the reports to make it equitable and successful. It must be admitted that policing has its difficulties. The policing should not be required of the railroads alone. Mine operators themselves should assume a large responsibility and, having done their part, they should suffer in their car rating no stint from the carriers or any other source.

The compromise plan suggested by Illinois and Indiana that the preceding month's production basis be retained and that a railroad board examine any mine suspected of falsifying reports of time worked has its possibilities. Its penalty clause, empowering the board to run a three-day test in case of disagreement with the mine owner and to dock him in subsequent car supply to the extent to which he benefited by padding his report, is a real weapon in the railroads' hands, poor a device as is such a test would be. The suggestion should be seriously considered. It certainly would cost the railroads something to maintain such a board, but if they intend, under their own proposed plan, to make an adequate study of each mine's condition in order to arrive at a proper rating, then the compromise plan would be no more expensive than their own; it probably would be less costly.

Betsy Layne Mine Presents Unusual and Suggestive Methods of Construction and Operation

Dump Houses Separate from Tipple Structure—Belt Conveyors to Commercial Screens—Preliminary Screening Protects Belt by Putting Slack Under Lump—Well-Equipped Isolated Power Plant—Roof Gunited and Stoppings of Concrete

By F. R. Morris*
Betsy Layne, Ky.

ONE of the most recent of the large modernly equipped coal plants to be opened up in the eastern Kentucky field is the Betsy Layne mine of the Pike Floyd Coal Co., a subsidiary of the Pittsburgh Coal Co. The mine lies on a two-mile spur from the tracks of the Chesapeake & Ohio R.R., in Floyd County, seven miles northwest of Pikeville, Ky. In few places in this field is construction of so permanent a character or the mechanical detail carried to such a degree of refinement.

This property, comprising approximately 2,000 acres, lies on the east side of the Big Sandy River. Of this area, 1,400 acres is underlaid by two seams of coal of commercial value. These are known as the "Elkhorn" beds, no satisfactory correlation having been made between these measures and the coals of West Virginia and of other bituminous fields. In many respects, nevertheless, they correspond to the Kanawha River series.

These two measures are separated by a short interval, 40 to 70 ft. thick. They lie not far from water level. Consequently the coal area is not cut up by ravines into narrow fingers but is of such a shape that a regular system of mining can be adopted. The hills in this locality are broad and gently rounded, which accounts for the occurrence of a large unbroken tract of coal in a field where most of the bodies of coal are of such a shape that a simple mine layout is impossible.

The upper, or No. 3, seam, which is the one now being mined, has an average thickness of 5½ ft., as determined by careful drilling and prospecting made when the property was acquired. It is a high-volatile coal similar to those from the No. 2 Gas and Pond Creek seams of West Virginia, though lower in sulphur content and suitable for byproduct coking. The coal is fairly hard and stands preparation well.

The presence of two partings in the coal, the thickness of each averaging 3 in., makes mining difficult; these partings occur 15 in. and 36 in. respectively from the bottom. They are of hard blue shale and, though not difficult to remove from the coal, must be broken by a charge of explosive. This greatly increases the percentage of fine coal obtained. In some cases the top is a hard, evenly bedded shale; in others, and especially near the outcrop, it is soft and laminated with coal, which is unevenly bedded and filled with fossils.

The location of the property on the east side of the river made it necessary to construct a bridge and build

FIG. 1—RAILROAD BRIDGE CONSTRUCTED TO MINE

Our railroad work has passed the stage of wood. In the most remote sections of the country, railroad bridges, even when made for temporary use, are built on stone or concrete foundations and constructed of steel. But reasons seem always ready at hand for justifying the use of wood in mine structures. Is it really reason or merely habit?

*Resident Engineer, Pike Floyd Coal Co.

NOTE—The headpiece of this article illustrates the Betsy Layne tipple of the Pike Floyd Coal Co., Betsy Layne, Ky. No cars pass over any part of the trestle structure, nor is the trestle subjected to dumping strains. Note how firmly planted on the hillside is the dumphouse on the right and also how satisfactorily the belt conveyors lift the coal from a point below true tipple height to the elevation required. This plant is planned to dump 5,000 tons in a day. Note on the left the housing of the flight conveyor. This conveyor carries coal to the boiler room.

two miles of standard-gage road to connect with the Chesapeake & Ohio R.R., which is the outlet for this district. Because the railroads constantly tend to increase the size and weight of their coal-handling equipment, this bridge has been of heavier construction than present requirements would justify. It is composed of seven plate-girder spans with one 200-ft. through-truss span over the main channel.

The capacity of the yards is greater than is customary, as space is provided for 100 cars above and for an equal number below the tipple. Two systems of turnouts above the tipple permit the cars to be switched to any track; thus the equipment received can be sorted out to suit the day's loading and any particular size can be loaded into such equipment as the order specifies. In order to facilitate the movement of cars all loading tracks are constructed on a grade of not less than 1.14 per cent. Directly under the tipple the grade is increased to 1.75 per cent.

At the point where the coal lies at tipple height the valley has widened out to 380 ft. and divides the property approximately into two halves. These conditions favored the construction of one tipple which would handle the output of two mines, one on the north side and one on the south side of this valley. The plan thus offered was adopted and a twin tipple erected with a capacity to handle 300 tons per hour from each side, or a total of 5,000 tons per day. For an elevation of this two-unit tipple see Fig. 2.

As much of the coal goes to the domestic market, one of the major points considered in the design of this tipple was the elimination of all such equipment as would break the coal unnecessarily. In order to clarify my description I shall describe only one dumphouse and conveyor gallery, as the others on the opposite side of the valley are duplications of these. The wooden superstructure of the dumphouse rests on 16-in. basement walls of concrete in which are included a concrete receiving bin underneath the dumping floor. This heavy concrete foundation absorbs the shock of dumping so that it is not transmitted to the tipple structure.

By means of a crossover dump the coal is discharged into an 8-ton bin and is then fed by an apron feeder over a 1½-in. bar screen to a rubber-belt conveyor which carries it to the shaker screens on the tipple proper. The bar screen under the feeder separates the slack from the lump so that the former drops directly on an inclined pan discharging to the belt conveyor.

The coal which passes over the screen is discharged onto a rubber-belt picking table. Here two men are

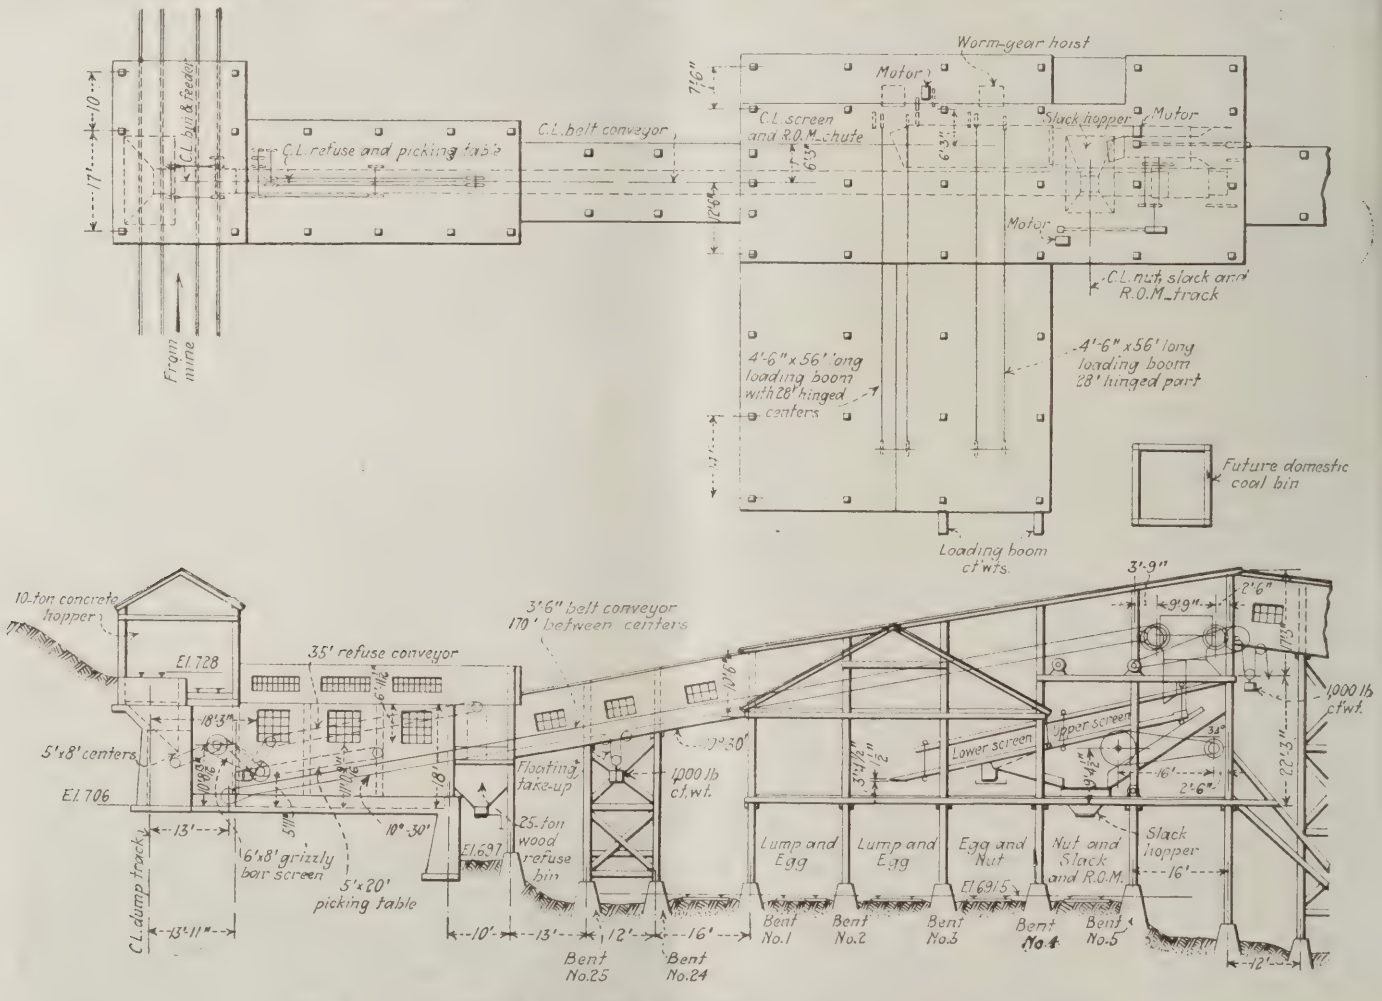

FIG. 2—PLAN AND ELEVATION OF A TWO-UNIT COAL TIPPLE AT THE PIKE FLOYD COAL CO.'S MINE, BETSY LAYNE, KY.

The tipple consists of the part over the railroad tracks and of the buildings at either end in which the preliminary dumping and cleaning is performed and the belts are loaded with the coal. These latter are almost exact duplicates, so only one is shown here. The coal lies almost at full tipple height in the hills on both sides of the valley where the dumping point has been established and the output from the mines is loaded into the cars on a single five-track yard. The dump cars do not go on to the tipple but are discharged by crossover dumps in dumphouses on either side. The coal falls into an 8-ton bin and is fed by an apron feeder over a bar screen. Whatever goes through passes to a long rubber-belt conveyor. The larger material goes to a rubber-belt picking table and receives at least a preliminary cleaning. Reaching the end of the table it is discharged onto the long rubber belt previously mentioned and passes to the part of the tipple over the railroad. The tipple is high, the comb of the roof being about 63 ft. above the top of the foundation and about 55½ ft. above the elevation of the track.

employed to clean the coal thoroughly before it reaches the center of the tipple, in the event that it is to be loaded as run-of-mine, or to give it a preliminary cleaning before it reaches the screens and picking tables above the railroad tracks in case sized coal is to be loaded. Above the picking table in the dumphouse is a scraper conveyor which discharges the refuse into a 25-ton wooden bin under which a mine track has been laid. Mine cars are spotted under the bin, and when loaded are hauled to a horn dump on the slate pile.

The conveyors which carry the coal from the dumphouse to the tipple proper are made up of six-ply rubber-composition belting 42 in. wide. When delivering their full capacity of 300 tons per hour each they run at a speed of 225 ft. per minute. The power cost of driving these conveyors is low. A 30-hp. motor drives each

FIG. 3—FEED-WATER HEATER AND STIRLING BOILERS

The Betsy Layne boiler house is equipped with two 270-hp. boilers, operating under a pressure of 300 lb. per square inch. The water for these boilers comes from the Big Sandy River, which is four-fifths of a mile away. It is delivered to the power plant by centrifugal pumps located in a submerged pumphouse.

belt. They are about 200 ft. long between centers and operate on a 7-deg. slope against the load. They require no attention other than the oiling of the idlers and pulleys. This is done by a man who looks after the operation of all tipple machinery and is responsible for its proper performance.

Leaving the belt the coal goes into a pocket, from which it may be diverted by a system of flygates to either of the screening rigs or to the run-of-mine chute, which leads directly to the railroad car. The fines are diverted and run back to be loaded into railroad cars through the run-of-mine chute. The egg and lump sizes go from the screens to loading booms having a 27-ft. table on the tipple deck for any further cleaning that is necessary. The distribution of the sizes and the combinations that may be obtained are best indicated by referring to Fig. 2.

FIG. 4—REPAIR HOUSE IS BUILT OF STEEL

Too many of the repair shops around mines are constructed of wood with a few small inadequate window lights. The form of building here illustrated is substantial, inexpensive and fireproof and adapts itself readily to adequate lighting. The main building houses the carpenter and blacksmith shops and the annex the electrical-repair shop.

The method by which power is distributed and the motors controlled in this tipple is of special interest. The main feeder leading from the power house comes to a panel at a central location. From this board independent circuits are carried to each motor, and switches and fuses for these circuits are mounted on the main switchboard. With such an installation it is unnecessary to stop the entire tipple should trouble occur on any one circuit. All motors are operated with automatic starters having remote control and may be started or stopped from the trimmers' platform. A system of pushbutton alarm signals also keeps the men on the trimmers' platform in touch with the dumphouse. This system provides a flexible control and eliminates the employment of men who otherwise would be required to look after the operation of motors.

Because the tipple is constructed of wood some adequate means of fire protection is imperative. The problem is solved by placing a 4-in. main up the center of the tipple from the boiler-feed pumps. From this main 2½-in. branch lines are taken to hose connections so distributed that any point of the structure can be reached. The tipple was erected and furnished by the Webster Mfg. Co., of Chicago, Ill.

Two 300-kw. units driven by Ball and Skinner engines generate a 275-volt direct current which is used throughout the operation for light and power. The generators were designed for 575 volts, but the armatures were

FIG. 5—UNUSUALLY WELL-LIGHTED REPAIR SHOP

Quite in contrast with the dingy workshop at the average coal mine but wholly in keeping with modern factory-building practice in the matter of lighting is the repair shop of the Betsy Layne mine.

FIG. 6—BATHHOUSE WITH SHOWERS

This building is supplied with heated air. The clothes are not suspended from the roof but are kept in lockers. The floor is of concrete as also is the wash trough. In this building are ten showers and thirty-two wash faucets.

rewound for 275 volts and the fields reconnected in multiple.

The original intention was to equip this plant with turbine units, and the boiler equipment was put in with this idea in mind. The installation is provided with two Stirling-type boilers each of 270 hp. The boiler pressure is 300 lb. per square inch. The feed-water piping is so arranged that either of the two pumps which are installed can supply hot or cold water to the fire line on the tipple.

Feed water is obtained from the Big Sandy River, which lies at a distance of 4,200 ft. It is pumped by two De Laval double-stage centrifugal pumps located in a concrete dry well at the river bank. These deliver water to a 60,000-gallon steel tank at the power house which is elevated on steel legs 40 ft. above ground level. The pumps each have a capacity of 125 gallons per minute, work against a discharge head of approximately 145 ft. and are driven by 20-hp. motors equipped with remote control starters which can be operated from a switch panel in the power house.

Pump Room Set Below Level of Water Supply

In order to have the pumps properly primed at all times they are set below the level of the water in the river. Thus installed the well would be flooded should the pumps leak. To guard against this contingency a float switch is installed in a small sump within the well. Then if the water rises to a certain height the switch closes an independent circuit which passes through a lamp on the switchboard in the power house. When by reason of the current the lamp is ignited the engineer is warned and the pump can be shut down and repaired before serious damage is done.

The coal supplied to the power house is dropped from the tipple by means of a chute coming from under the 1½-in. screen. It is then transported by a small flight-conveyor to two 25-ton cylindrical hoppers in the boiler room. The boilers are fired by hand.

The switchboard in the generator room has eleven separate panels which give the following independent circuits: trolley, machine-feeder, fan, tipple, river pumps, street lights and house lights. Each panel is equipped with ammeters and automatic circuit breakers; the generator panels also have voltmeters and an under-voltage release.

Though the first cost of such a system of distribution is high, much is saved by the early detection and localizing of short-circuits, especially when the plant is of the size of that herein described. The system is further carried out in the mine by sectionalizing all branch feed-

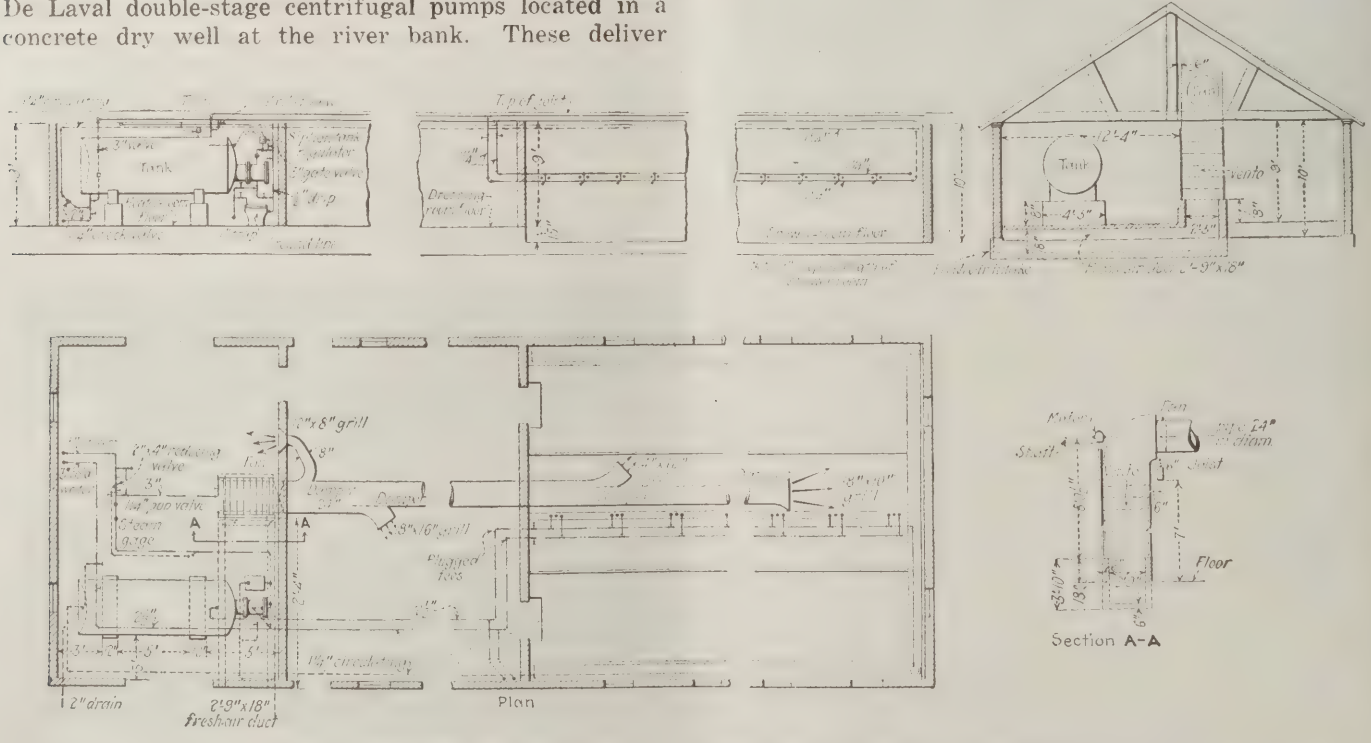

FIG. 7—SYSTEM OF HEATING OF BATHHOUSE AT BETSY LAYNE, KY.

An air intake under the floor measuring 33 x 18 in. encircles coils filled with exhaust steam from the power house. This heats the ventilating current. The warm air is then forced into an overhead air duct which discharges into the locker or shower rooms. Thus the bathhouse is under a pressure of air, and when the doors are opened the air tends to escape, whereas in most bathhouses the air enters in copious measure whenever the doors are opened, that being inevitable where the air in the bathroom is at a lower pressure than that outside. No cry is more frequent around a bathhouse than "keep that door closed."

ers and trolley circuits. In carrying direct current at this voltage over the distance required at this operation the system of distribution just mentioned is aided by the proper suspension of lines and efficient bonding, which aid in insuring continuity of service. Particular attention is paid to return lines, negative lines of 750,000 c.m. cross section being carried to the generators from a point in the mine track not far distant from the drift mouth.

The building which houses the machine, electrical-repair, carpenter and blacksmith shops is shown in Fig. 4. It is a standard Truscon steel-and-glass structure of saw-tooth design. The merits of this type of building are its low first cost and the short time required for erection; this particular building was completed in less than two weeks. It is fireproof and the large area of sash assures an abundance of light. Because of the isolated location of this plant the shop is prepared to take care of all electrical and mechanical repairs. The machinery is driven by one electrically-driven line shaft and all belts are protected by wooden guards.

The bathhouse is a frame building which is heated by a Vento heater utilizing the exhaust steam from the power house. As indicated in Fig. 7, an air intake under the floor encircles the steam coils, which thereby heat the air by which the building is ventilated. The dry warm air is then drawn into an overhead air duct which discharges into the locker and shower rooms.

Fig. 8 is a map of the territory surrounding the mine plant on which are shown the buildings and the mine

FIG. 8—MINING PLAN AND SURFACE LAYOUT

Not all the houses are shown, two small groups being at the head of Tuscaroare branch, one up each fork. The long easy curves of 200-ft. radius used at this mine for underground roadways are much in evidence. Unfortunately, the fossily roof is too weak to hold up over the places in the headings where such long curves fork and in future the curves in the outgoing tracks will be made shorter, evidences of that intention being seen in the more remote workings of the mine.

FIG. 9—WELL TRIMMED TWELVE-FOOT ROADWAY WITH HALF-INCH GUNITE COATING ON ROOF

Gunite not only covers the roof but is carried down the coal rib as shown. Of all roofs few are more trying then one filled with coal and especially fossil ferns. This roof is of that character. The cemented roof not only does not fall but keeps up the trolley wire. When the number of fires resulting from fallen trolley and other electric wires is considered the advantage of such guniting becomes the more evident. A little work of this kind may be looked upon as insurance against electric fires. It also reduces the hazard consequent on the use of timber for mine supports and serves to make the illumination of the roadways more effective.

layout. The tentative system of development may be changed at a later date if conditions warrant a change. As already stated, the roof of these mines is a blue shale, full of fossils and laminated with coal. This top is readily slacked by the air current, and for this reason the practice of driving double-track rooms, 30 ft. in width, was abandoned in favor of the 25-ft. single-track room shown in the illustration.

This top also prohibited driving curves of 200-ft. radius at the mouth of each butt, which was the practice first adopted. With a curve of this length the unsupported span was too wide at the point where the entries diverge, and the increased efficiency in the haulage was not sufficient to justify the expenditure for elaborate steel timbering.

To overcome these difficulties with the mine roof a cement gun was installed, and gunite is used on all main haulageways and entries wherever they are not subject to excessive weight such as will bring down the roof. On some of the entries the gunite has been in place more than four months and has so far checked cutting and weathering actions. In this case it is cheaper in first cost than timber and it saves maintenance charges by preventing the scaling and spawling of rock and the expense entailed in cleaning up the roadways thus encumbered. Furthermore, the trolley wire no longer comes down. The coating applied is about $\frac{1}{2}$ in. thick and costs approximately 80c. per linear foot in a 12-ft. entry. The type of stopping used on all permanent entries is constructed of 8x8x20 in. concrete blocks laid up in cement mortar, as shown in Fig. 10. The sides are hitched into the ribs and plastered. Gunite is used to seal the top and sides. This coating is extended if necessary from 12 to 18 in. each way from the edges of the stopping. This eliminates the possibility of small leaks.

Concrete Stopping Blocks Made at Mine

The concrete blocks are made at the plant by day laborers who use a machine designed to facilitate their construction, and thus far the only aggregate used has been the fine coal recovered from the stockpiles which accumulated when the mines were first opened. These blocks were given thorough tests to determine whether the coal aggregate would lower their fire-resistance. It was discovered as a result of these experiments that the

FIG. 10—CEMENT-BLOCK STOPPING WITH GUNITE EDGES
Though the Betsy Layne mine is just starting, it is not handicapped by poor stoppings which will leak and soon rot and have to be replaced by something tighter and more permanent. The weak point in most stoppings is around the edges. Even a cement stopping may fail here. With gunite, not only are the cracks between the stopping and the roof and sides calked but the natural or developed cracks through the roof and the pillars can be entirely shut off if the gunite is carried far enough.

blocks in which coal had been used in place of gravel would resist fire as readily as if gravel were used.

Each mine is ventilated by a 3x8-ft. centrifugal fan which is rated at 120,000 cu.ft. against a 3-in. water gage. It is driven by a 35-hp. motor equipped with a remote-control starter and a field rheostat which is used at present to reduce the speed into keeping with the limited area of the workings. This rheostat is mounted on a panel which also has an automatic circuit breaker and an undervoltage release. The fan is equipped with explosion doors and is housed in a brick and concrete building.

The coal is undercut by shortwall machines and the haulage equipment consists of 4-ton cable-reel gathering locomotives and 13-ton haulage locomotives. The mine cars are of 2½-ton capacity and are equipped with roller bearings. All main haulroads are laid with 40-lb. and the butt entries and rooms with 20-lb. steel. No. 5 turnouts with cast frogs are used for main-haulage roads and No. 3 turnouts have been adopted as standard for rooms and secondary haulageways.

At this time development has not progressed far enough to connect the North and South mines underground. In order to get machinery and equipment from the South mine for repairs and to permit the refuse from both mines to be handled over one dump, the outside tramroads on each side are connected by a steel

FIG. 11—MINE SHOWING STEEL CONNECTING TRESTLE
As the North and South mines are not yet connected and as any connection will be quite roundabout a steel trestle has been built connecting the mines, making it possible to take cars, locomotives, mining machines and other equipment to the repair shop and to discharge all refuse over one dump.

trestle which crosses over the railroad tracks. This trestle is designed for a load of 50,000 lb. and carries a walkway in addition to the track. The bents of the trestle are constructed of 12-in. I-beams set on a batter. They are spaced on 20-ft. centers though there is one span of 30 ft. The bents are tied together with angle-irons. The deck is composed of 18-in. I-beams with diagonal bracing and struts. The trestle floor is supported over the 30-ft. interval by 20-in. I-beams.

The management aimed to have the mechanical and electrical equipment complete in every detail and to install this quipment in such a manner that the expense for upkeep and repairs would be a minimum. As far as is possible under the conditions to be met the surface plant has been concentrated so as to simplify the problem of supervision and to eliminate all needless expense in the hauling of coal and the handling of supplies. By careful development and a concentration of the mine workings the mine equipment can be made to operate with maximum efficiency, thereby furnishing a large tonnage at a low cost.

Manufactured Fuel Valued at $3,178,000 Produced in 1921 by 14 Plants

THE value of products of establishments engaged primarily in the manufacture of fuel, according to reports made to the Bureau of the Census, the Department of Commerce announces, amounted to $3,178,000 in 1921, as compared with $1,974,000 in 1919, and $863,000 in 1914, an increase of 61 per cent from 1919 to 1921, and of 268.2 per cent for the seven-year period 1914 to 1921. The industry includes establishments engaged in the manufacture of briquets from bituminous coal and anthracite dust mixed with tar and pitch as a binder; a composition of charcoal, pitch, tar and soda; also fuels made of crude oil and sawdust, etc. Of the 14 establishments reporting in 1921, 2 each were located in Indiana, New York, Pennsylvania, Virginia and Wisconsin, and 1 each in California, Missouri, New Jersey and Washington.

In January, the month of maximum employment, 440 wage earners were reported, and in April, the month of minimum employment, 284, the minimum representing 64.5 per cent of the maximum. The average number employed during 1921 was 371 as compared with 171 in 1919. The statistics for 1921, 1919 and 1914 are summarized in the following statement; the figures for 1921 are preliminary and subject to such change and correction as may be found necessary from a further examination of the original reports:

	1921	1919	1914
Number of establishments	14	11	14
Persons engaged	464	228	174
Proprietors and firm members	3	.....	4
Salaried employees	90	57	29
Wage earners (average number)	371	171	141

IN CO-OPERATION WITH the Combustion Engineering Corporation, tests are to be conducted by the U. S. Bureau of Mines at the River Rouge plant of the Ford Motor Co. on the largest boilers so far constructed. These tests will supplement the knowledge gained in previous tests on differently designed boilers when heated by powdered coal.

Blowouts in Belgian Coal Seams and the Way in Which These and Like Phenomena May Be Explained

Seams Which Sing and "Walk"—Morin's Theory of Expansion of Coal—Preliminary Warnings — Bumps, Vibrations and Breaking of Timbers — First and Second Winds—Grappe Blowout and Explosion—Ruelle's Polymerization Theory

By F. C. Cornet.*
New York City

THERE may be much that is not novel in the following article, but it contains also a few facts that are not as generally known as they should be. I mean especially L. Morin's theory of seam expansion and H. Ruelle's hypothesis of methane polymerization.

Morin is a Frenchman; Ruelle is a Belgian. The former is chief engineer for the Lievin Coal Mining Co., of France; the latter occupies the same position with the Houssu division of the Ressaix Coal Co., of Belgium. In those countries, where only duly qualified mining engineers are employed in any position of responsibility in or around mines, the chief engineer always is the operating manager, having full charge of everything except the sales department.

With both Morin and Ruelle blowouts are a matter of hourly concern, their respective mines experiencing in the course of the year scores of such manifestations. The precautions which rendered the mining of other seams that were subject to blowouts comparatively safe failed so completely to protect the miners in the Houssu mines of the Ressaix Coal Co. that for many years these workings could not be operated. As a result of Morin's investigations new safety measures have been put in force which make the working of these abandoned seams reasonably safe.

It is due to such men as Ruelle and Morin, who have spent their whole business life in daily contact with the operation of seams of this kind, studying their frequent manifestations under their different aspects and applying continuously new preventive measures based on knowledge thus gained day by day, that it is now possible to mine, with profit and little loss of life, coal beds that only a few years ago were shunned by even the most enterprising and daring of coal-mining men.

Belgians Drive Tunnels from Hoisting Shaft

In Belgium, where the coal measures pitch at all kinds of angles (see illustration), the coal seams are entered through tunnels driven from the hoisting shaft. These tunnels are excavated across the strata on an upgrade such as will insure drainage and facilitate the haulage of loaded cars. The Belgian terms such a tunnel a *bouveau*.

We will suppose that a *bouveau* is being driven through the measures to top beds which are subject to blowouts, these beds being found only in the deeper measures at the base of the coal-bearing formation. On such a *bouveau* reaching a seam, the gas in the latter—that is, the methane it contains—begins to issue from the coal with a rustling noise called the "song of the seam" (*le chant de la veine*). As the *bouveau* drives through the seam, the latter, becoming freer and freer, immediately starts to expand into the empty space thus afforded.

The coal thereby loses some of its cohesion and lustrous appearance, the movement and the release of pressure modifying the condition of the coal from a depth varying from less than an inch to possibly 2 ft., depending on whether the seam is hard or soft, but without any regard to the quantity of gas per cubic foot of coal that the seam may contain. Two seams may be equally gaseous, but while the harder one will perhaps be altered to a depth of less than an inch, the softer one will soften and discolor for a depth of perhaps 2 ft. all around the opening which the *bouveau* makes in the seam. But no matter how deeply or how shallowly the coal may be affected, if the softened coal be dug out, the alteration in both color and cohesion will progress further into the solid.

Soon after the *bouveau* reaches the far side of the seam the latter ceases to expand. The cessation of expansion always coincides with a marked decrease in the emission of gas. The seam does not cease to emit gas, however, until some time thereafter. The period of time during which the emission continues at the abated rate is short where the seam is hard and difficult to mine. It is much longer when the seam is soft and is dug with ease, this, despite the fact that both seams may be equally gaseous—that is, contain the same amount of gas per cubic foot of coal.

Expansion Continues as Long as Face Is Worked

In regular mining operations, the same results are obtained. The only difference is that they take place on a much larger scale, in proportion to the development of the workings and the rate at which the faces are driven. It may be said that the expansion of the seam never ceases so long as the faces continue to be worked. The expansion of the coal bed when intersected by a *bouveau* is almost inappreciable in linear extent, but it becomes plainly visible in regular workings, where whole longwall faces may sometimes be found in the morning to have advanced—that is, expanded—several inches over night. On noticing this when they come to work in the morning, the men say: "the seam has walked" (*la veine a marché*).

When workings for any reason are stopped for a sufficient length of time, there is at first no marked decrease of gas emission, and there is none until the expansion has run its course. In the case of extensive workings this may take weeks if the seam is a soft one. After expansion ceases, gas, especially in the case of a soft seam, may continue to issue from the workings, but at a reduced and continuously decreasing rate.

The seam often expands suddenly. When it does, a rumbling sound like that of underground thunder makes itself heard. This sound is always accompanied by a concussion, plainly felt in the coal and adjoining strata. Simultaneously the coal is loosened at the face. Clouds

*Consulting Engineer.

of dust obscure the lights. The timbers suffer considerably from crushing. If one happens to lean against the coal or has his hand on the roof above, he feels a distinct shock, as he does under his feet. Extraordinary quantities of gas flood the return airways. The latter fact does not permit us to doubt that a close relationship exists between a sudden expansion and an extraordinary gas emission.

Until about ten years ago the majority of Belgian and French mining men were of the opinion that what has since come to be called seam expansion resulted from the action of high-pressure gas forcing its way in great abundance through the coal. This idea has gradually ceased to prevail since Morin published the result of his extensive research work concerning the effects of pressure on deep coal deposits. (See Bulletin de l'Industrie Minérale, Paris, December, 1912.)

Firm Coal Emits Gas Readily

It is a fact that in all cases where a uniformly gaseous seam contains zones of easily mined coal and others where the coal is hard, the coal of the firm description always emits its gas readily, none or practically none of it being found in the mined product reaching daylight. Not so with the other kind of coal; it retains its gas so tightly that days, weeks and even months may pass before it sheds the last of it. If, however, the latter coal be submitted to crushing, the gas it retains so tightly is emitted. It all comes out promptly if the grinding is sufficiently thorough.

This Morin proved. He took 4 kg. of hard, gaseous, freshly mined coal and submitted it to three successive grindings each of two hours' duration. During the first grinding, the coal emitted 13.683 liters of methane. The second and third operations yielded 2.302 liters and 1.660 liters, respectively, of the same gas. The total gas collected was 17.645 liters, making 4.410 liters per kilogram of coal. This is equivalent to 122 cu.in. of gas per pound of coal. Or, putting it otherwise, every cubic inch of that coal yielded practically 6 cu.in. of methane.

Easily mined coal, which is coal lacking in cohesion, is really crushed or expanded coal. Consequently Morin's tests indicate that coal must be expanded to cause it to yield its gas promptly. Hence the theory that the emission of gas causes expansion is no longer defensible.

Gas Pockets Are a Myth

Another ancient theory, the oldest of them all, I think, that gas stored under pressure in underground pockets is the cause of what is now known as seam expansion, was discarded long ago. No such pockets have ever been found, and none of the hundreds of blowouts that have occurred in Belgium has ever disclosed empty spaces larger than could be accounted for by the quantity of solid material which is ejected with the gas.

Sudden expansion and its accompaniment of underground thunder and timber crushing are far from being unknown in non-gaseous seams. But, beyond material damage and scaring timid souls, they do no harm. In seams subject to blowouts, sudden expansion always is an ominous sign, for it may be the beginning of a disastrous, death-dealing gas outburst. The subterranean noise, the breaking of the timbers, the jolt the men get from the strata, are a signal for everybody to seek safety by the shortest possible route.

Of the hundreds of blowouts concerning which survivors have been able to give detailed and reliable evidence, there is no record of a single one having failed to announce its imminence in the same way. Many are the men who, having gone several times through the same kind of experience, can remain sufficiently cool in the presence of danger to notice and remember what takes place. The cracking of the timbers has never failed to be reported as being simultaneous with the underground thunder. Scores of men have reported seeing the faces advance bodily toward them. Several have compared the coal thus moving to coke issuing from a byproduct oven, a natural comparison for men to make who, in many cases have to cross coke yards in going to and from work.

When a blowout occurs it follows the sudden expansion of the seam by only a few seconds. But, short as may be the notice given, it has saved thousands of lives in those Belgian collieries classed by that country's Department of Mines as being of the "third category." In this list are placed exclusively the mines operating in the group of seams that are subject to blowouts.

In all the mines of the third category auger holes varying in diameter from 2 to 3 in. are drilled in the solid ahead of the face. This is done to investigate the condition of the seam and to drain it at the same time of at least some of its gas.

Cleavage Joints Contain Gas

When a borehole is drilled across the joints of cleavage the reaching of every one of these joints by the auger is marked at the mouth of the hole by a puff of gas the strength and volume of which increases from cleavage to cleavage as the hole grows deeper, ending often by being strong enough to blow the dust produced by the auger 20 or 30 ft. to the rear.

When the hole is so placed and so directed that it runs between cleavages without running into any, the drillhole may be completed without the detection of gas. Sometimes the auger will run into coal so soft that drilling becomes surprisingly easy and rapid. In such cases, the gas always blows out of the borehole in great abundance and with terrific force.

A hole of this kind either stops itself promptly by caving or grows rapidly to a large diameter, reaching sometimes 15 or 20 in. or more and violently ejecting at the same time large quantities of fine coal and dirt together with large volumes of gas. This indicates that the coal has lost much of its cohesion, that the seam has suffered from crushing and that perhaps the coal was still being crushed at the time the hole was drilled. The crushing stage reached by the seam is indicated by the more or less fine condition of the solid materials ejected.

From the facts mentioned above as well as from others that will appear later the opinion now prevails among Belgian mining men that methane is present under two different conditions in all coal seams subject to blowouts:

First, as a free gas confined under more or less considerable pressure in the joints of cleavage, fissures and other empty mechanical spaces existing in the seam; second, under a special form making it, so to say, a part of the coal itself. This form, of which more will be said later, might be termed "latent methane." This is the gas that only expansion of the coal will liberate.

Whatever be the exact form under which latent methane exists in the coal, it seems safe to assume that it is one that is unstable except at pressures above that of the atmosphere. It also seems certain that the critical pressure of latent methane (the pressure at which, for such temperatures as rule in the coal, latent methane

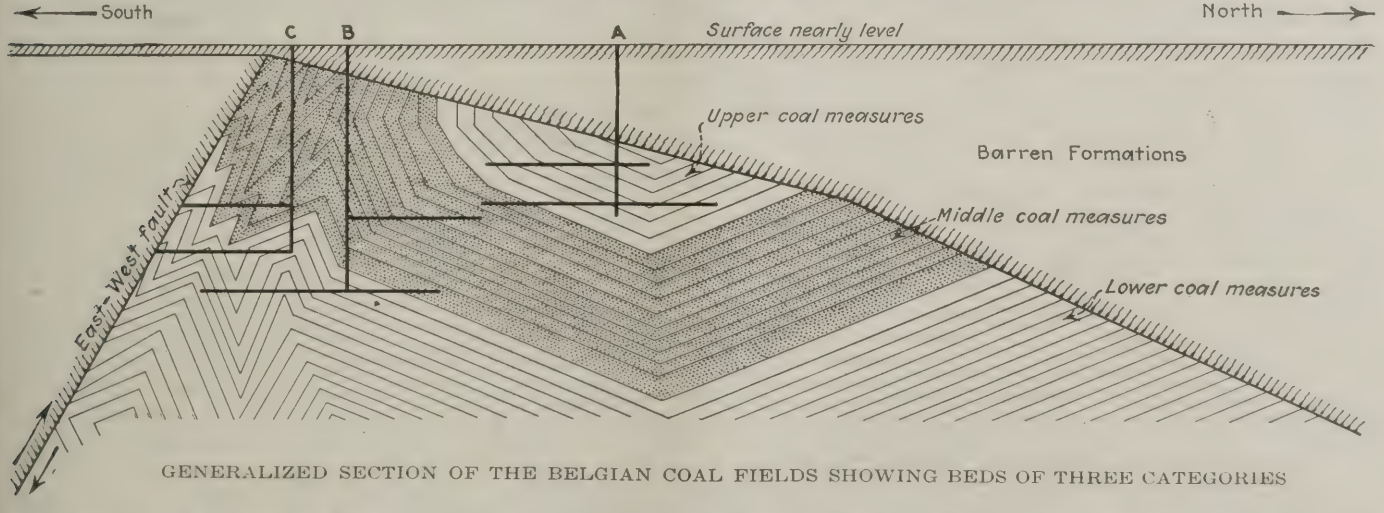
becomes free methane) is inferior to 42.5 atmospheres, which is the highest pressure ever recorded in Belgian seams subject to blowouts. This pressure was recorded by V. Watteyne and A. Macquet in the "Mouton" bed, at the Bellevue Shaft, in the Mons district of Belgium.

That the pressure is no higher disposes of a theory still given credence by some on both sides of the Atlantic. This theory is that latent methane is that gas in liquid form. Under such pressure as 42.5 atmospheres methane cannot exist in a liquid state except at the low temperature of —100 deg. C. (—148 deg. F.) The temperature of the coal measures in Belgian mines of the third category is certainly not less than 28 deg. C. (82.4 deg. F.), a temperature at which methane will not turn liquid unless subjected to a pressure of 350 atmospheres.

That which happens when a borehole reaches a body of crushed coal brings to the mind the well-known example of water at high temperature in a boiler. Vaporization stops when the pressure corresponding to the temperature of the boiler is reached. This pressure is called the critical pressure of water for the temperature considered. Now, if without changing this temperature, whatever it may be, a hole of small diameter be drilled through the side of the boiler, an emission of steam mixed with water will take place. Similarly, when a borehole penetrates a crushed part of a seam, gas is ejected mixed with fine coal and dirt.

To push the analogy further it may be remarked that, just as the escape of steam and water lowers the pressure in the boiler and re-establishes vaporization, so the discharge of gas, coal and dirt through the borehole lowers the pressure in the zone affected by the drilling below the point at which latent methane will become unstable at the temperature of the seam. All latent methane thus affected becomes free methane, which in turn in forcing its way through the borehole carries along with it some of the coal and slate of the zone from which it comes.

We all know that when for some accidental reason vaporization in a boiler becomes instantaneous, great mechanical forces come into play. It requires no great stretch of the imagination to understand that powerful mechanical effects similar to these are bound to result when in a large area of crushed coal, the ruling pressure falls everywhere at once sufficiently to permit all the latent methane present to become free methane. For this to happen the barrier of coal separating the mine workings from the high-pressure area of crushed coal must fail suddenly just as the shell of the boiler must fail if an explosion is to occur.



Many years ago the analogy between a boiler explosion and a mine blowout was used as the foundation for a theory that the later is in reality a case of instantaneous vaporization of liquid methane. This theory, however, was disproved, when it was shown, as previously explained, that methane cannot exist in a liquid state in seams subject to blowouts.

It is the pressure of the strata that causes a seam to expand. This pressure depends on the depth at which the seam is operated and the state of tension existing in the strata, including the seam, as a result of past geologic upheavals. What these disturbances have, in some typical cases done to the coal measures of Belgium is shown in the geologic section illustrating this article.

Uneven Geologic Pressures Have Existed

It makes evident the topsy-turvy conditions that predominate in those part of the Belgian coal fields where up to the present time, the seams subject to blowouts have been exclusively operated. The greater depths—4,000 ft. or more below the surface—where the same seams are expected to be found in regular formation have only just been reached.

Looking at the illustration it is not difficult to understand that some of these areas in the past may have been submitted to greater pressures that others. Even at the present time it is a fact of daily observation that there are in all seams subject to blowouts areas still under pressures that are entirely out of proportion to the weight of the overlying strata. This explains why

GENERALIZED SECTION OF THE BELGIAN COAL FIELDS SHOWING BEDS OF THREE CATEGORIES

Seams which do not generate gas are in the first category. Those in the second category generate gas but do not have blowouts. Those in the third category have blowouts and, of course, generate gas. The upper coal measures consist of thirty-five seams and are non-gaseous. In the illustration they are unstippled. The middle coal measures are all gaseous with the quality progressing with geologic depth. They number in all some eighty seams. These seams, which belong to the second category, are stippled in the illustration. The Lower Coal Measures likewise are not stippled in the illustration. All of them probably belong to the third category, though in what are known as the "flats," where the measures are not badly disturbed, blowouts may be less frequent. As these seams have not been extensively worked their number is unkown. It is, however, large. In shaft A, *bouveaux* have been driven at two levels. The upper-level workings are all in the first category, the lower-level workings to the north and part of those to the south being in seams of the first category. Some, however, are in the second category, having extended to the middle coal measures. In shaft B the workings on the *bouveaux* to the south are all gaseous but have no blowouts. Those connected to lower *bouveaux*, north and south, are nearly all subject to blowouts. In shaft C the *bouveaux* both run to the south and largely tap seams subject to blowouts, the lower *bouveaux* developing, however, none but seams of the third category. The folds in the seams to the south, badly contorted as they appear to be, are actually even more severely folded than the illustration shows, for the folds instead of being simple, as portrayed, have minor irregularities that the illustrator has not introduced because they are almost too small for portrayal, though they add greatly to the difficulties in operation.

in seams subject to blowouts the cohesion of the coal varies widely from one area to another. While in one area the coal may have remained comparatively hard, in the next it may have been pulverized so completely that, to use the miners' expression, "it runs like water." Any degree of crushing between these two conditions may be met in any area.

It is not uncommon at all for a *bouveau* to tap a seam at some point of an area sufficiently crushed for a blowout to take place then and there. It is not even always necessary in such a case actually to reach the seam before the interruption starts. I remember an occasion most vividly, probably because it was my first experience of the kind, when the face of a *bouveau* gave out without any of the holes bored ahead having touched the seam, although when I measured them barely two minutes before, the length of none of them was shorter than 3 m., or practically 10 ft. The seam, where it was struck by the *bouveau*, was practically vertical and the roadway intersected it at right angles.

I also remember a case, although I did not happen to be in the mine when it occurred, where after four boreholes had reached the seam at depths between 9 and 11 ft. a blowout occurred while the fifth and sixth holes were being drilled.

Many instances of blowouts occurring at the faces of *bouveaux* have been recorded. In every such case the usual eruption of gas mixed with fine coal and slate was preceded by the familiar underground thunder and the crushing of timbers.

In regular mine workings, in areas where the coal has remained hard or has not been badly crushed, conditions generally will remain reasonably safe so long as the faces do not reach too close to a dangerously crushed zone. Boreholes driven sometimes 10 m. (33 ft.) ahead have, so far, proved the best means of ascertaining the closeness of danger, although such holes have long ago demonstrated their uselessness for gas drainage purposes. Nor must one rely too much on the margin of safety which boreholes may seem to indicate. Boreholes 2 in. in diameter showing no activity at all in the morning, before the day shift goes home may blow gas in torrents and dust by the ton through openings enlarged to 15 or 20 in., and this may occur even without the holes having been drilled deeper in the meantime.

Squeeze Started Blowing

This probably is due to the fact that the boreholes in the first instance had reached close to a zone of badly crushed coal, that the barrier of safe coal remaining ahead of the men, critically thin and weak anyhow, was by the day's work further weakened and brought to a point where it ceased to offer sufficient resistance to the crushing action of the strata. A partial squeeze resulted that caused the dangerously crushed zone to grow sufficiently in extent to reach the inside ends of the boreholes, causing these to blow.

Eruptions of this kind follow by a short interval the usual thundering noise and cracking of timbers. The men flee in haste, although what is left of the barrier of safe coal sometimes resists until the fury of the manifestation has spent itself, which may take days, during which a large tonnage of fine coal and dirt will accumulate in the workings.

The results are much worse when the barrier of safe coal succumbs entirely to a squeeze. Then what constituted the barrier becomes as badly crushed as the zone immediately ahead, becomes in fact one with the said zone. Under the now unopposed action of the strata compressing it the whole body of crushed coal expands into the workings. The pressure ruling in the freed, nearly fluid mass drops suddenly to that of the mine, causing the latent methane in that mass to become free methane with a rapidity that reasonably can be termed instantaneous.

I have laid emphasis on the subterranean, thunderlike noise and the crushing of timbers that never fail to announce the imminence of a blowout because they afford proof of a sudden increase in the pressure of the strata. This augmentation in the stress results in the final expansion of the seam and this in turn creates the blowout. All mining men know that what I have designated as underground thunder means a settling of the strata. The breaking of the crossbars and the bending of the props mean that the strata in settling bear directly upon the workings and the seam.

Considering the topsy-turvy lay of the strata, the sudden settling that takes place may as well originate in the floor as in the roof side, or it may come from both sides at once. It matters little which, for the results are the same. At any rate only a guess could be made as to the source of the pressure, especially as the natural floor may be over the roof in some instances. The seams pitch at all possible angles from level to plumb vertical, the roof being as often under as above the men's feet, a fact that causes Belgian mining men to use one or the other term, geologic floor or mine floor, depending on the idea they wish to convey. For the same reason they differentiate also between geologic roof and mine roof.

A Squeeze Sometimes Starts from Below

That the sudden squeeze of the strata often proceeds from below is proved by countless instances of rocks being dislodged from the mine floor and thrown clear above it, only to be carried laterally sometimes for long distances by the force of the hurricane coming out of the seam. It must not be thought that the rocks thus carried far from their original locations are always small chunks of slate or sandrock. Masses weighing tons quite often are found to have been projected out of the mine floor and carried laterally over considerable distances.

A case in point I well remember. It occurred when, in 1896, I was visiting my old Belgian home. A block of sandrock found by measurement to weigh 3,700 kg. (more than 8,000 lb.) was thrown out of the mine pavement and carried up a 39-deg. incline, a distance of 10.5 m. (34.5 ft.) measured horizontally. This blowout occurred at the face of a slope in the coal at the Bellevue Shaft in the Mons district of Belgium.

The projection of rocks, large or small, out of the mine floor proves that the sudden squeeze of the workings and seam may come from below as well as from above. As such rocks could not be carried laterally by the blowout or any other agency unless first lifted above the mine pavement, it is clear that the lifting of the rock precedes the blowout. As the former is due to the same cause and occurs at the same time as the final crushing or expansion of the seam, it shows that the expansion precedes the blowout and is not the result of it, as was the general belief only a few short years ago.

The breaking of timbers and underground thunder are always accompanied by a puff of wind the intensity of which depends on the extent of the workings affected

by the sudden squeeze. This puff, called by the men "the first wind," is another phenomenon which the survivors always mention. It evidently is due to the sudden compression of the mine air by the squeezing of the measures.

Following on this comes the "second wind," which is incomparably stronger than the first and which is generally reported by the last of the fleeing men as coinciding with the report made by the final annihilation of the barrier of safe coal. The second wind, however, travels faster than the sound of the blowout itself. When giving their evidence as to what happened the men working at the shaft landing generally are unanimous in saying that they felt the second wind quite an appreciable time before hearing the report of the blowout.

The cagers often feel the second wind, despite the fact that, by reason of their distance from the seat of the blowout, they may fail to hear the sinister sound which accompanies it. This is interesting for in order to reach the hoisting shaft, which in Belgium is always the downcast, the second wind must be powerful enough to overcome the action of the fan.

Gas Traveled Back Against Air

In a number of instances the pull of the fan did not prevent a torrent of dustladen gas from reaching and ascending the hoisting shaft. Of course, a similar stream passes out by way of the upcast and through the fan. In 1879, when I was only a boy, an outburst occurred practically across the street from my Belgian home, and No. 2 Shaft of Agrappe colliery, Mons district, Belgium. To this day this disaster has remained unparalleled, at least in Belgium.

Perhaps on account of its strikingly spectacular features and the excitement it created, it gave a much-needed impetus to the study of blowouts and of the means by which they may be prevented or, at least, made less disastrous to life and property. Although ever since 1847 blowouts had occurred now and then in Belgian mines, they never had attracted much public attention, probably because the public was not allowed to learn much about them. Those were the days of conservative journalism in Belgium.

In the case of the Agrappe blowout streams of gas and dust ascended both the hoisting and fan shafts simultaneously. As usual at the time, the headframe and hoisting engine were in a large one-room brick building the walls of which were some 4 ft. thick at the base and not less than 2-brick thick under the eaves. In winter the place was carefully closed against the weather, except for a pair of openings in an iron floor, through which the coal was dumped onto the screens. These passages served as inlets for the air being drawn through the mine by the fan.

The day was cold. An immense coal fire was burning in a monumental fireplace behind the engineer's seat. No one who was unlucky enough to be in the building on that day came out alive. It is easy, nevertheless, to understand what took place in that engine house. The gas pouring out of the shaft spread rapidly through the almost tightly closed building, mixing with the air and finally igniting at the open fire. The building blew up like a bomb, gas at the mouth of the shaft, the diameter of which was 18 ft., continuing thereafter to blaze, as illuminating gas burns at the tip of a burner.

Burning more fiercely and brightly as it went up further and found more air, the immense gas jet sometimes reached a height of 200 ft., dying down only to ascend again after a few seconds, making all the time a tremendous roar and exploding at short intervals, with terrific violence and with a noise that could be heard for miles. The flame and especially the black clouds of dust that went with it were visible from the City of Mons. After two hours the great gas jet suddenly ceased to burn. The torrent of gas, however, continued to roar for five hours longer, throwing high into the air clouds of dust of varying blackness and thickness, and at intervals pieces of clothing and harness, fragments of mine cars and doors.

A large Guibal fan was used to ventilate the mine. The top of its chimney was only a few yards from the hoisting building. When the latter was demolished by the explosion, the gas pouring out of the chimney ignited, and another explosion occurred that put the fan out of commission. No more flame was seen thereafter at the chimney of the fan or at any other place round about it. To the present day this has been the only example in Belgium of a mine fan being disabled as a result of a blowout or any other kind of gas accident.

Surprising as it may seem and did seem at the time, out of 288 persons who were in the mine 42 came out alive. One was a woman. The last of the dead were not found until more than two months later, after the workings had been cleared of an immense tonnage of fine slack and dust that had penetrated everywhere, on the intake side as well as in the return airways as far as the fan shaft, the sump of the latter being filled with coal as was also that of the hoisting shaft on the very bottom of which the bodies of the cagers were found.

All Theories but One Disproved

What safety regulations were formulated and enforced as an immediate result of the Agrappe blowout will be mentioned in another article. The desirability of keeping this article within permissible limits does not allow a review of all the theories that have been advanced to explain the presence in coal seams of such enormous quantities of methane as are revealed by blowouts. With the exception of the Ruelle theory, the latest, which I now will try to explain, they have all been scientifically disproved. There is one, however, of those now obsolete theories that I desire to mention briefly for the reason that it was only quite recently that its definite refutation was made possible by Morin's experiments.

This theory is that the large quantities of methane found in the coal had been absorbed by it just as gases are absorbed by charcoal that has been allowed to cool in a vacuum. Such charcoal will absorb ninety times its own volume of ammonia gas, eighty-five times its volume of hydrochloric acid gas or large quantities of other gases.

It is admitted that the charcoal possesses this property of absorbing such great quantities of certain gases only by reason of its great porosity. Hard and compact carbon, like diamond and graphite, does not absorb any of the gases in any quantity whatever. This would show that the property of carbon to absorb certain gases depends wholly on its porosity. Evidently coal does not have the ability to absorb quantities of methane, for it is not porous until it has been expanded. But Morin has demonstrated that the capacity of coal to retain methane decreases as it expands.

Bold as at first may seem Ruelle's theory of latent methane, or polymethane, as he sometimes calls it, it

has the great merit of resting on a sound scientific basis, agreeing at the same time with all the facts and phenomena currently observed in connection with blowouts. This is much more than can ever be said of even the most plausible theories advanced in the past to explain the probable nature and real properties of the gas that causes seams of coal to blow out practically without notice.

Many Changes Accompanied Coal Formation

Ruelle, explaining his theory before the Mons Society of Mining Engineers, goes into a mass of comprehensive and detailed scientific explanation to which I feel unable to do justice in a statement sufficiently abbreviated to fit within the limits necessarily put on this article. However, the scientific data upon which he bases the few assumptions he makes are undisputed and can be found in all up-to-date chemical reference books. I must be satisfied with presenting the following short statement of the new theory.

Ruelle is of the opinion that in past geologic times, when the wooden substance called cellulose, that was later to become coal as we know it today, went through the decomposition process that caused it to liberate the gas known as methane, it was in a condition still soft and doughy enough to supply the water necessary to a dissolution of the methane liberated. At a later geologic period, under subterranean pressure, the cellulose became solid.

The same actions that caused the solidification process also caused the water to disappear, perhaps decomposing it into its elements, which were then absorbed in the reactions accompanying the process. The methane was thus again liberated. It still was left, however, in intimate contact with the molecules of hardened cellulose. When a substance separates under pressure from another in which it was dissolved it generally polymerizes.

Polymerization Depends on Pressure

Polymerism, as is well known, is a term generally applied to the phenomenon by which a chemical body having the same chemical composition as another chemical body has nevertheless fundamentally different physical properties. A substance that has thus been transformed physically by a change of either pressure or temperature or by both of these, will regain its original form and other properties as soon as a return is made to the original conditions of temperature and pressure. When this happens the substance is said to depolymerize.

For any substance polymerized under compression there is always a critical point. Let the pressure be reduced below a certain degree, and the substance will at once depolymerize and return to its former physical condition. According to Ruelle, methane separating under pressure from the water that was holding it in solution may have polymerized. It might take the form, perhaps, of microscopic crystals, perhaps of microscopic liquid vesicles, attaching themselves to the molecules of coal and becoming, so to speak, one with said molecules.

That being the case, only one action could separate the polymerized methane from the molecules of coal and that would be a reduction of pressure below the critical point. Morin's experiments have shown to what extent coal sometimes must be crushed before the last of its gas abandons it. Wholesale crushing of a coal area, causing it to spread into the mine workings, suddenly reduces the pressure below the critical point in the whole body of coal affected. Instantaneous depolymerization takes place through the coal and a blowout results, as has been explained already by the analogy between such a manifestation and a boiler explosion.

Importance of the Cement Industry As a Consumer of Coal

By J. S. Eaton.

AS THE fourth largest consumer of coal in the United States, the portland cement industry is a factor of growing importance in the demand for coal. Its position as a customer for bituminous directly follows the railroads, the iron and steel industry, and the public utilities. This rating so near the top may come as a surprise to many coal men who have not realized the large amount of fuel needed in making the country's cement.

Roughly speaking, one car of coal must be taken into a plant for every two of cement that are shipped out. Over half of this fuel is needed for burning the cement clinker, and the remainder is required in generating power for operating the heavy crushers, grinding mills, rotary kilns, conveyors and other equipment found in every mill.

The widespread activity in construction during 1922 sent cement production figures to new heights. According to data recently issued by the U. S. Geological Survey, the year's total was 113,870,000 barrels. In terms of the package almost universally used in shipping cement this means 455,480,000 sacks. Since crude oil is burned instead of coal in some parts of the country and natural gas also is employed to a small extent, the use of these fuels must be taken into account in estimating the coal consumed. With liberal allowances made for these substitutes, it appears that the coal consumption in the manufacture of cement was more than 8,500,000 tons in 1922.

The fuel requirements of the industry seem likely to become still greater, as the use of cement in all sorts of structures is increasing. In the two large fields of commercial building and roads this is especially marked. The manufacturers are already equipped to meet a considerably greater demand, for in 1920 the U. S. Geological Survey reported the producing capacity of the mills nearly 30 per cent above the record production of last year.

As building formerly was regarded strictly as a seasonal occupation, the demand for cement until recently has been largely concentrated in the six-months period May to October inclusive. The demand for new structures, however, has caused contractors to break through the prejudice against winter work, so that a large volume of construction is now carried on during cold weather. Much cement also is put in storage during this period against the peak demand. But the much greater summer activity normally results in a big demand for coal for cement manufacture throughout the warm months, when domestic and utility consumption drops off.

In all, as much as 200 lb. of coal or equivalent fuel is needed in making a single barrel of portland cement —that is, 50 lb. of coal to a 94-lb. sack. Expressed more vividly, for every sack of cement manufactured, nearly enough coal to fill that same sack must be bought.

Mining Seams Where Those Below Have Been Worked*

When Upper Seam Is About Twenty Feet Above Lower It Can Be Mined After Coal in Lower Bed Has Been Entirely Extracted —Do Not Work Upper Seam When Pillaring Seam Below It

By Howard N. Eavenson†
Pittsburgh, Pa.

IN MANY of the bituminous-coal districts of this country more than one seam of workable coal is found, and in most cases the lower seam is the more attractive, owing either to its greater thickness or its superior quality. Apprehension that the mining of a seam will destroy the availability of all overlying seams has hindered the development of many fields and has led to the unprofitable working of certain seams in order to save them from an expected total loss.

The United States Coal & Coke Co., Gary, W. Va., was the first operator in the Pocahontas field to mine the No. 4 seam extensively. This occurs about 80 ft. above No. 3, the seam which was worked first. No. 4 seam was worked at the Gary mines for the reason that over large areas that bed was the only one that was of a thickness which at that time could be mined at a profit. In two places both the seams were workable in the same area, the No. 4 being the thinner and containing more impurities than the No. 3 seam.

In mining these areas an attempt was made to keep the workings in the upper seam in advance of those in the lower one, and no pillar robbing was done in No. 3 seam until after pillars in that part of the upper seam directly over it had been mined. This resulted in an excessive development in the lower seam, with large areas of finished rooms and standing pillars. The top fell badly, and after a couple of years the falls became so heavy that pillar drawing was unduly expensive.

Made Investigatory Tour to Ascertain Facts

To overcome this obstacle and allow No. 3 seam to be worked in some territory where No. 4 was thick but too dirty for present use, a study was made of operating methods applied to superimposed seams in Pennsylvania and Maryland. I started this investigation more than seven years ago, and my data, supplemented by more recent information gathered by my associates and by two instances, the information regarding which is derived from recent foreign publications, form the basis of this paper.

In central Pennsylvania the lower coal measures contain several seams of nearly the same thickness but of varying quality, and as mining has been conducted here for many years, numerous instances can be found where an upper seam has been mined after a lower one. A general section of the measures in Cambria and Somerset counties is shown in Fig. 1. The coal seams vary from 3 to 5 ft. thick and occur at intervals of 40 to 80 ft.; the intervening rocks usually are shales, slates or sandstones. By correspondence with engineers, mine inspectors and operators it was learned that in many places an upper seam was being worked with no trouble after a lower seam had been mined. In four mines visited, a careful investigation in the upper mine failed to reveal any traces of damage caused by the removal of a 4-ft. seam 80 ft. below, and in one mine a heading over an area from which the pillars had been removed was of double-track width, without any posts and under good roof. In this mine it was reported that in driving the main heading in the upper seam, over a robbed area in the lower, a settlement of about 8 in. had been noticed, although the coal was in good condition. Rooms are driven 23 to 26 ft. wide with three rows of posts. It usually is necessary to drill holes to the lower seam to drain the water from the upper bed.

In another mine in this locality, recently examined, the *E* seam is being worked about 119 ft. above an area where the *C'* seam was removed some years ago. Above the *E* seam are 8 or 9 ft. of slates and shales under a 28-ft. layer of sandstone; the intervening strata are slates, shales, sandstones and the *D* seam, the latter being about 32 in. thick and lying 25 ft. above the *C'* seam. Mining was attempted in the *D* seam, but was abandoned on account of the damage done by mining the lower seam. In the *E* seam little settlement has occurred, but in certain places lying directly over robbed areas in the *C'* seam heavy falls occur, which frequently extend up to the sandstone. This does not happen where the *C'* seam has not been robbed. Cracks came up to this seam, draining the water off, but the overlying sandstone seems to be undamaged. Mining is considerably more expensive, due to the amount of dead work and timbering required, and the size of the coal produced is very fine.

One case was found where three seams in the same area were leased to three different operators, without any stipulation as to sequence of working, except that, if any settling was observed, protection should be left in the lower seams under the main headings driven in the seams above.

Two Thick Beds Worked Despite Small Interval

In southern Somerset County four mines are operating in the Redstone seam, immediately over the Pittsburgh coal. The latter seam averages about 8 ft. thick; the Redstone coal varies from 4 ft. to 4 ft. 10 in. and is overlaid by a fireclay 8 to 11 in. thick, bone and impure coal 14 to 20 in. thick, and a slate roof. Between the two seams the strata are mostly slate, which breaks readily into small pieces, but the actual bottom of the Redstone seam is a hard limestone from 2 to 6 in. thick. According to careful leveling, the distance from the top of the Pittsburgh to the bottom of the Redstone coal varies from 35 to 19 ft., the average being slightly over 26 ft. In general the headings in the upper seam are driven over those in the lower one, but sometimes this is not done; the headings are between 9 and 10 ft. wide. The fireclay over the coal is taken down and loaded out in both headings and rooms; the bone streak above this, wherever possible, is left up for a roof, and generally it stays up well. Where a heading or a room crosses a pillaring line in the lower seam, a break

*Article entitled "Mining an Upper Bituminous Seam After a Lower One Has Been Extracted," delivered at the New York meeting of the American Institute of Mining and Metallurgical Engineers, Feb. 19, 1923.

†Consulting engineer.

a few inches wide always is found in the seam and the top, the coal bending and dropping a maximum of 3 ft. vertically in a distance of 8 ft. horizontally. Fig. 2 shows this occurrence.

The experience in that district is that any two seams with this thickness of strata between them can be mined successfully if the lower seam has been entirely removed before mining the upper one; that the cost of mining the upper seam has not been increased perceptibly by the removal of the lower one; that the percentage of

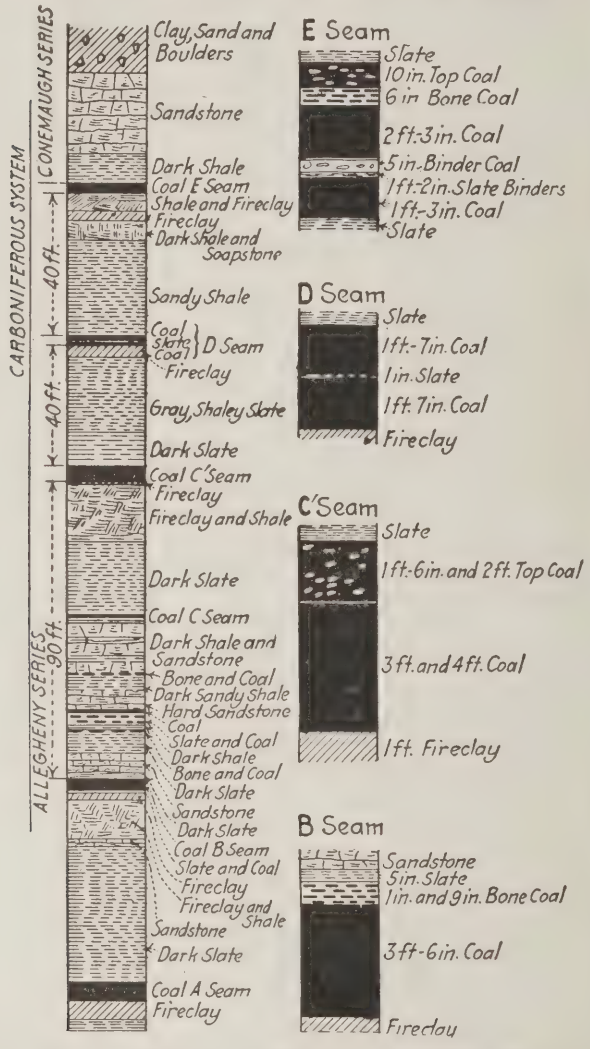


FIG. 1—SECTION OF STRATA AT PORTAGE, PA.

The *E* seam is being worked about 119 ft. above the area where the *C* was removed some years ago, the interval being 119 ft. Mining in the *D* seam, however, was tried and abandoned, owing to injury resulting from the removal of the *C* seam.

recovery has not been materially affected, nor has the element of danger been increased. It was the opinion that the upper seam could be worked three months after the lower one had been mined. It was generally necessary to drill holes to the lower seam to drain the water from the upper one.

At one mine the engineer for the lessor stated that 90 per cent of the coal was being recovered in the Redstone seam and that the cost of mining was not more than 4 to 6 per cent more than if the lower seam had not been mined. In view of the fact that the surface is often badly broken by the removal of pillars at depths of 200 ft. and more, the little damage done to the upper seam was almost unbelievable.

In the Georges Creek field in Maryland, and in the Connellsville region of Pennsylvania extensive mining is now being done in the Tyson or Sewickley seam in areas where the underlying Pittsburgh seam has been removed. In the Georges Creek field the Tyson seam varies from 28 to 36 in. thick; the top is a sandy slate or shale, which shoots well and stays up well. The Pittsburgh coal has a total thickness here of 14 to 16 ft., of which 12 to 14 ft. has been mined. The interval between the two seams is from 77 to 81 ft. and is composed of shales, slate and 16 ft. of sandstone. Very little attention has been paid to the location of the workings in the upper seam with regard to those below. In these mines the greatest damage found in the upper seam was in an area about 150 ft. wide. Here the roof was so badly broken to a height of 6 to 8 ft. above the coal that it would have been unsafe to drive rooms under it. This section was directly over a barrier pillar in the lower mine between one robbed section and another. The damage could not all have been due to the lower workings, as nowhere else could more than a few cracks be found, or a very infrequent break, similar to Fig. 2, but having a drop of only 18 in. The only other trouble experienced was where rooms or headings had been driven in the upper seam and robbing had been done afterward below them. The water from the upper seam usually drains through cracks to the lower one.

Surface Cracks Let in Disintegrating Water

In the Connellsville region, where the Sewickley seam is being worked, it has an average thickness of 5 ft., the Pittsburgh coal averaging 8 ft. The bottom of the Sewickley coal usually is a hard fireclay, although sometimes a thin slate occurs between the fireclay and the coal. The top is either limestone, sandstone or slate. The interval between the seams is 72 to 142 ft. of shales, sandstone, limestone and slate. Careful examination of thirteen mines in the upper seam showed the existence—over many robbed areas of the lower seam—of surface cracks in which percolating water and air had disintegrated the top rock, causing local falls sometimes as high as 4 ft. These conditions were not observed where robbing had not been done in the lower coal.

Gas was frequently noticed entering the upper seam from the mines below. Where sufficient time had elapsed after robbing the lower seam, nothing was found in the upper seam that indicated any material increase of cost or of danger, or a diminished recovery of coal. The surface over many of these mines had been broken by robbing in the Pittsburgh coal, but in spite of this numerous pools of water, in one case covering an area of several acres, accumulated in the upper seam and had to be removed by pumping. These pools were over areas which had been mined out by the H. C. Frick Coke Co.

In two cases where the upper seam had been developed first, when robbing was done in the lower seam, subsidence of 3 to 4½ ft., with heavy roof falls, occurred in the upper one.

During recent years in the Pocahontas field the coal in the No. 3 seam has been worked in several instances. In one case, No. 4 seam, with an average thickness of 4 ft., is being worked over an area where the lower seam, 5 ft. 5 in. thick, has been robbed. The roof of the upper seam is 5 ft. of slate under heavy sandstone; the bottom is 3 ft. of fireclay. The interval of 60 ft. is mainly sandstone, with some slate. Robbing in the lower seam produced no visible effects in the upper except possibly some roof falls, which, however, were not different from those usually expected with that kind

of roof. There is some question in this case as to whether the robbing in the lower seam had been thorough enough to cause serious falls.

In another mine, No. 6 seam, averaging 3 ft. 8 in. thick, with sandstone top and fireclay bottom, is being worked where No. 3 seam, 5 ft. 9 in. thick, has been mined beneath it; the interval of 150 ft. is almost entirely sandstone, except a few feet of slate over the lower seam. The only evidences of disturbance in the upper seam are in two places where subsidence and roof falls occurred, the robbing in the lower seam having been done after the workings in the upper were driven. In all other places conditions in the upper seam appear normal and water frequently collects over robbed areas.

In still another mine, a higher seam, about 340 ft. above No. 3, is being worked where the lower seam has been entirely removed. The only trouble here has been due to surface cracks which allow water to enter the mine, from which it does not drain well to the lower seam. In a mine in southwest Virginia, robbing in a seam 5 ft. 10 in. thick caused cracks in the surface 570 to 794 ft. above, along a line more than 1,000 ft. long. An upper seam occurs 445 ft. above the lower one, and some trial headings were driven in this to learn the extent of the expected damage done by the robbing. Except for some cracks, through which air came from the lower workings, absolutely nothing was found in the upper seam, either in levels or in the character of the coal, to indicate that the lower seam had been removed.

In a paper by William Taylor Heslop* the following experience at St. Georges colliery, Natal, is described. There are two seams here, the top one about 4 ft. thick; the bottom one, including 9 in. of carbonaceous shale, has a total thickness of 5½ ft. Between the two seams is a bed of laminated sandstone, varying from 3 to 5 ft. thick. The immediate roof of the upper seam is about 17 ft. of shale, the total cover being 250 to 350 ft. of interbedded sandstones and shales. The seams are approximately level. At first the top seam was totally extracted from about 8 acres, and the area was allowed to settle for two years before the bottom seam was started. Several trials of this scheme, with both room-and-pillar and longwall mining, showed that the weight of the gob on the intervening sandstone caused trouble and loss of coal when working the bottom seam. The plan finally adopted was to drive all workings in the bottom seam, connecting the haulageways by inclines to the top seam. The bottom seam was developed by blocking it into pillars 39x75 ft., the working places being 15 ft. wide. The top seam was then developed in the same way, the workings being exactly over those below. When robbing commenced, a lift 18 ft. wide was driven 39 ft. across the end of the top pillar; when this was completed and the fall had occurred, a corresponding lift was driven in the bottom seam, making the gob line in the top never more than 33 ft. (18 ft. lift plus 15 ft. working place) in advance of the bottom seam. The overhang of the solid roof protected the working lifts, and the sandstone between the two seams protected the lower lift from the gob above.

In a paper before the Mining Institute of Scotland, Dec. 9, 1922, the following experiences are described. Near Glasgow, the Main and the Jewell seams lie about 710 ft. below the surface. The Jewell seam, the lower one, is 22 in. thick and is separated from the Main seam, which is 24 in. thick, by 4 ft. of fireclay. In some places the upper seam was worked first, but in one place the bottom seam had been worked out for about three years before work started in the upper seam. The upper coal was found to be friable and produced much slack; although the roof was hard, it was broken, as a result of the first working, and the roads were difficult to keep open. The bottom, being soft, had a tendency to heave, and in some places it had dropped away from the coal. Care had to be taken when the mining machine was crossing an old road in the lower seam. By this method less timber was required and less dirt was produced than when the lower coal was worked after the upper coal had been taken out.

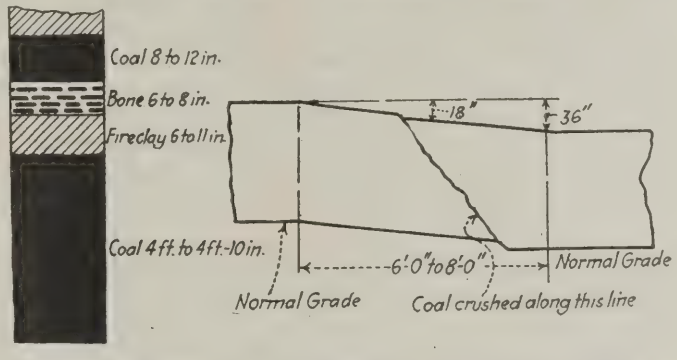

FIG. 2—BREAK IN UNDERMINED REDSTONE SEAM

How the coal breaks over the point where the work of removing pillars in the lower, or Pittsburgh, seam commenced. The interval between the seams is from 19 to 35 ft. and the Pittsburgh seam is 8 ft. thick, yet at one mine 90 per cent of the Redstone seam is recovered, and the cost of mining is not more than 4 to 6 per cent above that it would be if the lower seam had not been mined.

The table shows the comparative costs of mining in both seams and under both conditions, x representing the lowest cost. The shilling has been figured as equivalent to 24c.

The statement is made that when either seam is worked the other is more or less damaged, to an extent depending upon the nature of the strata. Where the top seam was worked first the damage consisted in hardening the coal, which was of no importance when machines were used. Where the bottom seam has been worked first, the damage consists in a large percentage of slack, which is not objectionable if the coal is for coking purposes. "Hence, one might say that the injury would be either real or apparent, according to condition."

Experience in all the above-mentioned localities seems to warrant the following conclusions: (1) Mining an upper seam after a lower one has been removed can almost always be successfully done when the thickness of intervening strata is 19 ft. or more. (2) The lower

Journal, Chemical, Metallurgical and Mining Society of South Africa, October, 1921.

Section	Output per Shift at Coal Face, Lb.	Miners' Wage Rate, Cents	Machine Cutting, per Ton, Cents	Brushing, per Ton, Cents	Repairs and Overhead, Cents	Total Cost, Cents	Timber Cost Cents
Main (top) coal, where bottom is mined out	3,277	x+ 19.8	x+ 5.0	x+ 6.4	x	x+ 27.2	x+ 1.2
Main (top) coal, solid	6,101	x	x	x	x+ 3.1	x	x
Jewell (bottom) coal, solid	2,975	x+ 63.2	pick places	x+ 3.1	x+ 8.7	x+ 47.2	x+ 0.6

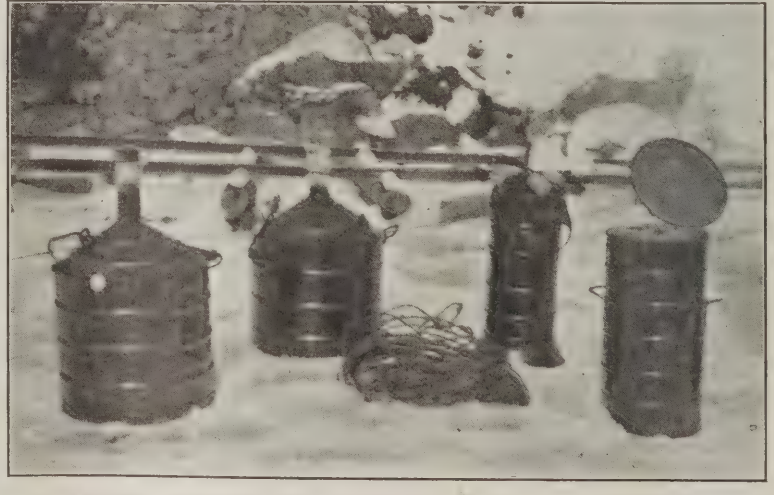
seam should be entirely removed from any area, and time should be allowed for settlement before working is started in the upper seam; the more complete the extraction, the less will be the likelihood of trouble in the upper seam. (3) Working in an upper seam should not be attempted while removing the pillars in a seam below it. (4) Percentage of recovery in an upper seam will not be materially reduced nor the cost or danger of mining be greatly increased because a lower seam has been removed.

Liquid-Oxygen Explosive Is Demonstrated At Martinsburg, W. Va.

AS FLAME is generated by the explosion of liquid oxygen it is hardly likely that the explosive will ever be recommended for use in blasting coal. It has been used for that purpose in Germany, but reports are that its employment is declining. However, enough shooting takes place at coal strippings, in tunnels and on mine railroad switches, surface tramroads and in general excavation work to make the possibilities of using liquid oxygen important to the industry and worthy of note.

The Germans are ardent advocates of using for this purpose carbon and oxygen of great purity. Frequently the oxygen they use runs 99 per cent pure, but that prepared for this purpose at the Real del Monte y Pachuca Co.'s mine at Pachuca, Mex., is slightly more than 95 per cent pure. The company mentioned is a subsidiary of the United States Smelting, Refining & Mining Co. The lampblack by which the liquid oxygen is absorbed is made by the combustion of *chapopote*, a residual gum of petroleum found in the crude state in the Mexican oil fields. This being an impure product absorbs in a ratio of 4:1 as compared to 4½:1 ratio attained with purer forms of carbon used by the Germans. They use burned cork for their carbon cartridges.

The oxygen at the Pachuca mine is prepared by an ordinary Mexican laborer and boy, so simple is the method of manufacture. The maximum pressure used in the process is 2,800 lb. The air is compressed until liquefied and then the pressure being lowered, the nitrogen, which is more volatile than oxygen, boils off, leaving a steel-blue liquid oxygen about 95 per cent pure. The Pachuca plant uses a 100-hp. motor for the liquefaction of the air and produces thirty-six cans of liquid oxygen per eight-hour shift, each containing 12 kg., or 26.45 lb., of oxygen. This is almost 1,000 lb. The gases formed are not visible. They consist of carbon dioxide. It is stated that no carbon monoxide is formed where the cartridges are properly saturated.



The first public demonstration in this country of blasting with this explosive took place Feb. 7 at the quarry of the Kelley Island Lime & Stone Co., about two miles west of Martinsburg, in the Panhandle of West Virginia. The tests, which were arranged by the U. S. Bureau of Mines were conducted by Adolph Messer, head of the German firm of Messer & Co., who has been in this country on business. This explosive in general is made by soaking sticks of carbon in liquid oxygen on the spot where the blasting is to be done. The holes are then loaded with the saturated cartridges as quickly as possible, and blasting follows with the minimum loss of time, either electric exploders or the ordinary cap and fuse being employed. Blasting must follow quickly after the cartridges are removed from the soaking receptacle, because the evaporation of the oxygen soon renders them inert.

The liquid oxygen used was made at the plant of the Southern Oxygen Co., Washington, D. C., from which it was taken between 1 and 5 p.m., Monday, Feb. 5, and conveyed to the quarry at Martinsburg in double-wall vacuum-bottle containers most of which held about 35 lb. of the liquid. The flasks are not corked but have a hinged perforated metal cap. Oxygen is steadily lost from the containers by evaporation. By 7:30 a.m. Tuesday, Feb. 6, the average loss, according to the representative of the oxygen company, was 1½ lb. per 35-lb. container. The loss, it was stated, averages less than 0.5 per cent per hour; this despite the fact that the container is open to the air. Corking or closing of the container will result in its breakage.

Some of the "Lampblack" Mixed With Cork

Carbon cartridges of two kinds were used in the tests. One (D2) consisted of pure acetylene lampblack, and the other (A2) was composed of the same material mixed with 25 per cent unburned ground cork. The former, according to Mr. Messer, is considered equivalent, when impregnated, to 80 per cent dynamite, and the latter to 60 per cent dynamite. The lampblack was loosely wrapped in blotting paper so as to form roughly cylindrical sticks, 300 mm. (about 12 in.) long, and 35 or 40 mm. (1⅜ to 1½ in.) in diameter. These sticks before soaking in oxygen can be compressed easily with the fingers. After soaking they are frozen and brittle. Most of the cartridges used in the test were 40 x 300 mm. (1½ x 12 in.), each containing 75 gm. (2¾ oz.) of pure lampblack. Immediately after soaking they weighed about ¾ lb. each, indicating a ratio of absorption of about 3½:1.

No. 8 electric exploders were used in the principal tests, one to each hole or charge. The cap was inserted in a hole bored through a wood cylinder or plug about 4 in. long and somewhat less in diameter than the drill-hole. Cap and plug were then lowered into the hole by the leads until they rested on the charge. Firing was

BLASTING EQUIPMENT ASSEMBLED AT COLLARS OF HOLES

done with a No. 4 blasting machine of the Aetna Explosives Co.

The program included the blasting of one round of two holes, one of three holes, one "block shot," and two "pasters" or "mud caps." The two holes shot first were about 2 in. in diameter at the bottom and 20 ft. deep, drilled almost vertically and 10 ft. back of the quarry face. They reached practically to the level of the quarry floor, and at that level were approximately as far in from the face as at the top. The cartridges were prepared close to the collar of the hole. The equipment assembled for this purpose is shown in Fig. 1. Carbon sticks were placed upright in the double-walled soaking containers, which held from twelve to eighteen sticks, according to size. Liquid oxygen was then poured in from the oxygen container, flowing in a small steel-blue stream from the orifice. Rapid evaporation accompanied the pouring. The soaking cans were then closed and the sticks allowed to soak for about fifteen minutes. At least six minutes is required for proper soaking, according to the representative of the oxygen company and oversoaking is better than undersoaking.

Oxygen Rapidly Evaporates in Borehole

The cartridges were then removed one by one, as frozen sticks, from the can and dropped into the hole. If properly soaked, the entire cartridge should be saturated, though the bottom will be supersaturated. Immediately there was a rapid evolution of vapor from the hole, demonstrating the rapidity with which oxygen was being lost. Eighteen D2 cartridges were used in each hole. The charge was then carefully packed down with a long wooden tamping rod. The electric exploder and wood cylinder described above were lowered into each hole, a half powder box of fine sand poured in by way of tamping, the wires tested, and the blast fired. Loading consumed four minutes and the blast was fired within seven minutes after the first cartridge was dropped. Three men were employed in loading the two holes.

As a result of the blast, the ground was badly shattered over an area extending 15 ft. back of the face and 50 ft. along it. A moderate tonnage was thrown into the quarry pit. The general impression created, however, was favorable.

In the second test, three holes, respectively 20 ft., 16 ft., and 20 ft. deep, drilled almost straight down and 7 ft. apart in a line parallel with the quarry face and 8 ft. back of it, were loaded as before. The cartridges were soaked nineteen minutes, and two men loaded the three holes in six minutes. Sixteen ¾-lb. sticks were placed in each 20-ft. hole and 12 sticks in the 16-ft. hole. The blast failed, however, though all three of the detonators exploded. This was explained by the theory that the evolution of gas from the charge lifted the wood cylinders by which the detonators were held, thus permitting the sand tamping to get between the exploders and the charge. Some even say that the detonators were thrown out of the holes.

After an hour had elapsed the inert carbon charges were easily blown out of the holes with compressed air. The 16-ft. hole and one of the 20-ft. holes were then reloaded. Soaking took fifteen minutes and loading three minutes, two men loading the 20-ft. hole and one man the 16-ft. hole. The third hole was abandoned because of insufficient oxygen. The manner of loading was changed in this test. Twelve cartridges were put in each hole before the electric detonator. Most of them

QUARRY OF KELLEY ISLAND LIME & STONE CO.
The tests with liquid oxygen were made in this quarry under the direction of the U. S. Bureau of Mines. One round of two holes, one of four holes and two "pasters," or "mud caps," were fired.

were of the A2 variety, containing 25 per cent ground cork and 75 per cent acetylene lampblack. On top of each exploder were then placed three D2 cartridges, followed by two A2 cartridges. Sand tamping was again used.

Before loading was finished, difficulty was experienced by the action of the escaping gas in blowing the sand and some of the topmost cartridges from the holes. These were finally wedged in and the charge was blasted. One hole broke well. The other was again a failure, giving a pyrotechnic display as flame from it spurted into the air. The opinion was expressed by Mr. Messer that the use of sand was evidently a mistake, though the first time it gave no trouble.

A "paster" or "bud-cap" shot gave remarkable results in shattering a huge block of stone in the quarry pit. Ten sticks of D2 explosive were fired with 8X cap and fuse. Two other minor tests gave good results.

During the tests the oxygen and cartridges used were not weighed, so that the total quantity of explosive used could only be gaged approximately in terms of "cartridges."

Preparation of Electrical Mine-Safety Codes.—The Electrical Section of the U. S. Bureau of Mines has done considerable work in connection with the preparation and the compilation of data relating to safety rules and regulations for the installation of electrical equipment in mines. The following publications relate to this question:

- Technical Paper 133, "Suggested Safety Rules for Installing and Using Electrical Equipment in Bituminous-Coal Mines."
- Technical Paper 271, "State Mining Laws on the Use of Electricity in and About Coal Mines."
- Serial 2224, "State Regulations on Accident Prevention Covering Electric Circuits in Coal Mines."
- Serial 2258, "State Safety Regulations Governing Mine Telephones."
- Serial 2405, "State and Federal Electrical Shotfiring Regulations."
- Serial 2419, "Regulations Safeguarding Coal-Cutting Machines."

In addition to the above, tentative codes for the installation of electrical equipment in both coal and metal mines have been prepared. Copies of these codes can be obtained by any commission having the revision of state mine regulations under consideration.

Problems of Operating Men

Edited by James T. Beard

Warning Against Mine Explosions

Frequency of Mine Explosions Increased Since the Strike—Mine Workers Cautioned to Avoid All Unsafe Practices in the Mine

THAT mine explosions have been on the increase, both in this country and abroad, during the past six or eight months, is not to be denied. In this country, it is natural to claim that the strike of the miners is, at least, one of the contributory causes for this condition, although there may be and probably are other causes for the increased frequency of these dread disasters.

I have read with interest the warning given out by the Chief of the Bureau of Mines, drawing attention to this matter. Certainly the appeal to awaken the slumbering regard of mine workers to this danger cannot be made too strongly. At the present time, there is little that is of greater importance than to arouse the interest of every mining man, from the official in the office to the miner at the coal face, and solicit their co-operation in efforts to make the mine safer.

While the six explosions mentioned in the warning to which I have referred resulted in the killing of 185 men, this sad accounting does not include the several smaller explosions that are taking place in our mines each week and killing from one to five men apiece.

Local Explosions Cost Many Lives

If the whole story could be written, it would appear that there are occurring daily, in the mines many local explosions that, by the merest chance, do not extend further than a short distance from the place of their origin. That such is the case cannot be said to be due to good management. It is what most men call "luck" and a few a "merciful providence."

To the practical miner, the causes of these happenings are not mysterious. He knows that the following of a bad practice will sooner or later bring disaster. At the same time, almost without exception, the miner chooses to follow the easy way, instead of using the precaution that he would recommend to others and which he knows are essential to safety.

In other words, the average miner takes the chance in innumerable instances. He follows the line of least resistance that, while it may get results today, makes no promise for the morrow. Such, I regret to say, is the attitude of mind of the major portion of our miners toward their work, today.

The Foreman Knows But Trusts to Luck

Every mine boss knows whether the working places in the mine of which he has charge are being adequately ventilated. Most of these bosses know, also, the condition of the gob. They may feign some surprise when told of a dangerous condition existing in a portion of their mine. But, if the truth was known, the information afforded is nothing new to them. They have known of the condition for some time, but are trusting to luck, ignoring the danger while devoting themselves wholly to getting out the coal.

A miner's working place should be the safest place in the mine and any half-hearted, indifferent attitude on his part should not be tolerated. Again, failure on the part of the foreman to provide sufficient supplies and preserve a healthful and safe working condition must likewise not be tolerated. But who, let me ask, is to be held responsible for enforcing these conditions?

While it is not my disposition to throw responsibility that should rest on one party, onto the shoulders of another, it is my belief that there is no agency better able to enforce discipline in our mines than the State Department of Mines. The law gives them the power and their authority is widely respected. Let me close by stating that when the state realizes its responsibility for maintaining discipline in the mine, the occurrence of accidents and disasters will be less frequent.

Pikeville, Ky. George Edwards.

Conditions That Invite Mine Explosions

Circulation not sufficient to dilute and sweep away gases generated—Air current not made to sweep the working faces—Large abandoned areas standing open.

MANY mine disasters occurring recently cause us to ask ourselves, again, what are the causes that lead to these occurrences? Though it is a well worn subject, a brief reference to some of the general causes or conditions that invite explosions in mines will not be out of place at this time.

All must agree that one of the principal causes of explosions of gas or dust, in mines, is an insufficiency of ventilation. The volume of air in circulation may be sufficient to comply with the requirements of the mining law and yet not enough to dilute and sweep away the gases generated in the workings of a mine.

Locked Safety Lamps No Excuse for Inadequate Ventilation

No practical mining man will deny that such a condition invites disaster. The fact that a mine is being worked with locked safety lamps of an approved type is no excuse for inadequate ventilation and any attempt to operate such a mine when poorly ventilated is but taking a gambler's chance.

Another chief cause of the ignition of gas and dust present in the workings of a mine is the failure to properly conduct and distribute the air current throughout the mine. The fact that the *volume* of air entering a mine is all that is required to make the workings safe does not prove that the mine is properly ventilated.

Efficient ventilation means that the air entering the mine is distributed to the several ventilation districts in proportion to the need of each district. Not only that, but the air current must be made to sweep the

working face with sufficient velocity to dislodge and carry away what gases would otherwise accumulate there.

This will often require the erection of brattices, in rooms and working places, so as to conduct the air forward from the last breakthrough. In some cases, it may be necessary to erect a special brattice to deflect the air into some cavity of the roof or other void place.

A third and very important condition that invites disaster is permitting large abandoned areas to stand open, or attempting to ventilate them by passing the air current through such places and then permitting it to enter other places where men are at work.

Danger When Air Passes Over Falls

Safety requires that when a room, or a number of rooms forming a section of the mine, have been worked out and the pillars drawn such places should not be left to stand open without being properly ventilated. If they are ventilated the current passing through them should be conducted at once into the main return airway where it will pass out of the mine without reaching other working places.

Not long ago, I had taken charge of a mine where the ventilating current passed over many falls in the worked out section, before it reached the rooms where men were at work. In that mine, when the coal was taken out and the roof caved much gas would be given off.

The mine was worked with open lights and, while I took every precaution to keep the dust wet and the roadways clean, in my opinion, the place was not safe. I therefore requested the superintendent of the mine to allow me to change the circulation so as to ventilate the live workings with fresh air and conduct the air sweeping the falls directly out of the mine. This being refused I resigned my position and left the mine.

In closing, let me say that attention given to these and other points of equal significance will greatly reduce and perhaps wholly eliminate the disasters that are now so frequent in coal mining. C. W. Atkins.

Parnassus, Pa.

Overcoming Bumps and Outbursts of Gas Occurring in Mines

Suggestion of storing waste by flushing not effective—Outbursts occur in advance workings—Not known in worked-out sections.

KINDLY permit me to refer to the letter signed "M. E." and entitled "Gas Menace in Mines," which appeared in *Coal Age*, Dec. 21, p. 1001. In the latter part of the letter the writer refers to the occurrence of bumps and outbursts of gas in mines.

In his closing paragraph, the writer makes a suggestion that is worthy of comment, because of its evident inapplicability as a means of preventing these occurrences. It would seem, that, in making the suggestion, the writer did not stop to give the matter a second thought, or he would not have asked if the proposition was feasible.

After speaking of the danger of such occurrences, he states as follows: "In the same connection let me suggest the practicability of the stowing of waste in the worked-out portions of mines, by the hydraulic process, which some may style 'flushing.' Such a stowing of waste might prove an effective means of eliminating both bumps and outbursts of gas."

There are few mining men who have not heard of the use of flushing as a means of aiding in the recovery of pillars, under conditions that made it impossible to extract them in any other way. However, this is the first time that I have read of flushing being recommended for the elimination of bumps and blowouts in mines.

No Knowledge of Outbursts of Gas Having Occurred in Old Workings

Though I have read of many outbursts of gas in mines in various localities and have investigated a number of them, in no single instance have these occurred in the worked-out portion of a mine. On the contrary, they have always occurred in the advance workings with which they are or seem to be associated.

Taking these facts into consideration, it is difficult to understand the ground on which this suggestion is based; or was it merely a passing thought that escaped the writer before he had given it special attention?

Previously, in his letter, the writer remarked, "While bumps in mines are dangerous, they are far less so than many outbursts of gas that have occurred. In some instances, the outburst has thrown down tons of coal and filled the mine passageways with gas and suffocating dust."

From this statement, it would appear that the writer recognized the fact that these occurrences took place, at least commonly, in the live workings of a mine. It would be interesting to know if our friend has any knowledge of such occurrences ever having taken place in worked-out sections. Assuming that he gave the matter any serious thought, it seems possible that he may have experienced occurrences of this nature in sections where the stowing of waste would have prevented their occurrence.

Before closing, allow me to ask the writer to whom I have referred, if he considers that flushing would have any material value in certain European mines, where outbursts have occurred in the advance workings, both in the bord and pillar and longwall systems of mining. Again, does he seriously think that flushing could have been applied with advantage in the mines of British Columbia, where large outbursts have occurred at Morrisey and elsewhere? R. W. H.

Victoria, B. C.

Solution by Equivalent Orifice

Ventilation of shaft mine increased by adding another airway—Cube of the quantity of air passing varies as the square of the equivalent orifice.

REFERRING to the solution given to a difficult examination question, asking what increase of air in a shaft mine would result from the addition of another airway of the same size and length as the one already in use, *Coal Age*, Dec. 21, p. 1002, permit me to offer the following solution obtained by the use of the equivalent-orifice method.

The *Coal Age* journal is much appreciated here and read from A to Z; and it seemed to me that the following solution would be of interest to many students of ventilation. I will endeavor to give it as simply and briefly as possible, omitting unnecessary explanations.

The question referred to assumes a circulation of 10,000 cu.ft. of air per minute, passing in a single split in a shaft mine, and makes the resistance of the two shafts equal to that of the original airway. Then, assuming a constant power on the air, it is desired to

ascertain how much the circulation in the mine would be increased by the addition of a second airway of the same size and length as the first.

Applying the equivalent-orifice method, let A represent the equivalent orifice of the combined shafts and the original airway, when the air is passing in a single split; and let a and a_1 represent the respective orifices of the two shafts and the original airway. Then it can be shown that

$$\frac{1}{A^2} = \frac{1}{a^2} + \frac{1}{a_1^2} = \frac{2}{a^2} \qquad (1)$$

remembering that a is equal to a_1, since the resistance of the two shafts is equal to that of the original airway.

Again, let A_1 represent the equivalent orifice of the combined shafts and the two airways, after a second airway has been added of the same proportions as the first. In this case we have

$$\frac{1}{A_1^2} = \frac{1}{a^2} + \frac{1}{(2a_1)^2} = \frac{5}{4a^2} \qquad (2)$$

Now dividing equation 1 by equation 2, we have for the ratio of the squares of the equivalent orifice of the mine, before and after the change is made.

$$\frac{A_1^2}{A^2} = \frac{2}{a^2} \times \frac{4a^2}{5} = 1.6$$

But, for the same power on the air, it can be shown that the cube of the quantity of air in circulation varies as the square of the equivalent orifice of the mine. In other words, the cube of the quantity ratio is equal to the square of the orifice ratio. Hence, the original circulation being 10,000 cu.ft. per min. and letting Q represent the increased circulation after the second airway is added, we have

$$\left(\frac{Q}{10{,}000}\right)^3 = \left(\frac{A_1}{A}\right)^2 = 1.6$$

and $Q = 10{,}000\ \sqrt[3]{1.6}$

$= 10{,}000 \times 1.1696 = 11{,}696$ *cu.ft. per min.*

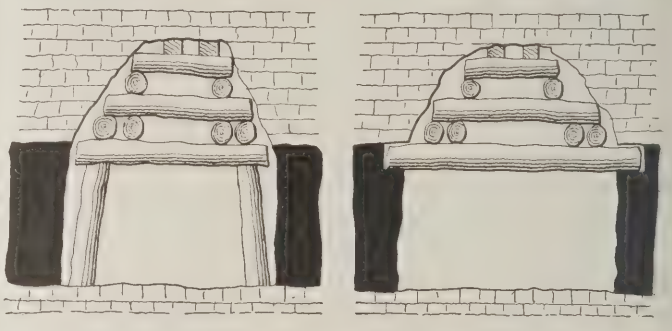
Inquiries Of General Interest

Retimbering an Old Slope When Opening a Longwall Mine



Slope 8 Ft. Wide, 500 Ft. Long, Dipping 20 Deg. Needs Retimbering—Should Crossbars be Set in Hitches or Supported on Legs?

A PROPOSITION that has given me some little concern, recently, is the retimbering of a 500-ft. slope, at one of our mines. The slope is driven 8-ft. wide and dips 20 deg. Including the slate in the coal, the height of the seam is about 4 ft. The coal is overlaid with a soft roof. When the slope was driven, the roof was not brushed, but was timbered in the usual way with double timbering, the collar beams being supported on two legs. At the present time, the weight is breaking the timbers and the frail soapstone roof is falling to a considerable height above the road.

When this slope has been retimbered and is in shape to be used it is the intention to open out a longwall face at the foot of the incline. The roads or gateways will be driven across the pitch, so as to provide a suitable grade for handling the cars, which will then be hoisted up the slope.

The work of retimbering was started at the foot of the slope and had proceeded but a short distance when it occurred to me that we were making a mistake in choosing the wrong method of supporting the crossbars. The plan we had selected is illustrated on the left of the accompanying figure.

As there shown, the crossbars are supported on two legs. The timber frames are set about 3 ft. apart and heavy stringers or poles were used as lagging to span the space between. As shown, other cross-timbers were

TWO WAYS OF SUPPORTING ROOF TIMBERS

then laid above the lagging and this system was continued up to the solid formation above.

In this work, the old timbers are being used to fill the space previously occupied by the fallen material. The work looked good and we had imagined that the job was fairly well executed as far as it had gone. Pondering on the matter, however, has caused a doubt in my mind as to whether we have chosen the right method of supporting the crossbars.

It seems to me now that these should rest in hitches cut in the solid coal, as shown on the right of the figure, instead of employing double timber and resting the collars on the legs. What appeals to me is that, not only would we have saved the timber used for the legs, but all the timbers would settle more uniformly with the strata and excessive strains would be avoided had we chosen this second method of supporting the crossbars.

The question that puzzles me is to know whether my reasoning is correct. It seems to me that when the coal is taken out and the overburden settles on the gob, we can expect nothing but that the legs of the timber frames will be broken and the topping above the collars fall into the road.

To my mind, such a result is what is liable to occur in the adoption of the first method mentioned. Since it is most important to maintain a good roof over the main slope, we are anxious to have the views of *Coal Age* and its practical readers, as to the safest method of proceeding. The problem may be a simple one, but it appears to me as being worthy of discussion.

River Herbert West, N. S. MAC.

Although the correspondent has mentioned his intention of opening a longwall face at the foot of the slope it is possible that he has in mind extending the longwall work above that level, on either side of the slope, and fears what effect the later extraction of the coal will

have on the slope itself. In that case, we think that his second suggestion of resting the crossbars in hitches cut in the rib is far better than resting them on legs, after the manner of double timbering.

The question of supporting the crossbars in hitches in the rib, in any case, depends primarily on the hardness of the coal. If the coal is soft and friable, it will not furnish the needed support to the crossbars and such a method of timbering would then be impracticable. It is also of interest to know the nature of the floor underlying the seam. The question is a practical one and we gladly submit it to the readers of *Coal Age*, in the hope of receiving many good suggestions.

Finding Percentage of Grade Expressed in Degrees and Minutes

No formula for calculating percentage of grade from degree of inclination—Use must be made of table of sines and cosines.

KINDLY explain how a person would go about the work of obtaining a formula that would provide a simple means of calculating the percentage of grade of a slope when its inclination is given in degrees and minutes. I have been unable to find any help from textbooks on this subject. STUDENT.

Patton, Pa.

It is not possible to develop a formula for converting degrees of a circle into a co-ordinate system that would express the corresponding percentage of grade, either in terms of the horizontal distance or measurement taken on the incline. Referring to a table of natural functions, the tangent of the angle of inclination will give the percentage of grade, expressed decimally in terms of the horizontal distance. Likewise, the sine of the angle of inclination will give the percentage of grade, expressed decimally, in terms of measurement on the incline.

For example, a slope having an inclination of 30 deg. has a percentage of grade of 0.577, or 57.7 per cent referred to the horizontal distance. The percentage of the same slope referred to distance measured on the incline is 0.5, or 50 per cent.

Examination Questions Answered

Miscellaneous Examination Questions

(Answered by Request)

QUESTION—*If the airway in a mine is 8 ft. high, 10 ft. wide and 3,600 ft. long, how much will the pressure have to be increased to pass the same quantity of air when the length of the airway has been increased to 7,200 ft.?*

ANSWER—Other conditions remaining unchanged, the pressure will vary with the length of the airway. In this case, the length of the airway being doubled, the pressure must be increased in the same ratio. Therefore, to pass the same quantity of air through an airway of twice the length will require twice the original pressure.

QUESTION—*(a) What are the principal causes of mine fires? (b) What precautions should be taken to avoid them? (c) Explain the method of approaching and fighting mine fires?*

ANSWER—(a) The principal causes of mine fires are the careless use of naked lights, in mines generating gas, or in proximity to combustible material, such as hay, oily waste, or oil-soaked timbers. Fires may result from the ignition of gas feeders, in blasting coal; or the ignition of gas or dust, by the flame of a blowout shot, the sparking of wires or blowing out of a fuse. Again, fire may result from spontaneous combustion taking place in oily waste, or by reason of the heating of fine coal and slack stored in the gob.

(b) Strict rules and regulations must be observed regarding the use of open lights in mines; the blasting of coal and handling of explosives; the storage of waste and other combustible material when not in use in the mine. All electrical installations must be properly made by a competent mine electrician and every precaution taken to prevent the accidental short-circuiting.

(c) In fighting a mine fire, it must be approached only from the intake side. Experienced men must be employed for that purpose and they should be equipped with approved safety lamps. Men working in the mine must be notified and withdrawn at the first indication of danger.

QUESTION—*What is the rubbing surface of an airway 8x12 ft., in section, its length being 6,550 ft.? (b) if the velocity of the air is 350 ft. per min. what is the volume of air in circulation?*

ANSWER—(a) The perimeter of the airway being $2(8 + 12) = 40$ ft. and its length 6,550 ft., the rubbing surface is $6,550 \times 40 = 262,000$ cu.ft. per min.

(b) The velocity of the air current is then $262,000 \div 330 =$ say 794 ft. per min.

QUESTION—*Find the water gage that should be produced by a fan in circulating 105,000 cu.ft. of air per minute in an airway 8x12 ft. in section and 5,000 ft. long, including the return.*

ANSWER—The rubbing surface s and sectional area a of this airway are: $s = 2\ (8 + 12)\ 5,000 = 200,000$ sq.ft and $a = 8 \times 12 = 96$ sq.ft. Then, using the Atkinson coefficient $k = 0.00000002$, we have for the required water gage,

$$w.g. = \frac{k\,s\,q^2}{5.2\,a^3} = \frac{0.00000002 \times 200,000 \times 105,000^2}{5.2 \times 96^3} = 9.6\ in.$$

This is an unusually high gage due to circulating the air a distance of nearly a mile at a velocity of $105,000 \div 96 =$ say 1,090 ft. per min. In practice this circulation would be divided so as to reduce the gage. Ignoring shaft and main airway resistances, if this air was made to travel in two equal splits the gage would be one-eighth of the previous amount, or 1.2 in.

CORRECTION

Attention has been kindly drawn to a typographical error that occurred in the reply to the second question on page 261, of the issue for Feb. 8, where the efficiency in steam-boiler practice is given as "varying from 3 to 7 per cent," instead of 50 to 70 per cent. The fair average evaporation due to burning the 5 lb. of coal, in that question should then be, say $0.60 \times 72 = 43.2$ lb. It may be more or less, depending on numerous factors, but chiefly on the heating value of the coal, type of boiler, manner of firing, etc.

Fear of Future Shortage Causes Hysteria In Northeast, Says I. C. C. Chairman

Personal attention to the fuel situation in northern New York and New England by President Harding, based on daily reports of the Interstate Commerce Commission; application by the Attorney General of New York State for authorization to seize coal on sidetracks on the ground that such cars have lost their interstate status; seizure of two cars of coal by the municipal authorities in Saratoga, N. Y., and advocacy by Mayor John F. Hylan of New York of seizure and control of the mines by the government were some of the developments in the coal situation last week.

Due to several days of low temperature New York City passed through the "worst combination of circumstances" it had seen in thirty years. While heavy ice floes made worse by the cold wave and a northwest gale prevented coal barges being brought across New York Bay and the rivers in anything like normal numbers, there was no real distress reported. Emergency complaints to the State Fuel Administrator's office multiplied rapidly. Several barges containing more than 10,000 tons of domestic sizes were sunk by the heavy ice, and at one time it was asserted by railroad officials that there were 75,000 tons of coal on the New Jersey terminals which could not be moved.

Efforts made to force the administration at Washington to embargo shipments to Canada apparently having failed, the municipal authorities at Saratoga, N. Y., on Feb. 19 seized nine cars of coal on the Delaware & Hudson R.R., releasing seven of the cars later on. The seizure was on the following day characterized as "ill-considered and unwarranted" by General George W. Goethals, State Fuel Administrator, who also said the seizure was made against the advice of Clarence B. Kilmer, district administrator for Saratoga, and representatives of the Federal Fuel Distributor and the Interstate Commerce Commission.

Chairman B. H. Meyer, of the Interstate Commerce Commission, discussed the fuel situation in New York State and New England with President Harding. Mr. Meyer informed the President that after the request of Federal Fuel Distributor Wadleigh for priority orders for coal shipments to districts in New York and New England the Interstate Commerce Commission sent agents into this region who submitted reports that in virtually every instance the shortage had been relieved. Mr. Meyer told the President that in his opinion it was fear of a future shortage if cold weather continued and not a present lack of coal that had created a condition of hysteria and that much of the complaint was due to the unwillingness of consumers in these sections to dilute their anthracite with bituminous coal.

The New York State Legislature passed a resolution by Senator Ferris requesting the State Fuel Administrator to exercise the power conferred upon him by law to take immediate steps to furnish fuel to the people of the state who are at present suffering and in great peril. This action was taken in view of the fact that General Goethals had shown some hesitancy in seizing coal and had sought to obtain co-operation with the federal authorities rather than proceed under the provisions of the New York State statute.

On Feb. 21 Mr. Ferris, in the Senate, and Mr. Bartholomew, in the Assembly, introduced a bill amending the public service commission law by inserting therein a new section prohibiting common carriers without consent of the Public Service Commission from establishing embargoes on shipments of coal or other necessaries of life or refusing to accept shipments of such for transportation.

Carl Sherman, Attorney General of New York State, warned all communities that seizures of coal are "wholly unlawful" except when made under the direction of the State Fuel Administrator. When seizures are so made the price will be fixed by the Fuel Administrator and steps will be taken to replace any coal seized.

Deputy Attorneys General Edward G. Griffin and Francis W. Cullen appeared before the Interstate Commerce Commission in Washington and made application for authorization to seize coal on sidetracks, taking the position that such cars lost their interstate status when blocked in transit. This view was also indorsed by Attorney General Sherman as well as by General Goethals.

Later in the week two cars of anthracite in the Mechanicsville yard of the D. & H. R.R. were diverted to relieve the shortage in that city by direction of District Fuel Administrator Kilmer. Earlier in the day residents of the city threatened to seize the coal passing on cars.

President Harding is being kept informed on the efforts made to relieve the situation in New York and New England by daily reports from the Interstate Commerce Commission. The commission is doing all in its power to meet the situation and stands ready to issue priority or other orders if the facts justify such action.

The New England coast was ice blocked for several days, the ice in some ports being from 15 in. to 2 ft. thick. Coastguard cutters were employed to break the ice and let the coal barges through with their cargoes.

In Connecticut the State Police Department issued a request to the public to use substitutes.

A resolution said to have been offered in behalf of 20,000 miners of the Hudson Coal Co. was sent to Mayor John F. Hylan of New York City asking President Harding to intervene against "the rule-or-ruin tactics of the coal-carrying roads of the country." The Hudson Coal Co., it was charged in the resolution, had not operated its twenty-two collieries more than half time since last September. This was attributed to inability of the D. & H. R.R. to furnish requisite cars as a result of the shopmen's strike.

Mayor Hylan of New York, in a letter written at Palm Beach to Murray Hulbert, acting mayor, and made public Feb. 23, advocated immediate government seizure and operation of all mines.

Keeney Freed; Witnesses Tampered With

The trial of C. Frank Keeney, president of the West Virginia United Mine Workers, charged with being an accessory to murder in the Logan County miners' armed march in the summer of 1921, came to an abrupt end at Berkeley Springs, W. Va., Feb. 23, when Judge Woods dismissed the indictment on motion of the prosecution.

At the opening of court H. D. Allen, prosecuting attorney, asserted that four important witnesses for the state had mysteriously disappeared and he would not attempt to continue the case without them.

Judge Woods indicated that in the circumstances nothing remained for him to do but to grant the motion. T. C. Townsend, of counsel for Keeney, objected, stating that the witnesses in question also were witnesses for the defense and that three of them had come to him a day or two ago asking protection from deputy sheriffs from a "foreign county." They told him, he said, they had been compelled to make statements which were untrue.

Judge Woods ordered the witnesses brought into court. When they entered they were taken to the prosecutor's table and after a brief conference Mr. Allen told the court the men would not discuss the case with him and that it would be useless for him to proceed without them. Judge Woods agreed with him and Keeney was freed. The court ordered that the three witnesses be held for further investigation and that warrants be issued for any persons believed to have intimidated witnesses.

Sentence 47 of Cliftonville Mine Mob

Forty-seven men who were in the mob which burned the tipple at the Cliftonville mine, in West Virginia, near the Pennsylvania state line, last July were convicted or entered pleas of guilty to the indictments brought against them at Wellsburg, W. Va., Feb. 23. Sheriff Duvall and six of the attacking party were killed in the fighting.

Forty-three of the indicted men pleaded guilty to conspiracy and each was sentenced to serve three years in the Moundsville Penitentiary. The Grand Jury indicted 220 men, but only those in custody were caught. Seventy-eight were charged with murder. Four of these went to trial and were found guilty. Each was sentenced to ten years in the penitentiary. Indictments against those who have not been apprehended will stand.

Miners' Union Urges Detailed Probe of Anthracite; Union Disregards Facts, Says Warriner

In response to the recent request of the U. S. Coal Commission for suggestions and recommendations from the miners as to matters and subjects which the commission should investigate, the United Mine Workers of America filed with the commission Feb. 20 the first statement in behalf of the miners in the anthracite industry, the subject covered being "Mining." Additional statements to be filed later will deal with various other subjects connected with the anthracite industry. The first statement is signed by Thomas Kennedy, C. J. Golden and W. J. Brennan, presidents of the three anthracite districts of the miners' union, and Ellis Searles and John Moore, of the committee representing the union before the commission. The statement is as follows:

"We hereby accept your invitation to offer suggestions as to the range of facts that should be known about the anthracite industry and the ways by which they should be found out and made public. We realize that it will take time to get the essential facts, but that without them any pronouncements that might be made about the industry by strangers to it would be quite worthless.

"To show you from our more intimate knowledge of the industry the complicated problems of fact finding that Congress has set you, we present certain tables and estimates as close to the truth as is permitted by the very limited information made public. From these we conclude that the present monopoly organization of anthracite, through overcharges in each branch of the business, adds at least $3.61 per ton, which is immediately discoverable, to the present price the consumer pays, and much more which cannot be exactly estimated.

(1) In mining, an average overcharge, per ton, of	$1.26
(2) In land-owning, an overcharge which we will not attempt to estimate, but which may become the most disturbing factor in the industry in the immediate future.	
(3) In transportation, an average overcharge, per ton of	1.00
(4) In distribution, an average overcharge, per ton, of	1.35
	$3.61

"This sum ranges from $4 and $5 on domestic sizes down to approximately $1 on smaller sizes to produce the average given. It is an overcharge which amounts to a total of $252,700,000 on an annual commercial production of 70,000,000 gross tons. With similar prices, it would amount to $270,750,000 on an annual commercial production of 75,000,000 tons, which is occasionally reached.

"With such estimates before us to establish and confirm our beliefs, we ask the obvious question: 'Are these overcharges inevitable?' Is the business of mining, transporting and distributing anthracite doomed always to be so organized that a few high-cost land lessors or real-estate speculators, a few high-cost collieries, a few railroads which choose to spend their incomes on vindictive labor war, and a few high-cost distributors scattered over the country can always create a situation in which the great bulk of low-cost operators, landowners, transporters and distributors will always be tempted to advance their profits at the expense of everybody else interested in the industry?

"We do not believe it is inevitable or in any way necessary. To get to the bottom of this situation, we are asking you to find the facts which will answer certain fundamental questions implied, but not directly stated, in your suggested topics. We should like you to inform us whether or not your investigation into facts will or will not finally include these questions.

"To connect your nineteen scattered topics with our questions, we have followed the natural division of the industry into: (1) Mining; (2) land-owning; (3) transportation; (4) distribution; (5) the future of the industry.

"*Mining.*—At December, 1922, prices, the mine operators appear to be receiving a net income of approximately $1.48 for every ton of anthracite sold, including steam sizes. If these prices continue throughout 1923 until the expiration of the present agreement, they will make approximately $103,600,000, which is over 30.8 per cent on their capital stock or 41 per cent on what we believe to be the actual cash invested in capital stock. We believe that 22c. per ton will give a 6 per cent return upon the actual investment, and that everything above that is excess profit, taken and insisted upon not only at the expense of the consumer but at the risk of periodically disorganizing the industry.

"To determine the significance of your profit data, we ask you to determine the actual investment in the anthracite mines. This is the only figure which will give a basis for judgment as to excessive returns. We believe that this valuation should be done on the basis of original cost plus added expenditure. This is the only way to determine the amount allowable for deductions for depreciation and depletion. We stand ready to submit argument in favor of this basis of valuation of the coal mines.

"Six companies (the Lehigh Coal & Navigation Co., the Lehigh & Wilkes-Barre Coal Co., the Lehigh Valley Coal Co., the Philadelphia & Reading Coal & Iron Co., the Delaware & Hudson Co., and the Delaware, Lackawanna & Western Coal Co.) reported:

Net Income (All Six)		Surplus (First Four)	
1912	$8,800,000	1912	$10,000,000
1920	$32,000,000	1920	$74,000,000
(An increase of 363 per cent)		(An increase of 739 per cent)	

"If all the coal companies earned the same rate of return and increased their surpluses in the same proportion, the anthracite industry would show:

Total Net Income (Estimated)		Total Surplus (Estimated)	
1912	$13,300,000	1912	$24,000,100
1920	$51,000,000	1920	$192,400,000

"The information on these other companies has never been made public.

"In the face of such figures the miners are tired of the operators' common cry that coal strikes are caused by the lack of ability to pay better wages. There has just been a five months' suspension because of this disagreement over the question of whether the industry could or could not afford better wages and more satisfactory conditions of work. The miners drew on their credit, established laboriously over many years of constant and dangerous work, to support themselves during idleness. We agree with modern industrial engineers that the companies should do the same. There is no justification for the present high prices on the ground that the companies are paying for the expense they went to in their attempt to lower wages. If the companies are to protect themselves against such industrial losses by charging the public high prices, it would be equally just that the miners receive compensation of some sort from the companies for each day of every strike or lockout, and the miners have never asked for that.

"It is very important for the public to know the facts about profits and costs in detail. We know that the amount given as representing the value of the capital stock does not mean that anything like that figure was actually invested in the industry. We know that there are bookkeeping ways of increasing apparent costs and making the industry seem unprofitable. We therefore ask you not only to determine the present value but to establish and insist for all time upon a uniform accounting system similar to the one advocated by the Federal Trade Commission. Unless a satisfactory accounting system is adopted and enforced, the public and the miners will continue to disbelieve the statements of costs and profits which are now given so much publicity. We shall instead remember the report of the Engineers Committee of the U. S. Fuel Administration (1919) which said of the coal industry as a whole: 'depreciation was often put in as a guess. In some cases it was frankly stated that this seemed a good time to charge off improvements, and such were charged to the limit and beyond.' The same report spoke of depletion, which is another way of retiring the capital invested. It said: 'Depletion of lands was also an item which appeared greatly to trouble some of the accountants. While generally under-

stood, many very wild guesses, even up to the market price of the product, were found; also many instances of depletion charges for land operated on royalty or lease and not property of the operator.'

"These findings agree with our own beliefs that there are double charges made upon the industry in every branch, which are ultimately dangerous to its stability. We believe that much is charged to maintenance and repairs which should be charged to capital account. We, therefore, ask you to examine such charges on the industry with a view to eliminating everything which is unnecessary and unwarranted. Until that is done the anthracite-coal industry will not be able to give the efficient public service we believe it should give. We know it is natural under the present system of long-distance ownership that there should be such double charges, a keen desire for great profits, and a resulting indifference to the welfare of the men who are investing their lives in the industry.

"You will find out that this is because the majority of the coal mined is controlled by the railroad companies, which in turn are controlled by large financial interests in New York and Philadelphia, by men who have never seen the inside of a mine, but who attempt to regulate the meals, living and opportunities for schooling of the miners' families by their decisions on wages. It is known that the bankers played a leading part in the 1922 suspension. We ask you to convince yourselves of these facts as we are convinced, by tracing out the ownership of coal from the ground through the processes of mining, transportating and distributing—processes often controlled entirely by one interest which then takes four different profits on every ton.

No Guarantee of Regular Employment and Output

"You will find that neither the present ownership nor the present management has yet been able to guarantee regularity of production and employment to the industry. In spite of the relatively steady work (256 to 272 days out of a possible 308) during the past few years, anthracite is not immune to irregularity. It is known that the coming of the 1922 suspension concealed the fact that there were to have been at least 60 idle days during the summer of 1922. You will find that this is due locally and occasionally to car shortage. The U. S. Department of Labor reported for November, 1922: 'Wilkes-Barre—Inadequate transportation has retarded employment in the mining industry.'

"We believe the possible irregularity of production is due to the apparently limited market for the average amount of anthracite produced. The market might have been widened: (1) If exorbitant freight rates were not charged on anthracite, which discriminated against it in favor of soft coal; (2) if middlemen did not take such a large share of the value of each ton; (3) if the operators and land lessees did not insist upon such large profits.

"We ask you to inform us of any ways by which the market for anthracite can be increased.

"You will find that there has been wastage of coal. There is less of this now than there was formerly, but where managements change, as they still do in the smaller mines, and each new management seeks to cream off what it can, the result is often that much coal may be lost. In certain mines the operators went right after the coal that was closest to the mouth drift, shaft bottom or slope bottom, and removed it without regard to the mining of coal further off. This desire for immediate production with apparently low costs resulted over a period of time in an increased cost of production because of the increased requirements for more timber props, etc. This condition could have been avoided if the mine had been worked with the purpose of getting out all the coal available instead of with the desire to get everything while the getting was good and to sell out as soon as the results of this policy became apparent.

"If it were possible for men to engage in the business of mining coal in order to produce fuel for the country instead of producing profits for a few investors, the amount of waste might be eliminated.

"We therefore urge that, if you limit your attention to the mere facts about the cost of living, wages paid in similar industries, and the superficial showings of the balance sheets, your work will leave the industry quite where you found it. If your work is to be of any use at all in settling the coal question, you must take account of the whole range of claims upon the industry in the form of the various items of costs, wastes and the claims by capital holders—with the purpose of eliminating all exorbitant, unnecessary and consequently disturbing charges. Lack of a complete detailed statement year by year of costs, profits and investment in each branch of the industry has created a situation where the mining, land-owning, transporting and distributing departments of the industry shift the burden of proof for high prices from one to the other in an apparently high-minded desire to show that their hands are clean, their hearts are pure and their earnings low. Lack of itemized knowledge of the costs that enter into each branch is a difficulty we expect you to remove. This ignorance was the fact that led the consumers of anthracite (represented by the legal departments of Massachusetts, New York, etc.) to fear that the small increase (approximately 10c.) caused by the recent anthracite tonnage tax would result in an entirely disproportionate rise in the final price.

"We therefore ask you to discard the division of costs into labor, supplies and other expenses, and to make public in detail how much of the cost of a ton of coal is devoted to: (1) labor, (2) supplies, (3) power, (4) compensation insurance, (5) administration, (6) depletion and depreciation, (7) county and state taxes, (8) royalty.

"We ask that you make public the information you collect so that it may be stated in the following form: (1) Cost per commercial ton (itemized); (2) profit per commercial ton before federal tax; (3) profit per commercial ton after federal tax; (4) proportion of profit to actual investment.

"We recall your promise to give the miners representation in examining the cost figures of the various collieries and companies and again state our belief that this is essential.

"We have no confidence in the figures supplied in the past by the operators to the Department of the Interior or to the Federal Trade Commission, although the latter body made a more critical study of them. Any figures you may now ask for and receive will not differ in our estimation from previous compilations unless we are given the opportunity to know in detail what the figures are, and are given the opportunity to study, analyze and criticize the varying accounting systems used in their preparation."

Warriner Attacks Union Statement

S. D. Warriner, chairman of the General Policies Committee of Anthracite Operators, on Feb. 21 issued a public statement pointing out the weaknesses in the assumptions made by the union representatives as follows:

"The purpose of the published statement of the miners' organization is inexplicable, unless it is to divert attention from the real cause of the coal shortage from which the public is suffering. The present shortage of anthracite is due exclusively to strikes, and strikes in the anthracite industry are at all times unjustifiable, because for over twenty years that industry has been distinguished by a labor board which provides for the adjustment of all disputes by conciliation, with final resort to an umpire. Notwithstanding this, and even since the settlement of the strike in the anthracite field in September, hundreds of thousands of tons of production have been lost by outlaw strikes in violation of agreements.

"The statement that the anthracite producers are overcharging the public $3.61 a ton must, as the miners say, be based on 'very limited information.' It shows a reckless disregard of the facts for the miners' organization, with little or no information in its possession, to pretend to fix such a figure as $3.61 as overcharge.

"The United States Coal Commission is making an elaborate investigation of the cost of production, transportation and distribution of anthracite, and the operators are co-operating with it in furnishing the necessary information as to the costs and profits. Until this information has been compiled and the commission has made its findings, it is absurd for any of the parties in interest to attempt to prejudge the case and mislead the public by any such statement as was published in the morning papers."

L. & N. Ry. Adopts Commission Plan of Car Allotment to Mines

The Louisville & Nashville Ry. has committed itself to the commission plan of car allotment to the mines on its system. This was agreed to at a meeting held in Louisville, Feb. 23, and will become operative March 1.

The acceptance of the commission plan was the result of months of work on the part of the various coal associations in the districts along the system, which held numerous meetings at their own headquarters, Louisville, Cincinnati and Washington. Special committees were drafted from those representing operators in southeastern Kentucky, northeastern Tennessee, the Birmingham district, eastern Kentucky, southern Indiana, western Kentucky and even the small group in the western part of Virginia had its voice in the matter.

A meeting of representatives of the special committees was held in the morning and elected Attorney Van Norman, who represents various coal interests but who had no particular ax to grind, chairman. J. H. Amos, of the Jewett, Bigelow & Brooks interests, Cincinnati, was made secretary. After threshing out the various plans that were proposed it finally was agreed that the commission system that is in use by the Norfolk & Western Ry. comes close to being the most workable if applied to the L. & N. The point whether it should be a three- or a five-man commission was left open.

Through various conferences held by coal shippers and representatives of the large coal-carrying roads operating in southern West Virginia during the latter part of February a uniform system of car allotment and car distribution was worked out, effective March 1, and under the agreement reached in all cases allotment commissions have been established whose members will visit personally the various coal mines and allot each mine the number to which it is entitled under the rules and regulations adopted. The meeting of shippers and officials of the Chesapeake & Ohio was held at Huntington and rules and regulations worked out at a conference there. Similar rules and regulations were worked out at a meeting between about 45 shippers on the Virginian Ry. and officials of that road at a meeting held at Huntington. The conference between Norfolk & Western shippers and officials of that road was held in Washington. J. W. Davin, of Huntington, is chairman of the Chesapeake & Ohio allotment commission of five; W. F. League, of the Virginian commission of three, and the understanding is that John Stewart will retain his position as chairman of the Norfolk & Western allotment commission and that the present commission of two will be enlarged.

Kanawha Operators to Consider Proposals Of Union Scale Committee

Operators from the Kanawha district in West Virginia, meeting at the Chamber of Commerce in Cincinnati on Friday, Feb. 23, elected to meet the United Mine Workers scale committee of that district for the purpose of hearing what proposals they have to make regarding the agreement which must be continued after March 31. To this end they appointed E. O. Dana, of Cincinnati (chairman); O. F. Harris, Cannelton, W. Va.; John Snure, Wheeling; John McKeever, Longacre; W. C. Michel, Plymouth; A. W. Pollock, Ramage; A. W. Fugel, Blakeley, and A. Michire, of Charleston, as their scale committee.

As the Kanawha district stands at present about 65 per cent of the tonnage is being produced on an open-shop basis and 35 per cent under agreement with the miners' union. Of the latter the mines on the Kanawha & Michigan R.R. are organized 100 per cent and about 20 per cent of the production on the Chesapeake & Ohio side of the river is put on wheels by closed-shop miners.

The open-shop production is fathered principally by the Kanawha Operators' Association and these are firm in their resolve to continue the policy. It developed through the meeting that some nine mines would find it impossible to continue production under the scale agreed to at the New York meeting and that they might be forced to stay out if an agreement is entered into with the union. This would cut the C. & O. tonnage to 12 per cent instead of 20. Many angles of the conditions that have to be faced were gone over and the drafting of the scale committee would indicate that further negotiations are in sight—even though Frank Keeney, as the spokesman for the unionists, issued a bombastic statement on Saturday regarding the basis of settlement that the miners intended insisting upon.

Colonel E. O. Dana, who was the chairman of the Cincinnati meeting, said: "It was the consensus of those present that we should meet with the miners at a later day and closer to the time when the existing agreement expires. There will also be further meetings of the operators between now and that time."

Walsh Asks Data on Anthracite Impurities

Under the terms of a resolution introduced by Senator Walsh of Massachusetts Feb. 26 and adopted by the Senate with only brief discussion, the U. S. Bureau of Mines is directed to report to the Senate the results of its studies of anthracite coal in purchases for government use in Washington. Specific reference in the report is asked regarding the extent to which impurities and misgrading have been found in domestic sizes of anthracite; what information the bureau may have as to the extent of impure or misgraded anthracite generally marketed to the public, and whether it is the opinion of the bureau that legislation should be adopted seeking to establish market grades in size and quality of anthracite shipped in interstate commerce.

The preamble recites that there is "general complaint of the marketing to the public of anthracite coal of misgraded sizes and containing a large proportion of impurities."

Senator Walsh's bill to establish standards of anthracite coal in interstate commerce, which he introduced several weeks ago and which had been on the table, was referred to the Committee on Mines and Mining last Friday when reached on the calendar. Senator Walsh attempted to obtain immediate consideration, but Senator Poindexter, declaring that the bill required study and probably would need "considerable amendment," insisted upon a motion that it be referred to the committee, this motion prevailing.

I.C.C. Revokes Service Order 38

Washington, Feb. 27.—In vacating its Service Order 38, the Interstate Commerce Commission practically admits its mistake in having issued this order over the protest of Federal Fuel Distributor Wadleigh. This service order gave a large preferential car supply to the Mountevallo mine in Alabama without charging the cars against the distributive share of the mine. After the order was issued Mr. Wadleigh again objected and requested reconsideration of the order and its annulment. Another indication that Mr. Wadleigh is right in his analysis of the situation was the fact that the mine was unable to load a considerable proportion of the cars which it received during the time the service order was in effect.

Asks Hammond to Combat State Coal Laws

A public utterance by John Hays Hammond as to the inadvisability of coal legislation by the several states has been asked by J. C. Brydon, chairman of the bituminous operators' special committee. The request was made because it is feared that state legislation may change conditions so that the commission's report will be made to Congress on facts obtained before the situation was changed by state legislation.

The bituminous operators' special committee will meet March 8 in the law offices of Henry L. Stimson, 32 Liberty Street, New York City.

Lewis to Study British Coal Situation

John L. Lewis, president of the United Mine Workers of America, was a passenger on board the White Star liner Celtic, which sailed from New York City Feb. 24 for Liverpool. He is going to make a six weeks' survey of the coal situation in England. Mr. Lewis said that he would visit the heads of the mine workers all over the United Kingdom and study production and labor conditions.

Coal Commission Now Likely to Get Funds

Washington, Feb. 27.—Chairman Madden formally announced today on the floor of the House of Representatives that the Appropriations Committee of the House is in full accord with the President's Coal Commission. "We would like very much to have recommended an appropriation of $400,000," he said, "but we realize that there is no law that authorizes us to do it. I believe the facts that may be found by the commission, judging from the work it has done already, would justify the expenditure of a very large sum of money."

The significance of this statement from the chairman of the Committee on Appropriations is that a Senate amendment will be accepted by the conferees on the deficiency bill, which practically assures the ultimate voting of the money.

Decision Rendered in Ohio & Kentucky Ry. vs. Louisville & Nashville R.R.

The Interstate Commerce Commission on Feb. 19, 1923, handed down a decision and order on Docket No. 13602, the Ohio & Kentucky Ry. Co. vs. Louisville & Nashville Railroad Co., involving the division of rates on northbound coal.

The line of the Ohio & Kentucky is wholly within the State of Kentucky and extends from O. & K. Junction to Licking River, 38.43 miles. That portion of the line from Cannel City to Licking River, 12.8 miles, is operated under lease from the Caney Valley R.R. Ohio & Kentucky passenger trains are operated from O. & K. Junction to Jackson, 1.37 miles, under trackage rights with the Louisville & Nashville R.R., hereinafter referred to as defendant. All freight is interchanged with defendant at O. & K. Junction.

The important action taken by the commission in this case is to apply the principle established in the P. & W. V. case, that reasonable divisions established prior to the various general increases in rates made during the past few years, should be increased proportionately as the joint rates were increased in order to take care of the growing burden of operating expense.

In this case (Ohio & Kentucky) the division first established on May 1, 1919, is used as the base, because prior to that time no joint through rates were in effect, the coal originating on the Ohio & Kentucky moving out over the L. & N. through O. & K. Junction on combination rates based upon a proportional rate published by the O. & K. Ry. to O. & K. Junction plus the rate published by the L. & N. from that point to destination.

On May 1, 1919, joint rates were published from O. & K. mines on the basis of 20c. over the rate from O. & K. Junction on the rates from O. & K. Junction on the L. & N. The situation since May 1, 1919, on divisions, as disclosed by the report is as follows:

TO ALL DESTINATIONS NORTH OF THE OHIO RIVER, WEST OF THE BUFFALO-PITTSBURGH LINE AND POINTS IN WESTERN TRUNK LINE TERRITORY

		From O & N Jct. to Three Mile Inclusive			From North of Three Mile to Wilburst			North of Wilburst		
		1	2	3	1	2	3	1	2	3
May	1, 1919	25	...	...	25	...	...	27½	...	...
Aug.	26, 1920 *a*	33⅓	33⅓	...	33⅓	33⅓	...	36⅔	36⅔	...
March	3, 1921 *b*	...	35	...	...	35	...	...	38	...
May	25, 1921 *c*	...	34½	...	...	34½	...	...	37½	...
Oct.	6, 1921 *d*	27	...	...	27	...	...	30⅔	...	...
June	16, 1922 *e*	15	32½	28	27	34⅔	34⅔	30⅔	37½	37½
July	1, 1922 *f*	13½	29½	25	26½	31½	31½	29½	34	34

(*a*) General advance of 33⅓ per cent. (*b*) Advance of 4 per cent. (*c*) Reduction of 1⅓ per cent. (*d*) Reduction of 9 per cent. (*e*) Joint rates on the district basis were established by order of I. C. C. from stations O & K Jct. to Three Mile, inclusive, which meant a reduction of 20c. a ton. Rates from stations north of Three Mile not changed. (*f*) General reduction of 10 per cent.

In column No. 1 above are shown the divisions actually in effect between the O. & K. and L. & N.

In column No. 2 above are shown the divisions that would have been in effect if they had been changed in accordance with the increases and reductions in the joint rates.

In column No. 3 are shown the divisions fixed by the I. C. C. in this case, Docket No. 13602.

The division of 37½c. to Cincinnati is not involved in the case. The divisions to stations on pages 98 and 99 of the effective tariff and to Jeffersonville and New Albany, Ind., are ordered by the I. C. C. to be adjusted on a pro-rata basis to the divisions prescribed above.

It will be noted that the I. C. C. fixed divisions for points north of Three Mile in the same amount as those shown in column 2, but from O. & K. Junction to Three Mile, inclusive, they fixed a lower division than shown in column No. 2. This latter was done because the carriers had partly sustained the burden of proof that they should be lower, most probably because of the establishment of joint rates from the latter stations on the district basis, effective June 16, 1922, which meant a reduction of 20c. per ton on the rate.

The I. C. C. also suggests that passenger fares on the O. & K. should be increased and that the O. & K. should arrange for a reduction in the rental of $500 per month paid to the Caney Valley property. This latter means a return of 3.29 per cent on the value of the Caney Valley as indicated in the report of the Bureau of Valuation of the I. C. C., which that road could not earn as an operating carrier.

Marked Increase in Production in January

Most of the figures thus far received regarding January business conditions, according to the Survey of Current Business prepared in the Bureau of the Census and printed in *Commercial Reports*, show a very large productive activity, with new high records in many cases. "Cotton goods, pig iron, steel ingots, locomotives, zinc, bituminous coal and flooring are among the basic commodities whose January production figures show the largest output since the boom period of 1920. Sales and unfilled orders show the same upward trend, especially in metals and building materials. The large car loadings and seasonally high retail sales, as well as the general depletion of manufacturers' stocks, indicate that the goods produced are quickly passing into consumption."

Arc from Broken Feeder Line Caused Dawson Explosion, Says Coroner's Jury

A derailed car on an outbound trip knocked down haulageway timbers, dropping a feeder power line onto the steel car, striking an arc which ignited coal dust. This is the direct cause assigned by a coroner's jury for the Feb. 8 explosion in No. 1 mine of the Phelps Dodge Corporation at Dawson, N. M. The jury, impaneled by T. L. McKinney, justice of the peace, reached this decision after long hearings following the explosion. The mine, in which 122 men lost their lives and much property damage was done, is now cleared, but extensive repairs underground and at the mouth of the slope must be made.

High Court Reverses Central Coal Verdict

In a brief decision, Feb. 26, the U. S. Supreme Court in effect nullified the Arkansas State law permitting suit in any county of the state by a citizen of the state against a foreign corporation which engages in business within the boundaries of Arkansas. The case at issue was an appeal by the Central Coal & Coke Co., a Missouri corporation with mines in Sebastian County, Ark., from a decision of the Arkansas Supreme Court sustaining a lower state court in a judgment rendered Jacob Ocepek, formerly an employee of the Central company, for personal injuries.

Monongahela Operators and Miners Sign Up

The Monongahela Coal Association and the district officers of the United Mine Workers signed an agreement at Pittsburgh, Pa., Feb. 20, on wages and working conditions for the year beginning April 1 next. The agreement covers about 45 mines in the Morgantown (W. Va.) district, in which about 10,000 miners are employed.

In explaining the wage agreement, John H. Jones, president of the Bertha Coal Co., said that the scale to be in force would be the same as that which at present prevails in the Morgantown field.

U. S. Coal Commission Will Suspend Work March 4 Unless Congress Grants Additional Funds

By Paul Wooton
Washington Correspondent of *Coal Age*

Since there have been too many inconclusive investigations of the coal industry, the President's Coal Commission is prepared to suspend its work on March 4 if Congress does not provide it with the necessary funds to continue its program on the scale outlined. It was announced on Feb. 24 by Chairman Hammond and Commissioner Smith that the commission is unanimous in its conclusion that it would be undesirable to attempt to continue its work even until the funds at its disposal are exhausted. On March 4 the commission will have $85,000 of its appropriation still on hand. This will not carry its investigations to a conclusion.

It is not a foregone conclusion that Congress will not furnish additional funds for the commission's use. No appropriation is carried in the deficiency bill as reported out of the Appropriations Committee of the House on Feb. 22. It is possible to attach the appropriation to that bill on the floor of the House or it may be carried in a Senate amendment. There is every reason to believe that the leadership in Congress is entirely willing that the commission should have its $400,000. It was excluded from the deficiency bill because it would have been subject to a point of order since the legislative authority for the appropriation had not been voted. Chief blame is laid at the door of Chairman Winslow, of the Committee on Interstate and Foreign Commerce, who has insisted on subordinating the legislation desired by the commission to the Cape Cod Canal proposition, alien property legislation and other controverted matters which have prevented consideration of coal legislation, which probably would not have led to protracted discussion. Dr. Smith states that the commission has no evidence whatever of any concerted effort either inside or outside of Congress in opposition to the legislation.

Hammond and Smith Speak Frankly

Both Chairman Hammond and Dr. Smith were entirely frank in expressing their views to the Committee on Appropriations. This is shown by the following verbatim extract from those hearings:

Chairman Madden—What would happen to the investigation if you are confined to your present appropriation?

Dr. Smith—I think the chairman of the commission will bear me out in saying that it is not worth while to continue it, if we do not get this additional appropriation.

Mr. Hammond—It would be a sheer waste of money. It would be like starting to build a dam and only completing one-half of it. It would be foolish. It would be much more economical for us to return the unexpended money to the government. As a matter of fact, we cannot undertake to continue the investigation unless we get the appropriation for which we are asking. We pared it down from $540,000 to the irreducible minimum of $400,000. We do not see how we can cut it down more and have a report worth presenting to Congress.

Chairman Madden—Is the commission unanimous in its request for this appropriation?

Dr. Smith—Yes sir; and also unanimous in the belief that it would not be worth while to continue this investigation after March 4 unless this additional appropriation is allowed, and that we should stop the investigation then and save what we can of the appropriation already made.

Chairman Madden—Is the commission unanimous in the belief that the investigation will result in something worth while, if the additional money is appropriated?

Mr. Hammond—We will guarantee it.

Dr. Smith—I would like to add the fact that the commission believes it had a great deal to do with settling the labor difficulties so that we were assured a month ago that there would be no strike on April 1. As a result, the soft-coal market has been softened very much. In four weeks the average price for bituminous coal has gone down 84c.

Chairman Madden—Do you think the commission contributed to that reduction?

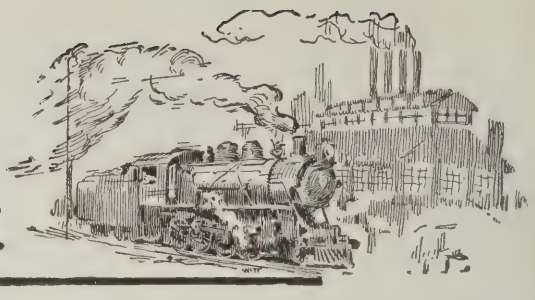
Dr. Smith—We have been blamed for it by some of the coal operators.

Mr. Hammond—I think the operators admit it. Of course, we are abused by some of them because we despoiled them of their profits.

Dr. Smith—Ordinarily that labor situation is not settled until the eve of April 1, if it is settled at all.

An indication that the commission fully expects to obtain its appropriation is had in the announcement of plans for visits to various coal-mining regions. Dr. Devine and Mr. Neill expect to make a first-hand survey of the situation in Oklahoma and Texas mining districts. Chairman Hammond, Governor Marshall and Commissioner Howell already have made their railroad reservations preparatory to a trip to the Alabama fields early in March. Dr. Smith expects to visit a number of the fields nearer to Washington.

Like the Cloaca Maxima, the principal sewer of ancient Rome, the commission is being made a dumping place for all sorts of theories and panaceas. Several of the interests closely concerned with the investigation have addressed communications to the commission which were in fact propaganda. The United Mine Workers have issued two such statements within a week. On the other hand, the commission is a recipient of a great mass of helpful data. Among other things, its attention has been called to a widely held belief that coal operators have not made sufficient use of engineering skill. The record is said to be clear that expenditures for engineering talent and advice represent an insignificant portion of the expense of coal-mine development—very much in contrast with the amount expended for engineers in metal mining. Some engineering methods in the coal industry are held to be entirely inexcusable. Most metal mines, it was pointed out, operate on a 24-hour basis. Most coal mines work only one shift. As a result the great investment in plant and equipment is not being utilized throughout twenty-four hours. Were the mines to be operated for even two shifts, many believe it would have the effect of eliminating more of the high-cost mines and would make for a better labor situation.



Another point being emphasized is that insufficient attention is being given return "cargo" for cars, in direct contrast with the careful consideration being given to return cargo for ships. While the car is a smaller unit and the haul is shorter, which makes the matter of empty transportation relatively less important than in the case of ocean carriers, yet it is held to be a matter of great importance which should concern coal operators, dealers and consumers, as well as the transportation companies. In that connection it also is pointed out that the railroads have been material contributors to overdevelopment in regions containing coal deposits. In their eagerness to obtain tonnage they have frequently disregarded the general economic effect of making possible the opening of new mines when there are too many already.

As this is written it seems certain that the amendments to the Coal Commission Act are lost. While it is possible to put through the appropriation on a Senate amendment, it is not practicable to attempt the handling of other Coal Commission legislation on that basis. The feeling is expressed, however, that penalties are not necessary to assure correct returns on the commission's questionnaires.

Under a bill recently introduced, the State of Utah could take over and operate all Utah coal mines "in time of emergency," selling the coal to the people at cost, thus creating a fund from which mine owners would be reimbursed for all coal removed from their mines at the average price for the preceding year.

Production and the Market

Weekly Review

There is a feeling of easiness in the bituminous coal market. Here and there a better demand exists for various grades and in some instances there have been slight advances in prices, offset, however, by declines at other points. *Coal Age* Index is unchanged from last week, at 288. The corresponding spot price is $3.49.

The severe cold weather general in all sections of the country last week slowed down transportation and sharpened demand. This combination of circumstances also held the market even.

Production of soft coal has dropped to a new level, being now around 10,500,000 net tons per week. Every prospect is for lower tonnages during March.

Price changes were more general in the high-volatile coals than in the low-volatile grades.

There are faint indications of foreign demand for smokeless coals because of the Ruhr situation and the steady advance in Welsh coal prices. These, however, are hardly to be relied upon to support any ambitious program of coal exports. Two vessels, one for Genoa and the other for Rotterdam, have been chartered for early March cargo loading.

While inquiries are being received here regarding shipments of coal to foreign countries, British coal to the amount of more than 32,000 tons was received in New York harbor during the week ended Feb. 24.

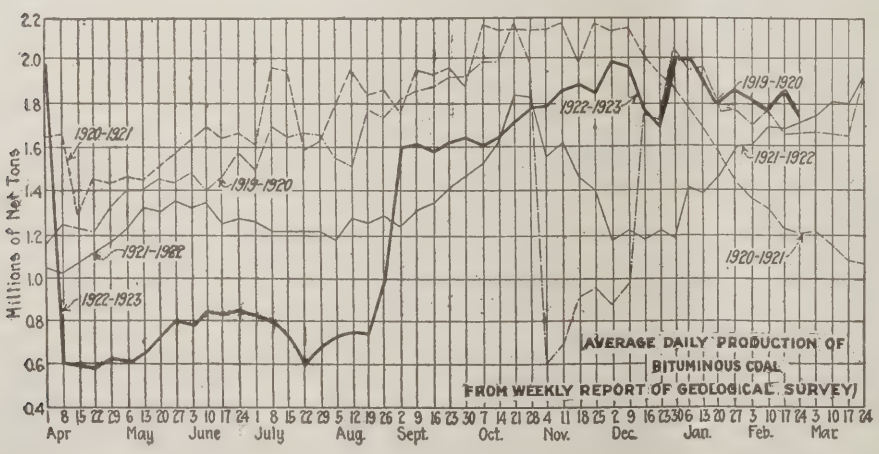
Operators Quote Contract Figures

Operators are freely quoting contract figures and some contracts have been closed at figures ranging from $3.25@$4, with the majority of the tonnage covered at $3.50@$3.60. Consumers are not overanxious to close contracts for their next year's fuel supply and are doing so only when they feel comfortably sure that the spot market is not going lower than their contract figures.

In the Midwest steam coals are sluggish and hard to move while domestic demand was hardly sufficient to take care of the southern Illinois lump and stove sizes. The bottom was kept from dropping out of the domestic situation by the transportation situation.

A peculiar situation existed in the Northwest during the past week. While bituminous coal at the Head-of-the-Lakes was going down in price from 50 to 75c. there was a scarcity of coal around Milwaukee along with snowstorms which hindered rail movement. Duluth dock men, having considerable coal on hand, begun shading prices to avoid an expensive carry-over, excepting lake shipments to bring in coal at a lower figure than the cost of the coal on hand.

At the request of Fuel Distributor Wadleigh, the Navy and the Army has sent tugs to Boston and other New England ports to act as ice breakers to permit the entry of coal barges. Telegraphic advices to Mr. Wadleigh on Feb. 27 indicated that coal barges now can move freely to New England destinations.



Brisk Demand at Birmingham

One of the bright spots in the country is at Birmingham, Ala., where there is a brisk demand for domestic coal due to cold weather. Yards have been entirely cleared of stocks although production is on a basis of around 385,000 net tons per week and car supply ranges from 50 to 60 per cent of requirements.

An ample supply of smokeless coals at the Virginia terminals resulted in a softened market. There was an improvement in coastwise shipments and in the bunker trade. Dumpings, however, were 98,352 net tons less in the week ended Feb. 22 than in the previous week.

The coldest weather of this winter had no appreciable effect on soft coal in the East. Supplies remained sufficient to meet requirements. Heavy ice hampered transportation along the eastern coast from New York to New England and for several days only the larger vessels were able to make deliveries.

The anthracite market is active and domestic sizes moved easily. The smaller operators who a few weeks

(*a*) Subject to revision. (*b*) Revised from last report.

ago reduced their prices from around $13@$14.50 because of the cancellation of orders due to mild weather have gone back to their former prices.

Stocks of anthracite at the Head-of-the-Lakes are now down to 15,000 tons, with the supply going to dealers in small shipments. There were 2,825 cars of bituminous coal and 3,632 cars of anthracite forwarded to New England through the principal gateways over the Hudson River and through Rouses Point during the week ended Feb. 17, as reported by the American Railway Association. This was 4 cars less of anthracite and 636 cars less of bituminous coal than the previous week.

The spot furnace coke market has stiffened. There was a fair volume of buying by consumers while one producing interest has been in the market for coke to apply on its delivery obligations.

"The total soft coal raised during the week ended Feb. 17 is estimated at 10,549,000 net tons, a decline of 239,000 tons from the revised estimates of 10,788,000 for the week preceding," says the U. S. Geological Survey. "Early returns on car loadings in the present week show 39,280 cars loaded on Monday, 30,177 on Tuesday, and 31,392 on Wednesday, thus indicating a rate of production lower than in the week before and a probable total output of from 10,200,000 to 10,400,000 tons."

Midwest Steam Trade Drags

Field and railroad conditions during the past week in the Chicago region were such that steam coals from any territory were sluggish and difficult to move. Domestic demand was barely enough to absorb the best-known and most widely advertised lump and stove sizes from southern Illinois throughout the Chicago and Northwest market region, leaving the others to hunt for buyers. Around St. Louis the cheaper grades of domestic coals from the Standard district were the ones that moved most easily, though the usual steady call for high-grade Mt. Olive lump continued fairly evenly. This movement of domestic sizes brought so much fine coal into transit that screenings everywhere softened. Even Franklin County screenings required pushing at $2.25, the lowest listed price. Association operators held to that minimum as closely as possible, but it was a hard struggle

* Net tons, f.o.b. mines. † Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 288, Week of Feb. 26, 1923. Average spot price for same period, $3.49. This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions each of slack, prepared tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

in the face of Williamson and Saline County competition at $2.

The only thing that kept the bottom from dropping out of even the domestic market was the transportation situation. Congestion at the Toledo, Louisville and Cincinnati gateways held back a good deal of Eastern coal that eventually will reach the Chicago district, thus throwing the market open to Illinois mines. Car supply there permitted not to exceed three days' running time in most southern Illinois mines and only four days in central Illinois. Standard district and Mt. Olive mines east and northeast of St. Louis were lucky to get as much as 2½ days.

Louisville Feels Blockade Effects

The railroad congestion around Louisville, which is making itself felt throughout the whole Middle West, is laid largely to the Kentucky & Indiana Terminal R.R. The inability of that carrier to clear its connections with both Northern and Eastern lines piled up loads back along the routes to the mines and prevented empties from returning to the fields so that the Louisville & Nashville embargoed Louisville early in the week. A good deal of this confusion was clearing along toward the end of the week, but it is expected that several days will elapse before coal can get into good flow again.

Demand general throughout Kentucky is poor. The cold weather of a week ago has softened and with it prices have grown limber again on practically every kind of coal, in spite of the rail congestion. Domestic demand was keen for a short while but nothing could be sold that had not left the mines. Dealers took enough to save transit domestic coal from distress and steam consumers bought steadily if sparingly.

Some of the blame for the slowness of movement off the docks is laid to Illinois and Indiana competition. Southern Illinois coal can be laid down in southern Minnesota and the eastern end of the Dakotas for $8.75@$9. It costs $11.15 at present freight rates, dock men say, to deliver Eastern coal from the docks to the same markets. Hence the strong efforts of the dock interests just now to push their case before the Interstate Commerce Commission for an equalization of rates inland from the Lakes.

Kansas Steam in Some Demand

The fact that dealers in Kansas City and the surrounding territory are still overstocked with coal has shortened the market for domestic sizes, further reduced the production at mines and thus cut down steam coal supply to a point where the standard level of $2.50 shows signs of rising to $2.75. The rise in fuel oil prices is making a railroad or two begin to eye coal with respect once more, coal salesmanagers say. Inquiries are coming in from that source.

Mines in Utah are working a little more than half time and operators are easily marketing all the lump production. Small sizes, however, are sluggish and price cutting has begun. Though domestic sizes move out readily, operators are carefully watching the credit of dealers and consumers in farming communities where financial conditions are not good. Car supply is adequate. There is no labor trouble in the state worthy of the name.

In Colorado car supply is sufficient to keep work time at the mines so high that the market is steadily flooded again with both bituminous and lignite fuels. Two days a week running time more than fills the requirements. Canon City and Walsenburg lump sells for $6 and nut for $5.50. Trinidad lump is quoted at $5.50; nut, $5, and mine-run, $4.50 Lignite lump moves slowly at $3@$3.50.

Ohio Retailers Seek Larger Shipments

With cold weather and car supply poorer Ohio retail dealers are in the market for larger shipments and steam-coal consumers are buying better. On the whole the tendency is upward. Retail stocks around Columbus are exhausted in many instances. Shipments ordered a month or so back have not yet arrived and dealers are not anxious to buy more coal, fearing the shipments will arrive at about the same time. Public institutions, schools and hospitals are in the market for additional stocks and utilities and railroads are buying heavily.

The Cincinnati market has been stabilized by embargoes to the North and bad car supply. The Louisville & Nashville embargo against deliveries to the lines North still holds good. The Grand Rapids & Indiana at Richmond, Ind., is still tight and the Big Four is in bad shape. The jam on the B. & O. is due to the congestion that does not seem breakable at Toledo. The Chesapeake & Ohio is in bad shape because of the lowered supply of empties to the mines.

Output of eastern Ohio mines during the week ended Feb. 17 was 309,000 tons, an increase of 21,000 tons over the preceding week. The mines are unable to work more than 35 to 40 per cent of capacity because of car shortage.

Retail dealers in Cleveland are in the market for lump sizes. They have considerable difficulty in procuring smokeless fuel from West Virginia and eastern Kentucky and anthracite is particularly scarce. The delivered prices for Pocahontas is about $14, and for anthracite from $18 to $19.

Receipts of bituminous coal at Cleveland during the week ended Feb. 17 were 2,733 cars, an increase of 88 cars over the preceding week. Of this tonnage 2,103 cars were consigned to industries and 630 cars to retail yards. Average weekly receipts during the first quarter of 1923 up to Feb. 17 were 2,861 cars per week, as compared with 2,345 cars per week during the last quarter of 1922.

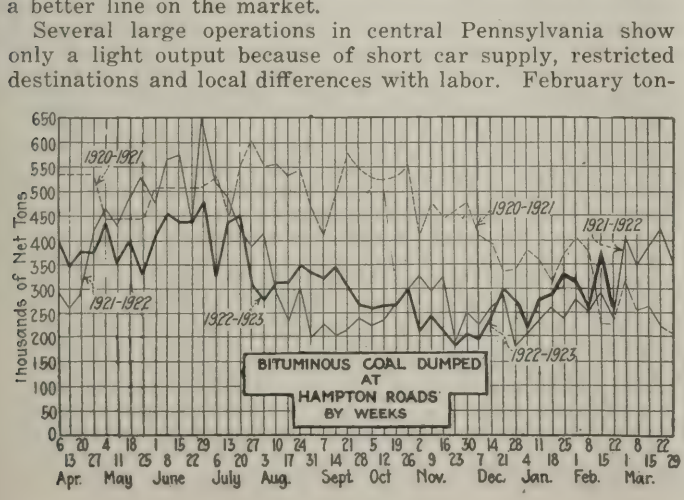
In West Virginia as a whole the car supply is not over 30 per cent. In some sections railroad fuel mines are

obtaining the bulk of the supply. Though not so many cars are being ordered since market conditions and lower prices have eliminated many small mines from the market, companies still loading and shipping are not able to obtain enough cars to take care of orders.

Cars Scarce in Central Pennsylvania

In the Pittsburgh and central Pennsylvania districts car shortage is being seriously felt. In the Pittsburgh region there is little demand in the open market and the cold weather seems to have had little effect upon demand for lump coal. The operators in central Pennsylvania also are suffering because of poor car supply, which is about 20 per cent on both the Pennsylvania and New York Central railroads.

Operators along the New York Central are able to get on an average 25c. per ton more for their coal than those on other roads because of their ability to make shipments into New England.



Steam Receipts Light at Boston

Receipts of bituminous steam grades in Boston have continued extremely light. Embargoes have continued in effect against the Hudson River gateways, especially from connecting lines, and by the water route also transportation has been seriously delayed. A long period of steady cold has caused ice to form in many of the small harbors and particularly on the shoals back of Cape Cod. Barges and certain of the steamers have been held up for days at a time, and even the approaches to the Cape Cod Canal have been so blocked with ice that few boats have come through during the past week. In consequence there has been a mild shortage of bituminous coal to meet current requirements. There has been more or less borrowing on that account, and at the rehandling wharves for inland delivery there has been a sufficient shortage of cars to advance spot prices to the high mark of several weeks ago. At the same time certain of the large factors have based their quotations on the market at Hampton Roads and in such cases the price level has not been above $9.50 per gross ton on cars.

There have been instances where Navy acceptable Pocahontas and New River have been sold quietly at close to $6 per gross ton f.o.b. vessel, but the average probably would be around $6.25. This nets better than $3.50 per gross ton at the mines, and the trade is much interested to see whether during March spot quotations will go lower.

Meanwhile this territory is being diligently canvassed for next season's business. So far we have heard no prices beyond those quoted by one or two operators for April coal but it is quite likely there will be developments in this direction during the next fortnight. Large consumers here are by no means eager to make contracts; there have even been buyers who have cancelled purchases made in December, for the reason that they have comfortable reserves for the present and are looking for lower prices when next they enter the market. Oil has made such inroads with some of the mills that together with water power, which soon must be reckoned with, buyers of this kind feel they can afford to wait developments on coal until they can get a better line on the market.

Several large operations in central Pennsylvania show only a light output because of short car supply, restricted destinations and local differences with labor. February tonnage was very light with most producers, and in spite of the shortage of anthracite, which has perhaps been more acute in New England than at any time thus far, there has been no urgent demand for bituminous coal even by routes that are open.

Anthracite

Demand for the anthracite domestic coals continues strong. The New York market was seriously affected by heavy ice in New York Bay and adjacent rivers and more than 10,000 tons of coal was lost through barges being sunk.

Weather conditions at Baltimore affected the anthracite business. Demand increased and the receipts were picked up as quickly as they arrived.

"The production of anthracite in the week ended Feb. 17 declined to 1,828,000 net tons, including mine fuel, local sales and dredge and washery output," says the Geological Survey. "Save for the holiday weeks (Thanksgiving, Christmas and New Year's); this is the first time since mid-November that the weekly production has fallen below 2,000,000 tons. Labor troubles and transportation disability on account of bad weather were causes of the decline and make it impossible to forecast the present week's output."

How the Coal Fields Are Working

Percentages of full-time operation of bituminous coal mines, by fields, as reported by the U. S. Geological Survey in Table V of the Weekly Report.

	Jan. 1 to April 1, 1922 Inclusive	Sept. 5 to Dec. 30, 1922 Inclusive	Jan. 1 to Feb. 10, 1923 Inclusive	Week Ended Feb. 10, 1923

Foreign Market And Export News

Demand for British Coal for Export Strong; Production Slightly Lower

Production of British coal for the week ended Feb. 10 was 5,567,000 tons, says a cable to *Coal Age*. This was 34,000 tons below the previous week's production and the smallest output for any week this year.

There is a strong demand in the South Wales market which has resulted in stronger prices for some coals.

Inquiries for coal for export are heavy. Germany is looking for all classes of fuel, especially cooking coals and coke. Italy, France and Belgium are reported as heavy buyers.

The German pressure on the Newcastle and Hull markets is excessive, and in response to urgent inquiries and offers to pay in sterling very large sales have been effected alike for prompt and forward shipment. While these sales cover every class of coal, they consist mostly of Durham coking unscreened and steam smalls. In some cases the German industrialists are sending their own boats across the North Sea.

The greatly increased export demand for foundry and furnace cokes sent these brands well up, and it was accompanied by a great improvement, from home sources due to the better outlook in the iron trade. France and Belgium are in need of prompt supplies, and have sent numerous inquiries into the market for industrial fuels, including coke. Italy and the Continental railway and gas works are coming forward with their requirements. The output is large, but is not large enough to meet the demand.

The Ruhr crisis is responsible for increased exports to France and Italy. Exports to Italy are on a higher level than for some time. From forty to fifty steamers are waiting for loadings at the various ports. Within the last month 85,000 tons of coal has been sold to Germany. There is an appreciable quantity of Welsh coal going to India and Egypt.

Stinnes has been soliciting Welsh coal, but has declined offers because of the high prices asked. The north of England market is firm.

French Mines Production Increasing

Production is rapidly increasing in the mines of the Nord and Pas de Calais as is shown by the following tabulation in metric tons:

	Coal	Coke	Briquets
In 1913	29,618,997	2,445,050	1,802,286
In 1921	13,554,028	387,245	1,042,928
In 1922	15,379,566	539,889	1,406,940

That the work of reconstruction is going on rapidly in the devastated collieries is indicated by the following comparative figures showing production in January and December of last year:

PRODUCTION IN DEVASTATED MINES OF THE DEPARTMENT OF PAS DE CALAIS

(In Metric Tons)

	Jan., 1922	Dec., 1922
Coal	227.578	354.584
Coke	0	3.035
Briquets	29.940	25.162

PRODUCTION IN DEVASTATED MINES OF THE DEPARTMENT OF DU NORD

(In Metric Tons)

	Jan., 1922	Dec., 1922
Coal	353.148	379.652
Coke	5.988	27.449
Briquets	84.871	92.825

Hampton Roads Movement Brisk

Movement at Hampton Roads has been brisk, the holiday intervening, however, to cut down the volume. Coastwise shipments have shown a decided improvement and the bunker trade also has taken the upgrade.

The tone of the market grew firmer, with prices apparently halted in their downward trend. Shippers look forward to an early entry into the export field if conditions continue to improve.

Movement of coal to port increased, some improvement in the car situation being noted. The effect of the recent storm in delaying shipping and holding back movement was being eliminated and piers were making up the time lost in this manner. The outlook was brighter than for several weeks.

American Gas Coal for Germany

Firms in Hamburg, Germany, are reported to have purchased several cargoes of American gas coal and inquiries concerning further deliveries from the United States are said to have increased as a result of advancing prices for British coal.

It was also said that English coal firms are negotiating for the lease of dock space at Hamburg in order to lay in large stocks of bunker coal.

Official German statistics made public show that German reparations coal amounting to 1,587,026 tons have been exported from France and Belgium in fifty-nine specific instances during the last two years. It is stated that at least twenty-three offers of this coal were made in neutral countries, and even in Germany. In fifteen of these offers some 200,000 tons, besides 1,042 carloads, were tendered. In at least one instance, according to the statement, the coal was advertised through the newspapers in a neutral country.

News Items From Field and Trade

ALABAMA

The Scott & Jones Cahaba Red Ash Coal Co. has been incorporated in Birmingham with a capital stock of $5,000. W. A. Scott, B. F. Jones and D. H. Jones are incorporators of the new company.

ILLINOIS

Illinois coal operators on Feb. 20 conferred in Chicago with Henry L. Stimson and Goldthwaite Dorr, attorneys for the bituminous operators before the United State Coal Commission. They reviewed the situation as it effects operators through the Commission. Mr. Stimson and Mr. Dorr had met the operators of Ohio the previous day. From Chicago they made a short trip into Midwestern coal fields with George B. Harrington, intending to return to Washington by the 24th.

James G. Monohan, of Chicago, has been appointed manager of the Peabody Coal Co. interests in Springfield. He succeeds the late Alfred G. Halle. Mr. Monohan formerly managed the Peabody interests at Buffalo and for several years was attached to the Chicago office.

A new effort is on foot in the Illinois Legislature **to enact a bill taxing coal production** at the rate of 8c. a ton. At two previous sessions of the Legislature similar tonnage tax bills have been defeated, both operators and miners uniting against them on the ground that they are discriminatory, since they covered only one industry. The bill filed this year was introduced by Representative G. J. Johnson, of Ford County, a region which produces no coal.

A new mine is being located near old Lake Creek, three miles southeast of Johnston City, by the **St. Louis Chemical Co.** A switch is being laid to the site of the new mine. This is the first of three new mines which will be located east of Johnston City.

The Byproducts Coke Corporation, of Chicago, reports net earnings of $255,152 for 1922, against a net operating loss of $1,295,235 in 1921.

Gunplay and murder were described as **daily occurrences in the coal field towns of southern Illinois** by Representative Myers of Franklin County in a speech to a committee of the Illinois Legislature Feb. 21. Mr. Myers was speaking for his bill to regulate the sale and carrying of one-hand guns. "Down where I come from," he told the committee, "murders are so frequent that the local papers pay no more attention to them than they do to weddings."

The fate of the state police bill is doubtful on the floor of the Illinois House. The bill has been reported out of the Military Affairs Committee but is encountering stiff labor resistance.

E. P. Stewart has joined the engineering staff of Allen & Garcia of Chicago and will specialize in the design and construction of coal washeries for that company. Mr. Stewart has been with Roberts & Schaefer, of Chicago.

Forty-nine mines in southern Illinois on five railroads serving that district **have worked on an average two days a week since the miners' strike,** according to figures issued by the Coal Operators' Association of the Fifth and Ninth Districts of Illinois. The statement is made that the loss in working time is due mainly to failure of railroads to supply cars. From Sept. 4 to Jan. 27 twenty-one mines on the Illinois Central worked 38.55 per cent of the time, lost 51.09 per cent of the time on account of no cars and 10.36 per cent due to other causes. Mines on the Louisville & Nashville, Baltimore & Ohio, Mobile & Ohio and Southern railroads showed about the same general averages.

Because of the congested traffic conditions in coal movements through the Duquoin yards, the **Illinois Central R.R.** is making preparations **to construct a cut-off** which will connect the Eldorado branch with the main line and the St. Louis line direct, eliminating the hauling of coal from Franklin County through the Duquoin yards. Company engineers have already surveyed the proposed cut-off and it is expected that work will be started on the job soon.

Indications are that **large coke ovens may be installed** at Zeigler soon under the ownership of the newly formed **Zeigler Coal & Coke Co.** of that town. At the time the new concern incorporated it was announced that only a new mine was to be opened by the company, but later reports are that 1,600 acres of additional land has been obtained by the company for the purpose of erecting large coke ovens. The stockholders of the new company, E. A. Bronson, Frank M. Wakefield and William J. Warr, are all closely connected with Joseph Leiter, now of Chicago, whose Zeigler properties are operated under a long lease by Bell & Zoller.

Damage which amounted to more than $4,000 was done recently to the tipple and shaker screens of the **Western United Gas Coal Co.** mine at Murphysboro. A Missouri Pacific switch engine was switching the mine when **cars broke loose from the engine and crashed into the tipple,** making extensive repairs necessary. The work of repairing the broken and damaged parts of the tipple has been started by the railroad but will require several weeks to complete. The mine was formerly known as the "Gus Blair" mine.

Practically the entire jury has been chosen for the second trial at Marion, Ill., of men indicted for playing leading parts in the **Herrin massacre** of June 22. The majority of the men already seated are farmers, but at least one is a member of the United Mine Workers of America and has been paying into the union defense fund. However, this man declares he can pass impartial judgment upon the case and sees no reason why he cannot go back to work as a union miner in case the jury were to vote unanimously for conviction. No date has yet been set for the opening arguments, but they are expected to start within a few days.

INDIANA

Fire of unknown origin recently did $20,000 damage to the mine tipple of the old Freeman mine at Bicknell, now known as the Howe-Coulter Mine No. 2. Thirteen men who were at the bottom of the mine at the time of the fire escaped uninjured. The plant employs about 300 miners. Firemen from Bicknell saved the engine house and equipment. The principal stockholders in the company are William Howe, John Coulter and Robert McCleavy, all of Chicago, and the corporation was recently reorganized. The mine was formerly operated by the Tecumseh Coal Co. and produces Fifth Vein coal.

Articles of incorporation have been filed with the Secretary of State for the **Burr Coal Mining Co.,** an organization composed of Sullivan capitalists. The company is incorporated for $50,000 and has purchased the Black Comet Mine, in Sullivan County. Heber Stevens, Frank Bolt, Harry C. Boothe and others are interested in the company. The officers of the company will be located in Sullivan. The Black Comet property is east of the city and always has been regarded as one of the best of the small mines in that field. Many improvements have been planned and the mine will be enlarged and modernized.

The H. & K. Coal Sales Co. has been organized at Elkhart, with a capital stock of $15,000 for the purpose of doing a wholesale and retail coal business. The organizers are Robert R. Haggerty, Harry F. Kitchell and Ethel F. Arnold.

The **washhouse at the Dixie Bee mine,** near Pimento, was **destroyed by fire** recently, the miners losing practically all the clothing they had worn to the mine that day. It is believed a thief robbed the washhouse and set fire to it to escape detection of the theft.

KENTUCKY

W. F. Bradshaw, coal operator, banker, insurance man, and president of the Tobacco pool of western Kentucky, may be a candidate for Governor of the state, according to press reports.

P. Wooldridge, of Pewee Valley; C. F. Wooldridge, of Louisville, and others have incorporated the **Falls Branch Coal Co.,** at Louisville, Ky., with a capital of $70,000.

The Ajax Coal Co., of Bulan, Ky., is planning the construction of a coal bin at a cost of $10,000, which is to be modern in every respect.

The mines of the **Consolidation Coal Co.** at Jenkins were able to resume shipment of coal during the latter part of February after being **out of commission for several days owing to a landslide** which buried the tracks of the Sandy Valley & Elkhorn R.R. to a depth of 30 ft. for about 800 ft.

Activities of the Good Roads Committee of the Northeast Kentucky Association have resulted in assurances by the State Highway Commission of Kentucky that a **hard-surface highway will be constructed through the northeastern Kentucky region** and that work will be started without delay. This will provide increased transportation facilities and afford a short-route highway linking the entire South with the territory north of the Ohio River.

With a capital of $15,000, the **Kentucky Coal Sales Co.,** Williamsburg, has been chartered by B. F. Sheely, T. J. Roberts and A. M. Ellison.

The Kentucky Block Coal Co., of Paducah, capital $100,000, **has been chartered by W. F. Bradshaw, H. L. Richardson and C. F. Richardson.** The interests recently took over the two mines of the Coil Coal Co., Madisonville. The Richardsons are active in the management of the big West Kentucky Coal Co., one of the largest in western Kentucky, which operates a fleet of river boats and eleven tipple mines. Bradshaw is a capitalist, tobacco and insurance man.

The Kentucky Co-operative Coal Co., Lexington, has been chartered with a capital of $30,000, by C. C. Perry, of Quicksand, and C. R. Taylor and E. C. Brown, of Lexington.

Utility consumption of coal at Louisville may be reduced materially if plans now under development are completed for **a big hydro power plant at the Ohio Falls, Louisville,** this plant to be supplemented during low-water periods with current from the plant of the Louisville Gas & Electric Co., a Byllesby organization. The city and the company have been fighting to obtain first rights to the water power, the city intervening when it discovered that the company had plans of utilizing the river, no one else having ever before considered the plan as feasible.

Articles of incorporation have been filed at Lexington for the **Ace Coal Co.,** capital $25,000, T. F. McConnell, R. J. Raymond, Lexington, and A. B. Ewen, Whitesburg. The company plans mine operation in Letcher County.

Operators of the state met in Louisville on Feb. 9 with officials of the Louisville & Nashville R.R. in connection with a **new plan for rerating coal mine capacities,** so that some mines will not be getting a larger percentage of cars than they are entitled to. Not much was accomplished at this meeting, due to the fact that the Harlan and Hazard operators were not ready, and didn't have necessary figures available. Western Kentucky operators and those of the Southern Appalachian and Alabama districts fed by the L. & N. were represented. Another meeting was to be held late in February, at which figures were to be compiled and placed in shape for presentation before the Interstate Commerce Commission.

MINNESOTA

An incorrect report from Washington suggests that the hearing before the Interstate Commerce Commission on the complaint of the dock interests will bring a claim on behalf of the dock trade for increasing the rate on competing all-rail coal which comes into the Twin Cities. The complaint sets forth that the commission has established a tariff of $1.82 for the 150-mile haul from the docks to the Twin Cities, which the railroads must charge, and that the roads have voluntarily made a rate of $3.42 for all-rail coal hauled a distance of 642 miles. The complaint sets forth that the difference in the two sets of rates is discriminatory to the dock business and asks to have the discrimination removed. It leaves the method of correction with the commission, and does not suggest anything.

A conference of coal dealers was held in Minneapolis Feb. 13 to consider **the bill for licensing coal dealers** proposed by Fuel Commissioner Ivan Bowen. Mr. Bowen outlined his proposition and there was considerable discussion upon it. Resolutions were passed that there should be no regulation of the coal business undertaken until such time as it is shown to be necessary by the state; that it is not possible for the state to regulate the coal business; and that no regulation should be attempted until the federal coal commission has reported, so that the state proposition may be in harmony therewith.

MISSOURI

T. T. Brewster, president of the St. Louis & O'Fallon Coal Co., St. Louis, attended the sessions of the New York section of the American Institute of Mining and Metallurgical Engineers held in New York City last week.

Fire at the mine of the Blackfoot Coal Co., near Columbia, did considerable damage, the building containing the fan and the motor being destroyed. It made it necessary to stop operations and threw a large number of miners out of work. The plant was working at capacity at the time of the fire because of the sudden cold spell that had come up in Missouri just at the time.

Charles H. Swift, of Lafayette County, formerly surveyor for the Western Coal & Mining Co. and formerly with the engineering department of the City of Colorado Springs, Colo., has been appointed county highway engineer for Saline County, with headquarters in Marshall.

Articles of incorporation have been filed in the office of Secretary of State Charles U. Becker by the **D-H Coal Co.**, Kansas City; capital, $250,000 and 2,500 shares no par value. Incorporators, J. W. Alder, H. A. Fowler, J. E. Yount, T. N. Kingsley, L. S. Harper and F. C. D. Dobson.

Everton and Ash Grove capitalists have formed an organization for the development of the coal resources in that section of Dade County. The development will be a resumption of operations that were carried on some years ago when the Frisco R.R. was built from Springfield to Ft. Scott. At that time a good grade of coal was mined through shallow mining on the right of way just east of Everton.

Contests under the auspices of the Missouri Mine Safety Association will be held at Jacksonville, Huntsville, Higbee and Moberly in keeping with a resumption of the program of rescue work by this association, after a year of inactivity. Suspension of the work was due to the cessation of mining operations all over the country. Notices that these educational meetings are to be held all over Missouri are being sent out by President H. J. Pierce and Secretary George Hepple. Representatives of the Bureau of Mines are now in Missouri and plans for an itinerary have been made out. The co-operation of operators and miners is asked in the campaign in Missouri and all mines are urged to send teams to the cities in which the contests will be held.

NEW YORK

Sixty families in Sidney without coal called a mass meeting Feb. 21 and **seized a carload of coal passing over the Delaware & Hudson R.R.** destined for Lawrence, Mass. When informed of the acuteness of the situation, officials of the road diverted two cars to Sidney, one consigned to Albany and one to Bloomingdale. These and another car were placed in Sidney yards before nightfall. At the meeting a resolution was passed empowering the Village Board and Board of Health to seize coal cars passing through Sidney, if additional cars were not placed without delay.

Railroads would be prohibited from establishing embargoes on shipments of coal or other necessities of life or from refusing to receive such shipments for transportation by the provisions of a bill introduced in the Legislature Feb. 21 by Senator Ferris of Ticonderoga. The measure provides a new section for the Public Service Commission law. Senator Ferris has been active for the last few weeks in endeavoring to provide relief for counties without coal throughout the northern part of the state.

Charles S. Allen, formerly secretary of the Wholesale Coal Trade Association of New York City and more recently acting as secretary of the Tonnage Debtors' and Creditors' Committee of the new Tidewater Coal Exchange, has joined the sales force of **Cory Mann George Corporation.** In addition to the duties of the new connection Mr. Allen will continue to handle the settlements of the Debtors' and Creditors' Committee until that matter is closed.

During January the **New York Central Lines** had **66,021 cars loaded with bituminous coal on the lines of its system**, exceeding the loading of that month one year ago by 53 per cent, the excess of January, 1923, over 1922 being 23,048 carloads. There were 49,607 cars loaded with that class of coal in January, 1922. January coal loadings were greater than the loadings for any January since loading records have been kept. The figures as to coal do not include cars of coal received from connecting carriers, which would bring total coal business to a much higher figure.

The Girtanner Engineering Corporation, now a subsidiary of the American Brake Shoe & Foundry Co., will enlarge its activities of manufacturing and installing standardized steam ash and soot removal systems and other boiler house equipment. Offices have been removed to 30 Church Street, New York City, and agencies are to be established in all of the leading cities.

J. D. Monie, vice-president in charge of operations of the Titan Fuel Co., with office at Johnstown, Pa., **will be located at the New York office of the company**, No. 42 Broadway, for a couple of months beginning March 1.

F. R. Walters, formerly with the Alden Coal Co., has joined the forces of the **Majestic Coal Co.**, of 120 Broadway, New York City. He will look after the trade on Long Island and Staten Island. The Majestic Coal Co. has opened an office at Somerset, Pa., with E. J. Frauenheim, Jr., in charge.

NORTH DAKOTA

Representatives of the **Canadian government have been conducting tests of lignite** at Grand Forks with a representative of the United States Government. The Canadian lignite is being tested to determine whether it may be used with the same result as the North Dakota lignite.

OHIO

The American Export & Inland Coal Co., Cincinnati, has been chartered with an authorized capital of $100,000 to mine and sell coal. The incorporators are E. F. Heasley, Stuart R. Ducker, M. Wellman, R. Johnson and Arthur W. Gordon.

The Merrimac Fuel Co., Cincinnati, has been chartered by H. E. Joseph, W. J. Quinn, Ray E. Manley, Mary Barrett and Fanny Sachs, with a capital of $50,000 to deal in coal and coal lands.

The Slater Coal & Supply Co., Lorain, has been chartered by George L. Slater, F. J. McFadden, D. A. Cook, S. S. McFadden and Mayme J. Ambrozio, with a capital of $50,000 to deal in coal.

The Burns Coal Co., of Columbus, recently chartered with an authorized capital of $100,000, will take over three additional retail yards in Columbus about April 1, making a chain of four yards. All of the yards will be equipped with modern machinery for loading and unloading. Edward C. Sharfnaker is president and general manager.

Lee Hall, who has been president of the Ohio division of the United Mine Workers of America, was re-elected to that position during the annual convention held in Columbus. The convention also went on record as favoring an old age pension law. **William Roy** was re-elected vice-president and **G. W. Savage**, secretary-treasurer.

The American Export & Inland Coal Co. has been incorporated under the Ohio laws with $100,000 capitalization in the place of the American Export & Inland Corporation, a West Virginia company. Ernest Heasley continues as president, with H. H. Randolph, of Williamson, W. Va., as treasurer, and L. N. Birk, of East Bernstadt, Ky., as secretary. The former company is the one that figured largely in the Ford deal that caused so much comment in September. The new company will represent some seventeen mines in the Big Sandy district as their direct mine representatives. Most of them were involved in subsequent happenings that tied up some of the payments for the coal that was shipped.

PENNSYLVANIA

The Lehigh Coal & Navigation Co. reports for the year ended Dec. 31, 1922, a **decrease in both gross and net earnings**, as compared with the year previous. The statement showed revenues of $18,786,431, against $22,801,906 in 1921, and net revenue after depreciation and depletion of $3,788,207, against $5,394,224. After allowing for other deductions there was a net income of $1,587,024, equal to $2.71 a share on the $29,243,400 capital stock of $50 par value. This compares with a net of $3,033,764, or $5.20 a share, in 1921.

Representative Thomas F. O'Boyle, of Lackawanna, it is announced, is having a bill prepared for introduction into the State Legislature **to compel coal companies to sell coal to the general public in the municipality in which the mining is being done.**

The United Mine Workers of America will try to have the present anthracite miners' **certificate law extended to the bituminous mining fields.** This action was decided on at a recent meeting of the anthracite tri-district board held in Wilkes-Barre. The board also decided to fight for the repeal of the anthracite tax law recently upheld by the U. S. Supreme Court.

On Feb. 1 American railroads were **awaiting delivery of new rolling stock estimated to cost about $325,000,000**, according to reports filed by the carriers with the American Railway Association at Washington, Feb. 21. On Feb. 1 unfilled orders totaled 91,354 cars and 1,507 locomotives, of which 23,022 cars and 62 locomotives were ordered during January. The equipment under order was classified as follows: Coal cars, 37,476; box cars, 43,211; refrigerator cars, 6,402; freight locomotives, 1,022; passenger locomotives, 362, and switching engines, 123.

The fifth anthracite district in 1922 produced 866,450 tons, while in 1921 output was 2,056,299 tons, a decrease of 1,189,849 tons, says the report of S. J. Phillips, mine inspector. This was due to the strike. There are 12 collieries and 30 mines in the district, while the mines in operation, the report says, number 24. Of the tonnage produced 827,662 tons were shipped to market, the balance being sold to the local trade and used for steam and heat at the mines. Electrical machines produced 40,810 tons.

Edgar C. Weichel, of Scranton, who for the past twenty years has been a traveling inspector for the Pennsylvania Coal Co., has become an assistant mining engineer for the Hudson Coal Co.

A report on strikes in Pennsylvania during 1922 just made by William J. Tracy, chief of the Bureau of Mediation and Arbitration of the State Department of Labor and Industry, to acting Commissioner Walker of that department shows that the coal strikes in the anthracite and the bituminous districts of the state last year involved 322,806 men. The anthracite mines were idle for 132⅔ days and the bituminous mines for 106 days. Tracy estimated the number of days lost to the strikers in both fields at 38,000,000 days and the wages lost at $190,000,000. He based the financial loss to the workers on an average daily wage of $5. Involved in the strikes were 1,263 mines.

Shipments of anthracite in January, as reported to the Anthracite Bureau of Information, Philadelphia, amounted to 6,671,822 gross tons, as compared with 4,848,053 gross tons during the corresponding month last year, an increase of 1,823,769 tons, or 37.6 per cent. January of this year also showed an increase of 216,946 tons over the preceding month of December, when 6,454,876 tons were shipped to market. Shipments by originating carriers were as follows, in gross tons:

	January 1923	December 1922
Phila. & Rdg.	1,381,359	1,259,927
Lehigh Valley	1,093,052	1,107,745
Jersey Central	588,093	564,071
Lackawanna	1,038,719	938,530
Delaware & Hudson	741,739	832,893
Pennsylvania	596,989	561,603
Erie	750,277	738,073
N. Y., O. & W.	178,072	159,829
L. & N. E.	303,522	292,205
Totals	6,671,822	6,454,876

For the purpose of bringing all the mining men of the Centre-Clearfield region together to discuss the problems before them, a meeting was held Feb. 3 in Philipsburg, at which time an organization to be known as the **Moshannon Coal Mining Institute was formed.** There were present forty-eight mining men representing twenty-six coal companies from the towns of Clearfield, Curwensville, Woodland, Morrisdale, Munson, Winburne, Grassflat, Philipsburg, Osceola Mills, Houtzdale, McCartney, Sandy Ridge, Tyrone and Johnstown, as well as representatives from several mine supplies companies. After organization, it was decided to make a further effort to have all the interested men in the region present at the next meeting, the time and place, as well as the nature of which to be decided upon by the executive committee. C. B. Maxwell was elected president; Thos. A. Mather, first vice-president; James L. Lewis, second vice-president; George H. Brighton, third vice-president; Thomas F. Morgan, secretary-treasurer; James W. George, assistant secretary-treasurer, and the executive committee as follows: Joseph Knapper, D. L. Boyle, H. S. Shillingford, William George, Fred Pepper.

The assessed valuation of the coal beneath the surface within the city limits of Wilkes-Barre for the year 1922 was $21,633,079, from which will be deducted $317,254, abatements for coal mined during the year, leaving the **valuation for 1923, $21,315,824**, on which the city hopes to receive as taxes $213,158.24.

S. M. Casterline, who for many years has represented the Fairmont Mining Machinery Co. has been made sales manager of the American Mine Equipment Co., Pittsburgh.

Under the provisions of a bill introduced in the House by John E. Stavitski, of Luzerne County, the owner of a mine or an operator who neglects or refuses to furnish a sufficient supply of pure drinking water for the use of employees in the mines is liable to a penalty of $50 for each day of such neglect.

Local Union No. 5256, United Mine Workers of America at Jerome, Somerset County, at a recent meeting **decided in favor of continuing the strike**, thus indorsing the action of the district board and officers of District No. 2 in ordering a referendum vote.

A committee of the Central Pennsylvania Coal Producers' Association held a conference in Altoona recently **to formulate car-distribution and mine-rating rules.** This meeting was held in response to a request from the Interstate Commerce Commission, which asked the operators and the Pennsylvania R.R. to agree on rules. The conference was attended by President B. M. Clark, of Indiana; Vice-President G. Webb Shillingford, Secretary Charles O'Neill and Commissioners John C. Forsythe, J. William Wetter, Leslie Wallace, Mr. McDougall, A. H. Wilson and E. W. Derringer. This committee will meet with a committee of the railroad company later. The rating which a mine receives depends upon its capacity per day and the car distribution must be determined when the car supply is less than 100 per cent. There has been much complaint on the part of the operators relative to the distribution of cars, the claim being made that it is inequitable. Production in the district is far below the standard.

UTAH

John Crawford, state mining inspector, has issued a warning to coal mining superintendents and foremen in which he says none but authorized shotfirers must fire blasts. Mr. Crawford called attention to the recent deaths from this cause and says prosecution will follow if the rule of the Industrial Commission in this respect is not adhered to.

A bill to amend Section 3932 of the compiled laws of Utah, 1917, **relating to check weighmen in coal mines** has been introduced in the Legislature. It would compel operators to deduct pro rata from the pay of miners and pay the check weighman at the same time the miners are paid.

The MacLean Coal Co. has been incorporated for $500,000 The new company owns 2,000 acres of coal lands in Spring Canyon, Carbon County, known as the Mac Lean mine. Incorporators are: W. D. MacLean, W. M. MacLean, L. B. McCornick, J. J. Welch and G. S. Payne. W. D. MacLean is general sales agent for the Standard Coal Co., Kearns Building, Salt Lake City.

VIRGINIA

A coaling station for barges and small vessels, costing in the neighborhood of half a million dollars, is being promoted to be established on the waterfront in Berkley, on the south side of Norfolk. Capital in Philadelphia and Norfolk is to be employed in the project, according to the best information obtainable.

D. A. Butler, Norfolk manager for the Fort Dearborn Coal Co., has resigned that position to return to the accounting business, in which he was formerly engaged. He will open an office in Norfolk.

The Virginia Coaling Corporation, at Norfolk, has increased its capital to $25,000.

The Eastern Coal & Export Corp., of which L. S. Evans is president, and which is located at Richmond, has increased its capital stock from $500,000 to $750,000.

WEST VIRGINIA

A special meeting of directors of the **Pond Creek Coal Co.**, has been called for March 1 in New York **to discuss dissolution and liquidation of the company**. The property was recently sold to Henry Ford. It is reported that the directors will declare a final liquidation dividend of $10 a share. This dividend, when declared, will bring the total payment to $45 a share. Ford paid $8,500,000 for the entire property and equipment of the company, which, with current assets, was equal to $45 a share on 212,920 outstanding shares of stock after payment of taxes and all liquidation expenses. A first dividend of $35 a share was declared Feb. 15.

The Pound Mountain Coal Co. has been incorporated at Huntington with a capital of $100,000; John R. Evans, C. W. Campbell and E. D. Campbell are the incorporators.

G. D. Miller, Frank Enslow and R. H. Cunningham have organized the **Basic Coal Co.** at Huntington.

Charleston capitalists are said to be largely interested in the **Flynn Coal & Coke Co.**, recently organized with a capital of $50,000 to develop Fayette County coal properties. Among those interested are Daniel K. Flynn, of Elmo; H. B. Beury, James Flynn, A. S. Guthrie and J. A. Flynn, all of Charleston.

A new corporation has been formed by the interests back of the Pond Creek Coal Co., which recently disposed of its coal properties in Kentucky to Henry Ford. It will be known as the **Pond Creek Pocahontas Co.** and will operate in the Pocahontas field in West Virginia. The company has acquired mines with an annual tonnage of about 750,000, or about 150,000 tons less than the current tonnage rate of the Pond Creek Coal Co. The capitalization of the new company consists of 125,000 shares of no par value common stock. F. B. Davis, president of the Pond Creek and Island Creek companies, is president of the new corporation. The directors are Ben P. Bole, J. A. Downs, I. D. Francis, Frederick H. Goff, Charles G. Rice, Galen L. Stone and Mr. Davis.

The County Court of Monongalia County, W. Va., has instituted action **to set aside the sale of bonds of the Wheeling & Morgantown Ry. to Samuel Pursglove** of Cleveland, receiver of the road, the sale having been authorized by the county court last year. Since then the personnel of the court has been changed. In taking such action the new county court instructed the prosecuting attorney of Monongalia County to unite with counsel for the plaintiff in the case of R. H. Jarvis et al. against Samuel Pursglove. The bonds of the railroad, owned by the county, were sold for the sum of $162,500, the face value of the bonds being $325,000, plus accrued interest.

Henry Ford may extend the Detroit, Toledo & Ironton R.R. into the coal fields of West Virginia, according to assertions made by him Feb. 17 at Williamson, W. Va. His road now runs within 80 miles of Williamson. "We could haul coal to Detroit, make the product into coke, and sell it at a reasonable figure," he said. "If plans for the extension go through, the entire line would be electrified," he said. "We would develop the Ohio River just as we plan to develop Muscle Shoals," said Mr. Ford, "using hydroelectric power to move our trains and for other industries." He declared that he is now selling coke at $8 a ton in Detroit, and making a profit.

The E. E. White Coal Co. is planning to initiate work on the **new steel tipple** at its Glen White plant about April 1 with a view to having the tipple ready for operation by Sept. 1. The tipple will differ from the ordinary tipple in that only run-of-mine will be loaded over it and yet the degree of preparation and cleaning will be such as to meet the requirements of the most exacting market, it is stated. Other improvements are contemplated for the Glen White plant, all with a view to keeping the plant up to its degree of efficiency.

New coal companies organized in West Virginia during January had an aggregate capitalization of $6,850,000, there being 27 coal concerns in all formed during the period mentioned, two of which were non-resident. As two of the coal companies organized have capital stock without par value, the combined capitalization actually is in excess of the figures given. The largest among the coal companies organized was the **Mountain State Coal & Gas Syndicate** with a capital stock of $2,000,000. Other companies organized were as follows: **The Katona Coal Co.**, 1,000 shares without par value; **Bar-Jay Coal Co.**, of Philippi, $150,000; **Edna Gas Coal Co.**, of Fairmont, $1,500fi000; **Faith Smokeless Coal Co.**, of Beckley, $200,000; **Fairview Coal Co.**, of Webster Springs, $50,000; **Norwood Coal Co.**, of Omar, $1,000,000; **Pond Mountain Coal Co.**, Huntington, $100,000; **Profets Coal Co.**, Fairmont, $10,000; **Basic Coal Co.**, Huntington, 7,400 shares without par value; **Glenbar Coal Co.**, Clarksburg, $100,000; **Rich Mountain Sewell Coal Co.**, of Elkins, **$75,000; Shady Fuel Co.**, of Oxley, $25,000; **McKone Coal Co.**, of Tunnelton, $200,000 **Morganette Coal Co.**, of Beckley, $400,000; **Number One Coal Co.**, of Grafton, $5,000; **Hutton-Beale Coal Co.**, of Fairmont, $50,000; **Black Ash Coal Co.**, of Beckley, $15,000; **Riverside Coal Co.**, of Morgantown, $150,000; **Ideal Coal Co.**, of Charleston, $150,000; **Jackson Run Coal Co.**, of Clarksburg, $60,000; **Erwin Black Coal Co.**, of Charleston, $150,000; **Fire Creek Pocahontas Fuel Co.**, of Huntington, $150,000; **Flynn Coal & Coke Co.**, of Sunny Side, $50,000; **Coe Pocahontas Coal Co.**, of Covel, $200,000; **Brownsdale Coal Co.**, of East Liverpool, Ohio, $50,000; **Sanders Run Coal Co.**, of Pittsburgh, Pa., $10,000.

The following West Virginia coal companies have **increased their capital stock** in the amounts given: **Coal River Collieries Co.**, of Huntington, from $200,000 to $250,000; **Gulf Smokeless Coal Co.**, from $200,000 to $3,000,000; **Logan Fuel Co.**, from $25,000 to $100,000; **Independent Coal Co.**, from $50,000 to $100,000; **National Coal Mining Co.**, from $50,000 to $150,000.

Despite conflicting reports it is stated in reliable quarters that there has been a **settlement of the claim of the Willis Branch Coal Co.** against the United Mine Workers and that the sum paid over to the coal company was $400,000. John L. Lewis, International president of the United Mine Workers, has denied any such settlement.

Roy H. Cunningham and others prominent in the coal trade of southern West Virginia have organized the **Piedmont Coal Co.**, the capital stock of which consists of 20,000 shares without par value. Associated with Mr. Cunningham in the new venture are C. W. Strickland, G. C. Garred, James E. Hart and E. E. Winters, Jr., all of Huntington, where the general offices of the company are to be located.

Five men were injured, one seriously, in an **explosion Feb. 19 at No. 7 mine of the Island Creek Coal Co.**, Holden. Mine-rescue crews were reported searching Feb. 20 for two miners that were missing. According to mine officials, the explosion resulted when a car was derailed, filling the shaft with dust.

The new dry-process coal cleaning plant at the Crane Creek mine of the **American Coal Co.**, near McComas, was completed late in February and was scheduled to have its test run at once.

A news item in *Coal Age* Dec 28, 1922, stating that a fire due to spontaneous combustion threatened the destruction of a 35,000-ton storage pile of coal belonging to the Amherst Coal Co., at Amherstdale, W. Va., was a mistake. The Amherst company states that while it maintains "large stores of coal, this storage has never even been threatened with spontaneous combustion, even though one of the piles remained intact from December, 1920, to July, 1922, a period of eighteen months."

CANADA

In the year ended Jan. 31 **the United States sent to Canada 2,676,036 tons of anthracite**, duty free, valued at $23,364,988, and **10,327,450 tons of bituminous coal**, valued at $37,578,581, on which duty of $4,680,116 was paid, Secretary of State Copp announced Feb. 21 in the House of Commons at Ottawa.

During the week after the explosion of Feb. 8 which killed 33 men at the Canadian Collieries No. 4 mine, at Cumberland, Vancouver Island, a mass meeting of miners was held when the following resolutions were passed: **"That the exclusion of Orientals from all mines be demanded.** (2) That the longwall system of operating mines be eliminated. (3) That the meeting condemns Mr. Menzies, member of the Provincial Legislature for the district, for the statement alleged to have been made by him during the last session of the Legislature, to the effect that the miners and the company were satisfied with the result of the investigation into the cause of the previous explosion and with conditions at the mine." Trade unions in Vancouver threaten to boycott dealers that sell coal produced at mines where Oriental labor is employed. The Provincial Government has donated $5,000 toward the relief of the sufferers from the explosion and public subscriptions have been started in the cities of Vancouver and Victoria.

WASHINGTON

The War Department has called for bids for 2,000 tons of run-of-mine coal for delivery at Chanute Field, Ill., 824 tons of lump for use at Fort Omaha, Neb., and 100 tons of lump for use at Scott Field, Ill. Bids were scheduled to have been opened Feb. 27 at the Chicago Depot of the War Department.

Traffic News

F. R. Wadleigh, Federal Fuel Distributor, has asked the Interstate Commerce Commission to withdraw Service Order 38, under which the Montevallo Mining Co. of Aldrich, Ala., receives during the present coal car shortage priority rights to the use of 300 coal cars over its regular allotment.

The I. C. C. has authorized rail and barge rates and joint rates on coal from Alabama coal fields to Mobile and New Orleans for export.

The New York Central R.R. coal traffic department on Feb. 23 issued Supplement No. 10 to Summary of informal embargo notices No. 4, as follows: On account of accumulation **embargo 298 is placed by the New York Central R.R.** against **all freight** for delivery to the Fonda, Johnstown & Gloversville R.R. except perishable freight and anthracite coal, also bituminous coal when covered by permit issued by J. N. Snider, coal traffic manager, New York City.

To prevent congestion **embargo 303** was placed Feb. 21 by the **New York, Ontario & Western Ry.**, effective at once, against all shipments of coal from connecting lines (by rail or flat) at Weehawken, N. J., also New York and Brooklyn stations, piers or terminals; no exceptions.

The embargo placed by the Erie R.R. against all shipments of coal for the Passaic Worsted & Spinning Co., Dundee, N. J., **has been entirely cancelled.**

To prevent accumulation the **New York Central R.R.** on Feb. 22 **issued embargo 305** against all carload and less than carload freight destined to points on or via the New York, New Haven & Hartford R.R. and Central New England Ry., except livestock, perishable freight, anthracite coal, railroad fuel, freight consigned to officers of the United States Government. Shipments covered by permits issued by C. J. Brister, assistant vice president, Chicago, or G. C. Woodruff, general freight agent, New York City.

On account of accumulation the **New York Central R.R.** issued Feb. 22 **embargo 230-A** (superseding embargo 230), all carload and less than carload freight destined to points on or via the Boston & Maine R.R., except livestock, perishable freight, anthracite coal, railroad fuel and freight consigned to officers of the United States Government. Shipments covered by permits issued by C. J. Brister, assistant vice president, Chicago, or G. C. Woodruff, general freight agent, New York City.

At a conference of railroad officials representing the Virginian Ry. and coal operators shipping over that railway held in Charleston, W. Va., on Feb. 20, **regulations governing the shipping of coal were presented** by the railroad officials and agreed to by the operators, under the terms of which **shippers are to receive an equitable rating to be determined by the loading capacity of the mines.** Approximately 75 operators along the line of the Virginian are affected by the new rules and regulations, which become effective on March 1. The introductory period will be supervised by the allotment commission of the railroad and it is thought that with the new rules in effect there will be improved car distribution. Members of the allotment commission will visit the mines and under certain regulations will assist in arriving at a proper car apportionment basis. W. F. League will be chairman of the new commission, which is to have its headquarters at Princeton, W. Va.

A hearing will be held by the Coal and Coke Committee, Trunk Line Territory, in Room 401, 143 Liberty St., New York City, 2.30 p.m., Thursday, March 8, on a shippers' proposal for the **establishment of rates on bituminous coal** from the New River District of the Chesapeake & Ohio Ry. to Baltimore, Md., **on the basis of $3.65 per gross ton.**

The preliminary income statement of the **Delaware, Lackawanna & Western Railroad Co.** indicates that the coal strike resulted in a falling off of $11,355,000 in gross business for the year of 1922, as compared with the previous year. **Net income amounted to $10,475,928**, against $19,158,403 the year before.

Owing to the inability to get its cars back from other railroads, **coal loadings of the Pittsburgh & West Virginia Ry. are now only 40 per cent of car requirements,** Henry L. Farrell president of the company, says: "January net operating income will be favorable and will compare well with that of December," Mr. Farrell added.

Hearing on the joint petition of the Van Sweringen roads seeking permission to consolidate the New York, Chicago & St. Louis, the Chicago & State Line, the Lake Erie & Western, the Fort Wayne, Cincinnati & Louisville and the Toledo, St. Louis & Western roads into one system to be known as the New York, Chicago & St. Louis R.R. will take place at Buffalo on March 5. In New York only the "Nickel Plate" is involved, but similar applications are pending in other states and before the Interstate Commerce Commission. If ratified the new company also seeks to issue $32,720,000 in new preferred stock and $46,247,900 common stock. In the petition it is pointed out that the roads have been under common control for some time and that the consolidation would result in substantial economies and in improved service.

George S. Brackett, executive vice-president of the Northern West Virginia Coal Operators' Association, and several coal operators of northern West Virginia held a conference late in February in Pittsburgh with representatives of the Pennsylvania R.R. for the purpose of **discussing mine ratings.** A similar conference was held with representatives of the Baltimore & Ohio at the time the wage conference was held with officials of the United Mine Workers earlier in the month.

Another attempt is being made by the **Federal Valley R.R.**, which is owned and operated by the same interests that conduct the Black Diamond coal mine at Lathrop, Ohio, **to obtain relief from the Interstate Commerce Commission.** The railroad, which is 16 miles in length, was purchased by the Black Diamond Co. for the sole purpose of transporting the output of its mine. Other shippers along the line of the railway filed a complaint with the Public Utilities Commission of Ohio and obtained an order making the line a common carrier of freight. This added greatly to the burden of operating the line, as all freight is hauled at a loss due to disadvantageous divisions with connecting lines. It is contended that under present conditions the confiscation of the property ultimately will result. Such divisions of joint rates are asked as will permit this short-line railroad to pay its operating expenses, taxes and a fair return on the value of the property.

Preferences in the handling of privately-owned coal cars are condemned vigorously by S. C. Higgins, traffic manager for the New River Coal Operators' Association in a written argument filed with the Interstate Commerce Commission, in connection with the assigned-car case. "It is not in the public interest," Mr. Higgins says, "to give preference in the handling of private cars during the stress of car shortage, thus depriving shippers customarily dependent on system coal cars from distributing generally the products of the mines and using the limited facilities of the carrier in the movement of private coal cars, thereby disposing of the product in a restricted area." Mr. Higgins pointed out in his argument that during the car shortage on the Chesapeake & Ohio private cars are being placed at private-car mines greatly in excess of the distributive share placed at system mines. He further contends that both empty and loaded private cars receive preferential movement. Nelson W. Proctor, attorney for the Louisville & Nashville Ry., in taking exception to the contentions of the Commercial Coal Co. in the matter of rates on coal from eastern Kentucky mines to Northern and Western cities, declares that the mine operators have not shown these rates to be unreasonable. He says the present differences between the rates from L. & N. group 4 stations and group 3 stations are justified by the differences in distance and by comparison with the differentials obtaining between other coal groups. He declares that the grouping of mines in eastern Kentucky represents the best judgment of the traffic officers of the company and he states that the mine operators have not established that they are subjected to any unreasonable disadvantage as compared with the operators in group No. 3, who are nearer the markets.

Obituary

William Massie Warwick, superintendent of the operations of the Slab Fork Coal Co. in Raleigh County, W. Va., and for more than a quarter of a century prominent in the coal industry of southern West Virginia, died at his home at Slab Fork, on Feb. 8, of pneumonia. Mr. Warwick was 70 years of age.

Ora Darnall, 58, for many years connected with the Bolen-Darnall Coal Co. of Kansas City, Mo., died Feb. 10, in Battle Creek, Mich. Mr. Darnall in 1901 became general manager of the Bolen Coal Co. and not long afterward was made a partner in the concern. He moved from Kansas City to Wyoming twelve years ago.

James Mooney, widely known as an organizer for the United Mine Workers of America, who dropped dead recently in Kansas City, was buried in Novinger, Mo. Mooney had been a resident of Novinger and Connellsville for more than twenty years and had a wide acquaintance among miners not only in Missouri but throughout the United States and Canada, and he had been an organizer for this organization in both those countries for a number of years. He was attending a mine conference at the time of his death.

George Z. Hosack, treasurer of the Berger-Aiken Coal Co., of Carnegie, Pa., died on Feb. 9, after an illness of more than a month. He was a former treasurer of Allegheny County, and during his time had been associated with many coal companies.

George R. Stagg, superintendent of the Lehigh Valley Coal Sales Co. pockets at Irvington, N. J., died on Feb. 14 from pneumonia and influenza. He lived in Irvington.

James Omer Cole, 94 years old, the surviving original member of the lumber and coal firm of Cole & Crane, of Cincinnati, Ohio, died at his home in Peru, Ind., on Feb. 3. Mr. Cole owned considerable virgin timber land underlaid with coal in West Virginia.

Judge Martin A. Knapp, of the Commerce Court, formerly chairman of the Interstate Commerce Commission and long prominently identified with transportation matters, died Feb. 10.

Association Activities

Pittsburgh Vein Operators' Association of Ohio

The annual meeting of the Pittsburgh Vein Operators' Association of Ohio, comprising operators in the eastern Ohio No. 8 field, was held in Cleveland, Ohio, on Monday, Feb. 19, at Hotel Cleveland. The following officers and members of the executive committee were elected for the ensuing year: President, Michael Gallagher (re-elected); vice-president, Ezra Van Horn; treasurer, H. R. Sullivan (re-elected); secretary, D. F. Hurd (re-elected). S. H. Robbins, president of the Youghiogheny & Ohio Coal Co., was chosen chairman of the meeting in the absence of President Gallagher, who was unable to attend on account of the death of his mother. Colonel Henry L. Stimson and G. H. Dorr, of counsel for the bituminous operators' special committee, Washington, D. C., addressed the morning session, which had been especially arranged for the purpose of acquainting eastern Ohio operators with the progress being made by the national committee in preparing and presenting material facts concerning the industry before the U. S. Coal Commission. Non-member operators in the District were present as guests of the association at the morning session and also at the luncheon which followed.

Coming Meetings

International Chamber of Commerce will hold its second general meeting in Rome, Italy, March 19-26.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

Northwestern Pennsylvania Coal Operators' Association will hold its annual meeting March 6 at the William Penn Hotel, Pittsburgh, Pa. Secretary, T. F. Diefenderfer, Butler, Pa.

Canadian Institute of Mining and Metallurgy's annual meeting will be held March 7, 8 and 9 at the Mount Royal Hotel, Montreal, Quebec, Canada. Secretary, George C. Mackenzie, Montreal, Quebec, Canada.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., Dec. 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

Indiana Bituminous Coal Operators' Association will hold its annual meeting March 14 at Terre Haute, Ind. Secretary, P. H. Penna, Terre Haute, Ind.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

The executive board of the **Coal Mining Institute of America** will meet in Pittsburgh, Pa., Saturday, March 3.

The Gas and Fuel Section of the American Chemical Society is arranging a second sectional meeting at the New Haven meeting of the American Chemical Society during the first week in April. The section program will consist of papers on gas and fuel chemistry and a symposium on motor fuels, held jointly with the petroleum division.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, THURSDAY, MARCH 8, 1923 Number 10

Harry Harkness Stoek

IN THE death of H. H. Stoek the coal industry has lost a man of broad vision and progressiveness and yet withal one who made haste slowly. He was always careful and self-repressive in statement, a patient accumulator of information and one who never by overzeal supported a wrong cause. When acting as editor of the *Colliery Engineer* and *Mines and Minerals*—it bore both names—he made that paper one of the leaders in the technical journalism of its day.

He had great diplomatic ability, and this had much value at the time when largely by his efforts one of the most drastic of all mine laws was passed by the Illinois Legislature. In face of this fact Mr. Stoek always had the hearty support of the coal operators of Illinois. They in fact strongly approved the safety laws of their state though they always felt aggrieved with the fact that other mining states with which they had to compete did not have so severe a law to hamper their operations.

Professor Stoek labored hard to increase the percentage of extraction in Illinois; he brought together what information is available about subsidence; he carefully watched and recorded what developed in the matter of coal storage. As an organizer he was a man of much talent, a .d the work he did at the University of Illinois as head of the Department of Mining Engineering and the co-operation he attained in his educational work have made that establishment the leader in bituminous-coal mining of all scholastic institutions.

The Ins and Outs of Howat

THE Alex Howat case in Kansas certainly has its farcical aspect. It is humorous to picture the former president of District 14, United Mine Workers of America, popped out of this jail and that by the efforts of the new Governor of the state only to be popped in again by the efforts of the state Attorney General. But it is not so humorous to witness a Governor of a great state scorning the labor legislation on the statute books of his commonwealth and openly conniving with those elements of the citizenry within the state that would violate a law simply because it is distasteful and disobey a court because it is unpopular with them, as Alex Howat disobeyed the Industrial Court of Kansas.

Governor Jonathan Davis should prove the unconstitutionality which he charges against the Industrial Court Act and get that act repealed by due legislative course before he takes the doubtful case of Alex Howat in his own plow-calloused hands and attempts to settle it by freeing a prisoner of the state. He is setting an exceedingly bad precedent. The only relieving touch in the Howat episode is the ludicrous bungling of the Governor. He freely lavishes pardons and paroles upon the labor leader long ago discredited by his own national organization, but they do not mean anything. Some law enforcer always outwits the farmer Governor. And then Howat doesn't want his freedom anyway. When he is free he has to go to work. Periodical trips to jail, he seems to think, serve to keep alive the martyr worship he prizes so highly.

Coal Commission Able to Finish Its Work

CONGRESS in the end met every request of the United States Coal Commission, even to permission for Judge Alschuler to serve. An increase of 200 per cent in the appropriation, raising the total from $200,000 to $600,000, and some teeth in the law, making compulsory the answering of questionnaires, are the really important things, however, of which the added money is the more important. It is hoped that from now on there will be smooth sailing for the commission. Halting to get out the Jan. 15 report and several weeks of hesitation and uncertainty while the matter of added appropriation was being settled have slowed up to an appreciable extent the work in progress, and added to the doubts in the minds of the coal operators and the trade generally as to whether the whole thing might not blow up.

There is no reason now why anyone should delay sending to Washington data called for by the commission, unless it be the plain unvarnished desire to withhold. It is no secret that there are some coal operators and others who would like nothing better than to hamstring the whole program. It is fortunate that they are in the minority and do not represent the feeling of the majority of the leaders or of the rank and file. So far as we are aware the opposition to supplying facts to the coal commission centers in southern West Virginia. The feeling is quite general, however, that eventually this district will not only put in all the facts but that it will put them in just a little more complete and in better form than any other field. Whoever he may be, anyone will think hard and several times before giving the commission occasion to test the power of its authority.

The Elements of a Lake Program

WHEN coal and railroad men begin to talk about the "Lake program" for the coming season, all may know that spring is on the way. From the high point for recent years of 28,000,000 tons in 1918 to the low of 18,000,000 tons in 1922 the Lake coal movement has varied. The real point of difference between years is not the total, however; it is the rate of movement. The railroads are showing concern over the prospect of getting coal started early and in volume for the Northwest. The dock operators fear that unless the freight rates to lower Lake ports are reduced or the costs of

transportation from Eastern and Midwestern fields are otherwise more nearly equalized there will be a dearth of coal put on the docks this year.

The ideal program for the Lakes is one that starts out strong, reaching a high rate of dumping early in the season, and tapers off late in the summer. Such were the records for 1919 and 1921. Contrasted with these ideal performances were the records for 1918, 1920 and 1922, when the humps in the curve came late in the season. Recent history shows all too clearly the difficulties that arise when the movement of this essential coal is too long delayed. Pressure of all manner of sorts develops and too often Washington becomes involved in the effort to make up lost time.

It will be noted that the best years were the easiest, when the natural laws of trade operated to pour the coal northward for storage in transit at the time of year when demand was at low ebb elsewhere. The inaccessible Northwest is a market that requires that the greater part of its winter coal be taken during the open months of the year. The trade via the Lakes was developed to supply that need, and thus to take advantage of the opportunity to mine and ship coal not called for by local markets. The commercial dock companies of the Northwest were originally and are now to a large extent subsidiaries of Eastern coal producers, established to furnish a summer outlet for production.

Under normal market conditions, as prior to the war and in 1919 and 1921, when summer demand for coal is slack, these companies can and do put sufficient coal up the Lakes to care for that territory. But when market conditions are abnormal—that is to say, when there is a strong demand for coal in the summer in nearby markets—the shippers having contracts or other arrangements to send coal to the Lakes must needs share the available car and transportation supply with a host of other shippers having no such obligations. Between bidding in a high spot market to make up for contract coal curtailed by car shortage and appealing to the government for preferential treatment the Northwest has chosen the latter as in 1918, 1920 and 1922. In these years the necessary supply was literally forced into that route after it became evident that not otherwise would the necessary supply be shipped.

The coming Lake season will take one form or the other. If coal from the Eastern fields flows easily and in volume when the season opens, the 23,000,000 tons or more of soft coal that apparently will be required for the Northwest will be obtained without particular effort. The attitude of railroads, utilities, industrials and retail dealers in the Northwest toward their fuel commitments will have much to do with the development of an early, strong start. Delayed buying will bring another last-month rush and appeals for help.

Fundamentally Wrong

LOOK at it as we may there must be something fundamentally wrong or we would not have so many mine explosions as recently have occurred. It would be difficult to find three better disposed companies than the Woodward Iron Co., Phelps Dodge Corporation and the Weyanoke Coal & Coke Co., a subsidiary of the National Cash Register Co., in whose mines, nevertheless, explosions have recently occurred. The fact that the mine of the last-named company was operated by the Pattersons is a guarantee that little if anything would be spared to make the workings safe.

We may hope later to hear more of the details, and when we do we may find that what is said here about our American practice of building up coal far above the sides of the wagons does not apply to any of them. However, that practice is one of the arguments against rock dusting. With such a large quantity of spillage the rock dust, if used, would have to be loaded out frequently in order to keep the percentage of coal in the floor dust down to a safe figure.

This apparently is the real objection to rock dusting. It would seem to necessitate a change in our equipment, one that the loaders would resent because it would add to the difficulty of loading, and one the operators cannot feel disposed joyfully to accept because it would lower production, involve an immense expense and displease their men. We are getting wider and longer cars. We are building them closer to the tracks, but we are not keeping the old standards of height, for we are utilizing the advances in breadth, length and lowness of bed to obtain large capacity with lessened car depth. Furthermore, it is felt that the building up of the cars with lumps puts a premium on large coal and saves expense in the equipment provided for hauling, hoisting and dumping cars.

Doubtless these considerations weighed but little with the companies mentioned, but we are all creatures of habit, and the practice of rock dusting not being established because of these considerations, even the companies more prodigal in providing protection have not taken kindly to extensive rock dusting because precedents in the practice were almost entirely lacking in this country.

Furthermore, sprinkling and moistening of the atmosphere seemed as good and a less expensive method. Clearly, however, it has not proved a complete solution of the difficulty and the whole problem of mine protection must be considered from a new viewpoint.

The dangers of derailed cars can be met as far as feeders are concerned by putting them in a trench covered by a plank. The trolley line should be safeguarded by taking care that the timbers are so protected that derailment of a car or even of a trip of cars will not dislodge the posts by which the trolley line is supported. Where the roof tends to break up as the air weathers it the roadways should be protected by a thin coating of cement mortar, and big barrier pillars should be provided so that the roof will be free of a strain that would make the cement mortar an unavailing protection.

Unfortunately such pillars cannot be provided in room entries. Here the trolley locomotive might give way to the storage-battery unit where the roof is bad, but in that case how could current be supplied to the machines if the trolley system or a special feed wire were not provided? Attaching the trolley supports to the side would be no preventive of damage from roof falls should the roof give way, for if the rock fell on the wire or the trolley supports both would come down and cause a severe short-circuit. The danger of accident would be greatly minimized, however, if the heading were plentifully sprinkled with rock dust. With more cemented roadways, with rock dust liberally bespread and with cars that do not spill their contents over the roadways the dangers from explosions would be greatly lessened. We are facing a situation nearly as bad as that when the Monongah, Jacobs Creek, Yolande and Naomi explosions confronted us, and something will and must be done to make our mines safer.

Pocahontas Coal Field and Operating Methods of the United States Coal & Coke Co.*

Mining Methods Now in Favor—Performance of Undercutting Machines—Consumption of Timber per Ton and per Acre—Car Duty and Maintenance Costs—Output per Man—Power Consumption—Expenditures on Materials

By Edward O'Toole†
Gary, W. Va.

THE Pocahontas district occupies the extreme southern end of West Virginia, principally McDowell, Mercer and Wyoming counties, and a part of Tazewell County, in southwestern Virginia. The first record of the coal field is a report by Prof. J. P. Lesley, of Pennsylvania, about 1880, in which he mentions a coal opening at the upper end of Abbs Valley, Tazewell County, Virginia. C. R. Boyd, a mining engineer of Wytheville, Va., published a series of articles in 1881, mentioning coal on Indian Creek, Tazewell County, and on Horse Pen Creek, which coals, he stated, extended toward the Ohio River. He also mentions the Abbs Valley coal reported by Lesley.

In 1881 F. J. Kimball (who became president of the Norfolk & Western R.R. in 1883), after examining the Scott mine in Abbs Valley, went northward across Abbs Valley Mountain to the place now known as Pocahontas, where he located what has since been called No. 3 vein of Pocahontas coal. In November, 1882, Jed Hotchkiss and others prepared a cross-section of the Flat Top Mountain coal measures, some notes on which were published by Mr. Hotchkiss, between 1880 and 1892, under the title of "The Virginias."

In May, 1881, the Norfolk & Western R.R. was organized through the purchase of the Atlantic, Mississippi & Ohio R.R., an old line running from Norfolk, Va., to Bristol, Tenn., with branches from Petersburg to City Point and from Glade Springs to Saltville. At that time charters had been granted for three railroads tributary to the New River Valley, but their proposed routes would indicate that the promoters were concerned with minerals, timber and a connection with the Chesapeake & Ohio R.R. rather than the development of any coal in the Pocahontas district. One of them was projected to extend up Bluestone River a short distance, but not far enough to reach the coal in the Bluestone Valley, and a little grading was done for a narrow-gage road between New River Station and a point in Giles County, Virginia, near the West Virginia line. All charters and railroads in this district were acquired by the Norfolk & Western R.R. early in 1882, and during that year construction was actively prosecuted on this company's main line from near Radford, Va., to the Pocahontas coal field.

In the meantime the Southwest Virginia Improvement Co. began to open coal mines and build coke ovens at Pocahontas and vicinity, so as to be ready to make shipments as soon as the railroad should be completed, which was in 1883. Shipments began in June, and during that year 81,800 tons of Pocahontas coal and 23,763 tons of coke were shipped. From 1884 to 1888 the Norfolk & Western extended its lines down Bluestone River to Flipping Creek and up the latter. In 1888 it completed

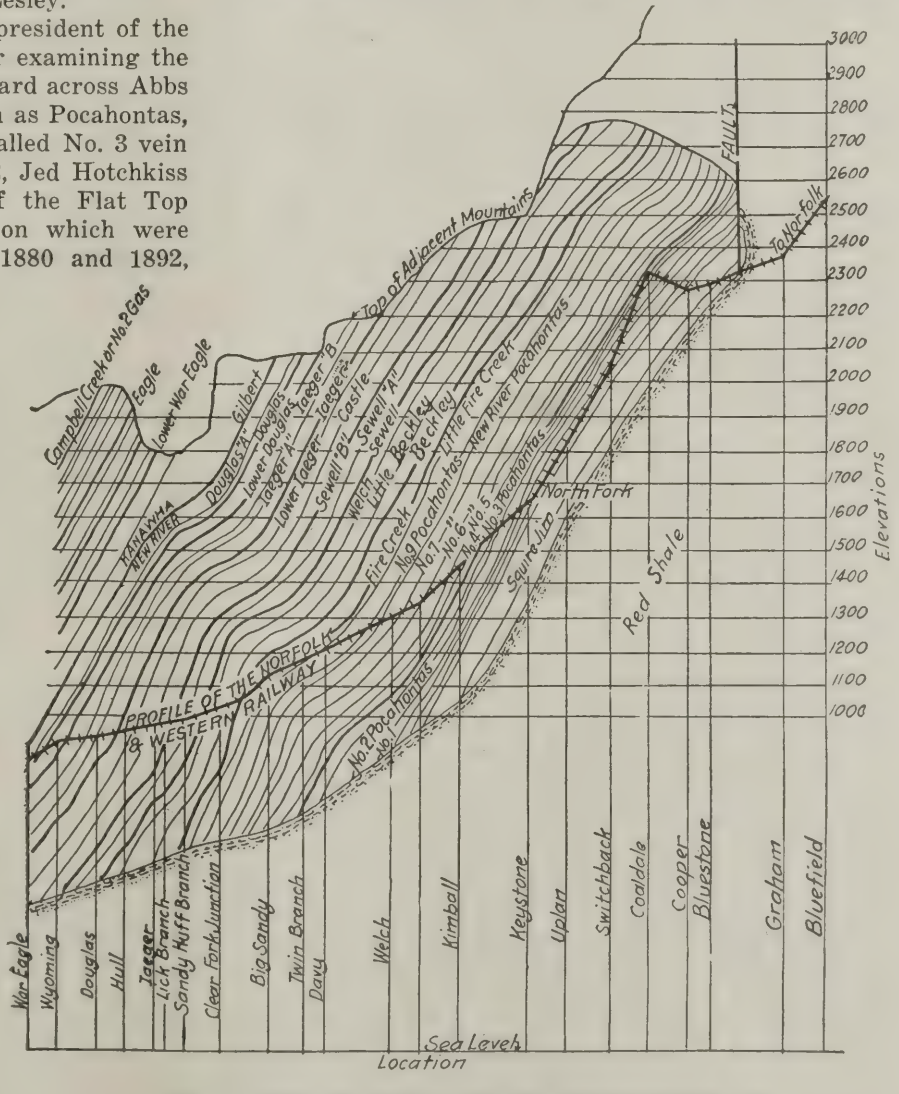

FIG. 1—PROFILE OF COAL SEAMS OUTCROPPING ON NORFOLK & WESTERN RY.

It will be noted that McDowell County not only has the Pocahontas, or Pottsville measures but, in the western end, the New River series and even part of the Kanawha series. However, this profile on the left oversteps the McDowell County line a little, Wyoming being in that county and War Eagle in Mingo. The Kanawha and New River measures lie unconformably on the Mauch Chunk red shale and so in a degree do the Pocahontas measures.

†General superintendent, United States Coal & Coke Co.

*Article delivered at the February meeting of the American Institute of Mining and Metallurgical Engineers, New York City, Feb. 20.

FIG. 2—NORFOLK & WESTERN RY. AND THE ADJACENT COAL FIELDS

This map does not show all the coal fields in the area presented but only those tributary in a degree to a railway system mentioned. Coal is found almost all over the area illustrated, Logan, Raleigh, Fayette, Boone, Kanawha and Letcher being important coal producers, and many of the others possessing some coal lands.

the Elkhorn tunnel and extended its line to Elkhorn, in McDowell County, West Virginia.

About 1886 to 1889 Messrs. McCreath and d'Invilliers made an extensive examination of the Pocahontas and adjacent coal fields for the Norfolk & Western R.R. Co. In 1890 construction began on the Ohio extension, which was completed to a connection with the Scioto Valley & New England R.R. at Ironton, Ohio, in November, 1892. This gave the Norfolk & Western an outlet to Columbus, Ohio and the West, and also to the Eastern seaboard at Lamberts Point, Va., where a coal pier had been erected in 1885 for the transfer of coal into ocean vessels. Another outlet was acquired by the purchase of the line from Roanoke, Va., to Hagerstown, Md. The railroad was reorganized as the Norfolk & Western Railway Co. in 1896.

The Pocahontas Coal & Coke Co., incorporated in 1901, is a land holding and leasing company and does not engage in coal mining or in trading in coal or coke. The areas held by this company have been increased from year to year, the present total being 300,000 acres. The largest single lease now is that of the United States Coal & Coke Co. The Crozer Land Association in the early period assembled 16,000 acres of coal land immediately tributary to the Norfolk & Western Ry., all of which is leased to mining operators.

The construction of the Tug River branch of the Norfolk & Western from Welch, W. Va., up Tug Fork and tributaries, for developing the leasehold of the United States Coal & Coke Co., was undertaken in January, 1902, and a second section in May, 1903. Fifteen miles were put in operation to and above Gary in June, 1904. Extensions in this valley have been made from time to time, and at present there are seventy-five miles of railroad on this branch.

According to I. C. White, state geologist of West Virginia, "The lowest and oldest rocks are the Mauch Chunk red shales, which crop to the surface in narrow belts along the crest of the Dry Fork anticline in the southeastern portion of McDowell County. The Pottsville measures, or basal formation of the Pennsylvanian, constitute at least 95 per cent of the outcropping rocks, the entire group being represented in Wyoming and McDowell counties." White also gives the sections, names and elevations of the coal seams of the Pocahontas coal field.

Fig. 1 shows a section (with greatly exaggerated vertical scale) along the Norfolk & Western Ry.; this road, except at the Elkhorn tunnel at Coaldale, follows the Tug River and Elkhorn Creek 15 to 20 ft. above their beds. So far as known at present, seven seams in the New River group, namely: Douglas, Iaeger "B," Iaeger, Sewell "B," Sewell, Welch and Beckley, are of workable thickness in McDowell County. Thus the Pocahontas coal field is not really synonymous with the McDowell County coal area, as has been quite generally believed.

Four of Pocahontas Seams Are Workable

Only four seams in the Pocahontas group, namely, Pocahontas Nos. 3, 4, 5 and 6, are known to be of workable thickness. No seam of either group is coextensive with the field. The thickest seam of the Pocahontas series is No. 3, which is 12 ft. thick at Pocahontas, but only 11 ft. in the Elkhorn tunnel, 3 miles from Bluestone; it gradually thins in a northwesterly direction until it reaches Kimball, 17 miles west of Bluestone, where it goes under water, with a thickness of 7 ft. On Tug Fork Branch, on the lease of the United States Coal & Coke Co., it is from 3 to 8 ft. thick.

The No. 4 Pocahontas seam on the lease of the United States Coal & Coke Co. runs from 3 to 7.5 ft. thick. These two seams are similar in character. The workable seams of the Sewell group, immediately above, have a maximum thickness of 5 ft. averaging about 3 ft. where worked.

As will be noted, the Pocahontas coals are found in the oldest coal-bearing measures of the Appalachian fields. Their present area is comparatively small, and is bounded by a fault on the southeast and by the edge of the basin on the east, north and west. All the coals in the Pocahontas field are low in sulphur, ash and phosphorus; it is seldom that an analysis shows ash more than 4 per cent, sulphur more than 0.6 per cent, or phosphorus above 0.008 per cent, unless portions of the overlying or underlying strata or of the partings have been included in the sample in which case these constituents run higher.

The topography of the Pocahontas coal field is exceptionally steep and rugged, consisting chiefly of high narrow ridges and V-shaped valleys, the latter affording limited space for railroads, highways and town sites. Much forethought is required in the planning of mining towns and plants. The fall of the main stream, Tug River, is approximately 0.5 per cent, except near its source. Railroads have been built along it and some of its branches with grades varying up to 3 per cent.

The climate is mild, and hard winters are of rare occurrence. The rainfall is unusually heavy, from 50 to 55 in. per year, and furnishes an abundance of water for all purposes except during the four or five dry months, when reliance must be placed on deep wells, as the stream becomes low and more or less polluted

This exceptionally heavy rainfall creates a serious problem in mine drainage.

The mountains were originally covered with abundant timber, but now all building material and about 80 per cent of the mine timbers is brought in from other localities, generally from Georgia, Alabama and Mississippi.

A large percentage of the labor now employed comes from the surrounding states and from foreign countries. The clerical, engineering, skilled labor and directing forces consist principally of native Americans, while the largest part of the manual labor is performed by the colored and foreign employees. The labor is well trained and efficient, diligent and loyal. There are no labor unions in the field, although there are various secret and benevolent orders among all classes of labor. All the mines of the Pocahontas field are served by the Norfolk & Western Ry.; the coal is easily accessible and outcrops on the mountain sides throughout the greater part of the territory.

Operating Developed Discontinuity of Beds

Previous to the entrance of the United States Coal & Coke Co. into the field, prospecting, drilling and correlating of the coal seams was done in a superficial manner. The operating companies were small and their holdings consisted of leases 3,000 acres or less in area. The land-holding companies found no necessity for prospecting up to that time.

Before it had thoroughly inspected its property the United States Coal & Coke Co. began the development of the Tug River section, and started to build its railroads and towns. The Pocahontas No. 3 seam had been thoroughly developed along the Elkhorn River by operating mines, and it was supposed that this seam continued through the mountain to the valley of the Tug River, but when the seam was developed at many points on the Tug River front it was found that in every opening the coal pinched out at a distance varying from 50 to 800 ft. from the outcrop.

As railroad and town building had been pushed vigorously, much expense had been incurred prior to the time when the coal disappeared. To avoid further loss the property was now most thoroughly prospected by outcrop openings and diamond-drill borings. Openings were started every 1,000 ft. along the entire outcrop of No. 3 seam, a distance of 105 miles, and openings were made also on other seams. Diamond-drill cores were taken at desirable points, ranging from 1,000 ft. to 5 miles apart. This work developed the fact that the openings on the Tug River side of the mountain were not in the famous No. 3 Pocahontas seam but on the No. 4 seam, 65 ft. above it. It further developed that under a considerable area both the No. 3 and No. 4 seams were wanting, but that, on the other hand, these two seams were in place, of good minable thickness, over a large portion of the property, and that the total area carrying both seams exceeded by about 20,000 acres the amount expected at the beginning. Had the property been only partly prospected at the start, disclosing that No. 3 seam was wanting over a large portion of the territory, and that the outcrop openings were on No. 4 instead of No. 3 seam, the lease probably would have been abandoned and development would have been retarded for years.

In the calculation of available tonnage a line 80 ft. inside the outcrop was taken as the limit of merchantable coal. The actual distance from outcrop to good coal averages 77 ft., thus confirming the estimate. The yield was estimated at 1,500 tons per acre-foot and this also has proved a fairly accurate assumption.

The United States Coal & Coke Co., a subsidiary of

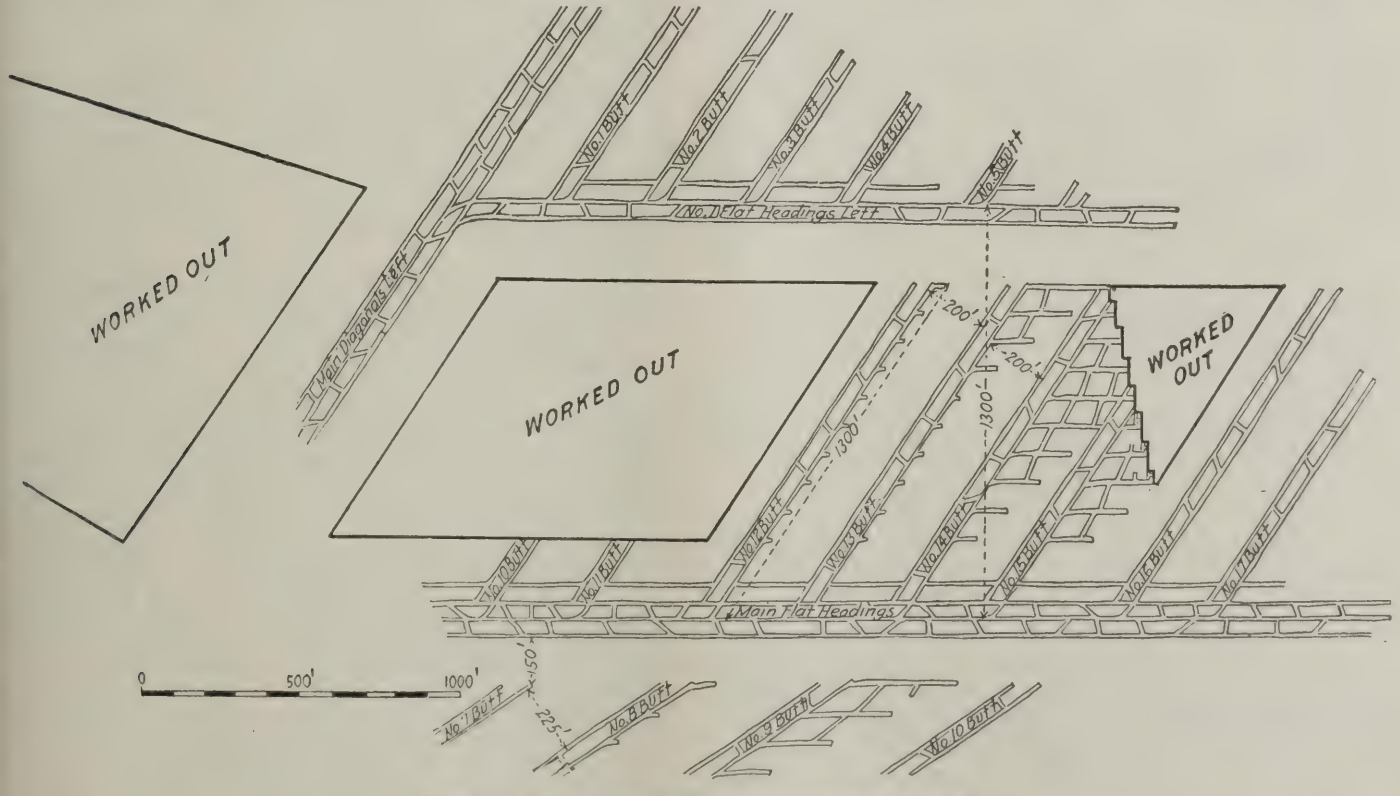

FIG. 3—OLD METHOD OF WORKING BY PANELS

This was the first method of mining that the Pocahontas region adopted. It was a slow way of developing the coal and an expensive way of extracting it. Too many roads had to be maintained, the ventilation was costly, coal was lost, too much territory was kept open, too much capital was needed for equipment, and supervision was difficult, resulting in high cost for this service and decreased safety to the men employed. Consequently the United States Coal & Coke Co. discarded it.

the United States Steel Corporation, is the largest coal producing company in West Virginia; its operations consist of one shaft, one slope and twelve drift openings. The shaft, which is 180 ft. deep and penetrates both No. 3 and No. 4 Pocahontas seams, has not been in operation since 1909. It is now used as a drainage outlet for the northern portion of the property.

The mines on this property at first were developed by the panel system. These panels were about 1,000 ft. square, and were developed with a set of main headings, comprising one haulage road and two airways. The intention was to drive the room headings from these main headings to the end of the panel before any room work or rib extraction was started. This method was soon found defective in the following principal respects: (*a*) Excessive time spent in development; (*b*) short life; (*c*) expense of mine roads, side tracks, etc.; (*d*) expense of ventilating; (*e*) expensive to operate principal haulage; (*f*) excessive quantity of coal left as barrier pillars; (*g*) loss of large percentage of this coal when pillars are removed; (*h*) large area remaining open for a given tonnage; (*i*) large quantity of equipment required for a given output; (*j*) excessive cost of proper supervision, due to scattered workings; (*k*) dangerous conditions, for the above reasons.

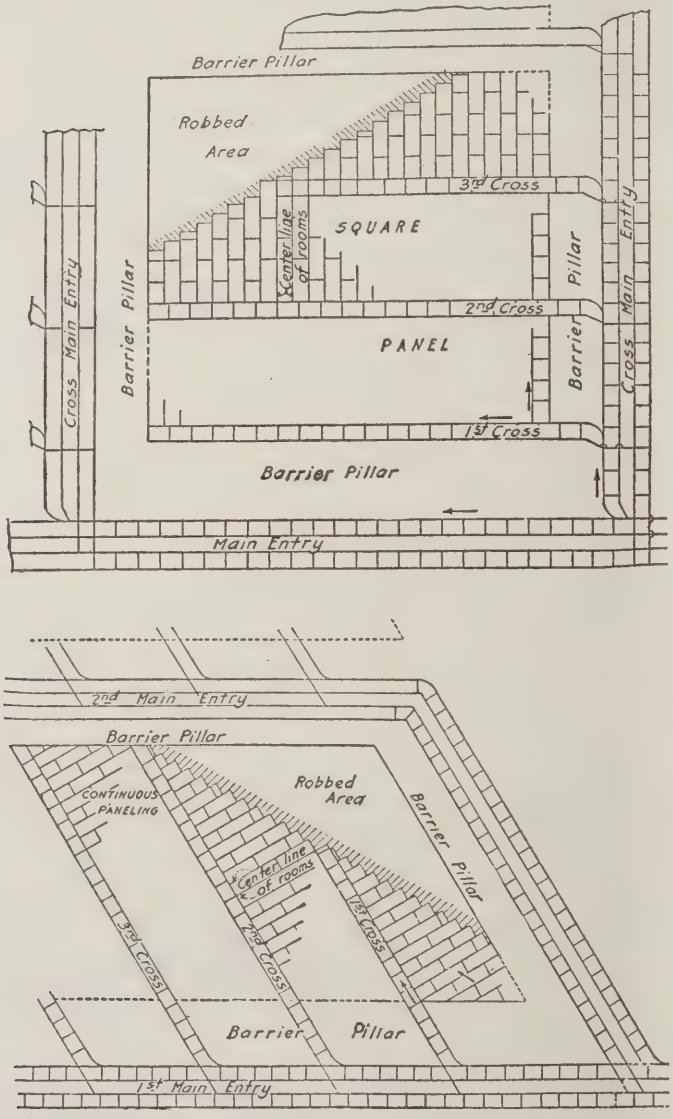

FIG. 4—TWO TYPICAL PLANS FOR WORKING A PANEL

These are standard methods in the Pocahontas region. Three cross entries are driven up for their full length and then rooms are started, the first room being at the end of the heading and the last against the barrier pillar of the cross main entry. The rooms are pillared retreating, giving a long pillar line which passes from cross entry to cross entry.

From a portion of mine No. 6, originally developed by the old panel system in 1904, ribs and pillars of rooms that were driven at that time are still being extracted, and it will require not less than six years more to exhaust this part of the mine. Fig. 3 shows a plan of the old system, now discarded by this company.

The principal methods of mining in the Pocahontas field were described in 1915 by William H. Grady, in a paper, "Cost Factors in Coal Production."[1] Fig. 4 is one of a large number of illustrations in Mr. Grady's paper; it shows the details in the exploitation of two individual panels of different shapes. These systems, with slight modifications, are still in use throughout the field.

The Pocahontas No. 3 and No. 4 are the fourth and fifth seams from the bottom of the series, the interval between them being 65 to 70 ft. A typical section of each seam is shown in Fig. 5, that of No. 3 being as it occurs in mine No. 10, while the section of No. 4 seam was measured in mine No. 6; these mines are about 1½ miles from Gary and located in different valleys.

Explosive Gas Is of Frequent Occurrence

The slate overlying No. 3 seam thins out in a northeasterly direction until it practically disappears, while the slate overlying No. 4 seam thickens in a southeasterly direction until it reaches a maximum of 5 ft., before it begins to thin, and it entirely disappears in the extreme southwestern extent of the seam. The roof of No. 4 seam varies from a sandstone, lying directly over the coal, to a laminated coal and slate (known locally as "rash"), which gradually appears between this sandstone and the coal until it has reached a thickness of 5 ft.; it is then gradually displaced in a southwesterly direction, from top down, by a slate which attains a thickness of 6 ft., when it in turn gradually disappears. Where slate or black "rash" is over the coal, it renders the mining conditions difficult and dangerous.

Till quite recently explosive gas has not been present to add to the ventilating problems of the mines of the United States Coal & Coke Co.; however, in those parts of the seam under heavy cover, a small quantity of explosive gas is found, which increases as the mine workings advance. The seams dip northwesterly from 2 to 8 per cent.

About 97 per cent of the coal in the Pocahontas region is mined through drifts on the mountain sides at various distances above the stream. The entrances are protected in various ways, such as timbering, stone side-walls with I-shaped cross beams, stone side-walls with stone, brick or concrete arches.

From the drift openings coal is delivered to the railroad by electric trams, steam trams, gravity planes, aerial tramways, retarding and scraper conveyors, pan conveyors and chutes.

The description of development plans will be confined to the practice followed by the United States Coal & Coke Co. at its mine No. 6, operating in the No. 4 Pocahontas seam, this plant being fairly typical of mining practice in the Gary district.

The general plan (Fig. 6) is a room-and-pillar continuous advancing and retreating system. While advancing, room ribs, heading stumps and heading chain pillars are extracted. Thus the full production of the mine can be constantly maintained from a short period

[1] *Trans.* (1916), Vol. 51, p. 138; previously published in *Bulletin* 101 (May, 1915), p. 1,035.

after beginning until the mine is practically exhausted. Each section is planned for a minimum capacity of 1,000 tons per shift, both while advancing and retreating; in practice this output is being exceeded.

During the advancing period the headings are continually progressing and rooms are being driven on the "inbye" end of them. As soon as these rooms reach their limits, the pillars are withdrawn, resulting in complete extraction over that portion of the section allotted to the advance. By this plan the room headings last throughout the life of the mine and become as long as the property; some such headings are now more than 6,400 ft. long and have two miles further to go before reaching the boundary. The life of one of these sections may be from 10 to 40 years.

Concentration of Workings Afforded

This method affords simplicity of ventilation, transportation and drainage; concentrates the workings and permits a maximum of superintendence. No standing pillars, with resultant open work to be ventilated, are left for later difficult and expensive extraction. It is never more than two years from the time a room is started until it has reached its limit and its ribs have been robbed back to the heading.

On all haulage roads 0000 grooved trolley wire is used, and both rails are bonded. Feeder lines of 1,000,000 and 500,000 circ.mil, paralleling the trolley wire, to which the latter is connected every 200 ft., are carried on the same hanger blocks. (See Figs. 7 and 8.)

The power from a central power plant is distributed to substations, one of which is at the mine entrance and the other 9,000 ft. inside. These substations are designed to run in parallel and furnish an even distribution of power at the working face and along the haulage roads. Direct current of 275 volts is used for all underground power, including lighting, haulage and undercutting.

Electric Lights One Hundred Feet Apart

On all haulage roads, electric lights are installed at 100-ft. centers and on curves one is set every 75 ft. In rooms two or more electric lights are maintained at the face, and one light at the room switch on the heading. (See Fig. 9.)

During robbing the measures generally break to the surface, and as there is no alluvial deposit or surface soil on the tops or sides of the mountains, the cracks remain open and a large quantity of water enters the worked-out areas, especially at certain seasons of the year.

The mines are drained by a tunnel driven in the coal seam as near as possible to the low side of the property. All water from this and adjacent higher mines drains to this waterway. This tunnel is part of a drainage system extending through other mines from the lowest outcrop point on the Tug River. During a period after heavy rains, weir measurements showed 12,000,000 gallons of water passing through the drainage tunnel in 24 hours. This water came chiefly from robbed areas.

All undercutting is done with electrically driven shortwall mining machines which are equipped with cutter bars varying from 6½ to 12 ft. long. Room and heading coal and also rib coal, when solid, is undercut. The coal in stumps and pillars which have sufficient weight upon them to crush the coal is removed by hand. The cover over the working places in mine No. 6 at present is so heavy that it is necessary to undercut only

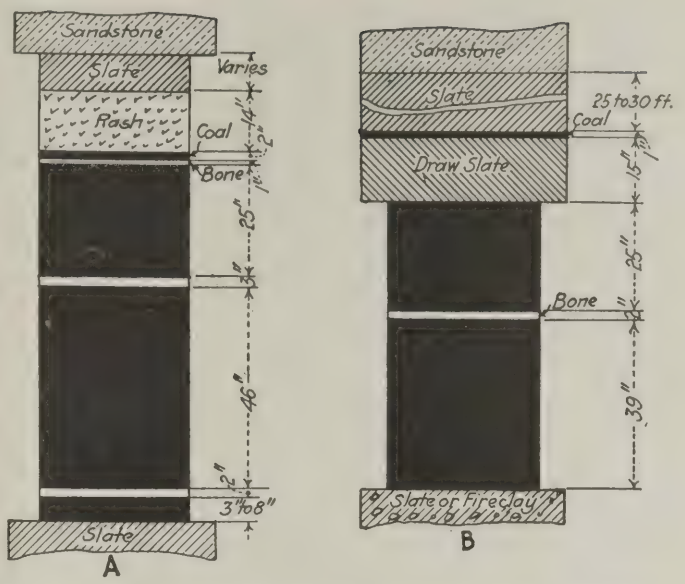

FIG. 5—CROSS SECTIONS OF LEADING GARY SEAMS

A is No. 3 seam, the fourth from the bottom of the Pottsville series. The slate thins out in a northeasterly direction. *B* is No. 4 seam. In places the sandstone is found immediately over the coal but in other places it is 30 or more feet above it. The draw-slate may change to laminated coal and slate, and in that case is dangerous.

42.5 per cent of the coal mined. Table I shows the work done by all mining machines in the company's properties:

TABLE I—PERFORMANCE DATA OF MINING MACHINES

Mine No.	Days Worked	Places Cut	Machines in Service	Places Cut Per Machines Per Day	Tons Machine Coal Per Machine Per Day
2	241	9,512	7	5.6	193
3	248	11,759	7	6.8	103
4	245	6,751	7	3.9	114
5	234	3,291	3	4.7	175
6	239	5,960	9	3.2	129
7	240	13,217	9	6.1	185
8	235	7,426	4	7.9	195

10	227	10,275	11	3.9	82
11	247	19,534	10	7.9	136
12	240	7,019	4	7.3	250

In the above tabulation "Machines in Service" means the total number of machines fit for duty. The figures under "Tons per Machine per Day" are based on the total number of machines at each mine and do not show the actual individual performance because the plants have more mining machines than necessary, these having been provided for the old panel system of mining.

When blasting machine-mined coal in narrow places the coal is likely to be broken excessively but in wide places the size of the product is the same as that of hand-mined coal. In places 36 ft. wide or more, and sometimes in places as narrow as 11 ft., where the cover exceeds 600 ft., the weight of the mountain breaks the coal down from the face while it is being undercut.

Holes for blasting coal are of 1¾ in. diameter and are drilled by hand with one-man twist augers. Their average depth is nine-tenths the depth of the cut. The miner drills and charges his holes with a permissible explosive and electric detonator, and tamps them with clay brought from the outside. The charge is fired by the assistant mine foreman during the day shift, with a pocket battery which he carries for that purpose.

Rooms are turned on a schedule which permits pillar extraction to commence immediately upon their completion (Fig. 6). They are spaced on 125-, 90- and 75-ft. centers, and are driven 60, 36 and 24 ft. wide, according to thickness of cover and roof conditions.

Only one track is required in places 18 ft. or less in

width. Track is laid next to the "outbye" side of the room in advancing sections and is aligned by sights. Places 36 to 40 ft. wide have two tracks, one on each side of the room, and sights are used to keep these rooms in proper alignment. In rooms 60 ft. wide three tracks are used, one in the center of the room and one on each side. With rooms 36 ft. or more in width only one cross-cut is driven between rooms, this being 80 ft. from the heading; ventilation is maintained from this point by a wooden brattice in the center of the room. (See Fig. 10.)

Partings in the seam are picked out by the miners and gobbed. The amount of bone thus removed by the miner is approximately 5 per cent of the seam. The coal is soft, has no definite cleavage planes and breaks with a columnar fracture. There are three bone partings in No. 4 seam, one being a few inches above the floor, another in the middle of the seam, and one 2 or 3 in. from the top. The bottom parting and the coal below it, which is only a few inches thick, are not mined. The middle and top partings are mined with the seam and partly removed by the miner before loading; but the 10 to 14 in. of overlying "rash," being soft, breaks into small particles, mixes with the coal and is loaded with it.

No timbering is permitted on haulage roads without written permission of the general superintendent, which is given only in exceptional cases. Where the roof is bad it must be taken down until all loose material is removed. Concrete posts are used on main headings where permanent support is required.

Timbering in rooms follows a standard plan (Fig. 10). Timbers having a minimum diameter of 5½ in. are used. A row of "road posts" is set parallel to the room track, 2 ft. from straight track or 30 in. from curved track, and 3 ft. apart. A cap piece 6 ft. long, placed on the top of each road post, extends over the track. The other timbers, "gob posts," are spaced 6 ft. apart and use a cap piece 4 ft. long. Timbers are maintained at a distance not greater than 6 ft. from the working face, irrespective of condition of roof, and closer where necessary.

No preservatives are used and there is no general scheme for recovering timber, only a small portion of which is reclaimed. The timber is delivered to the working places by locomotives and mules during the day shift, and placed by the miner as required. Table II shows the amount of timber per ton and per acre used for all purposes, including mine-car repairs, ties for mine roads, caps, props and miscellaneous:

TABLE II—TIMBER CONSUMED, BOARD FEET

Mine No.	Average Thickness of Seam, Ft.	Board Ft. per Net Ton	Board Ft. Per Acre
2	5.75	2.8	32,164
3	4.53	5.6	48,600
4	6.32	4.0	66,075
5	6.94	3.4	40,318
6	6.18	1.4	16,263
7	6.37	3.5	45,453
8	5.97	4.2	43,750
9	7.36	2.3	26,611
10	5.52	5.2	47,685
11	5.35	4.4	45,411
12	5.04	2.6	33,083
Average	6.06	3.3	38,163

Mine tracks and hauling equipment have been standardized. A gage of 48 in. is standard for straight track, 48½ in. on haulage curves, and 49 in. on room curves. The standard radii of curves and switches are 100, 150, 200 and 300 ft. for roads and 30 ft. for room turnouts. Rails are 60-lb. on main haulage roads, 40-lb. on room headings, and 20-lb. in rooms and temporary

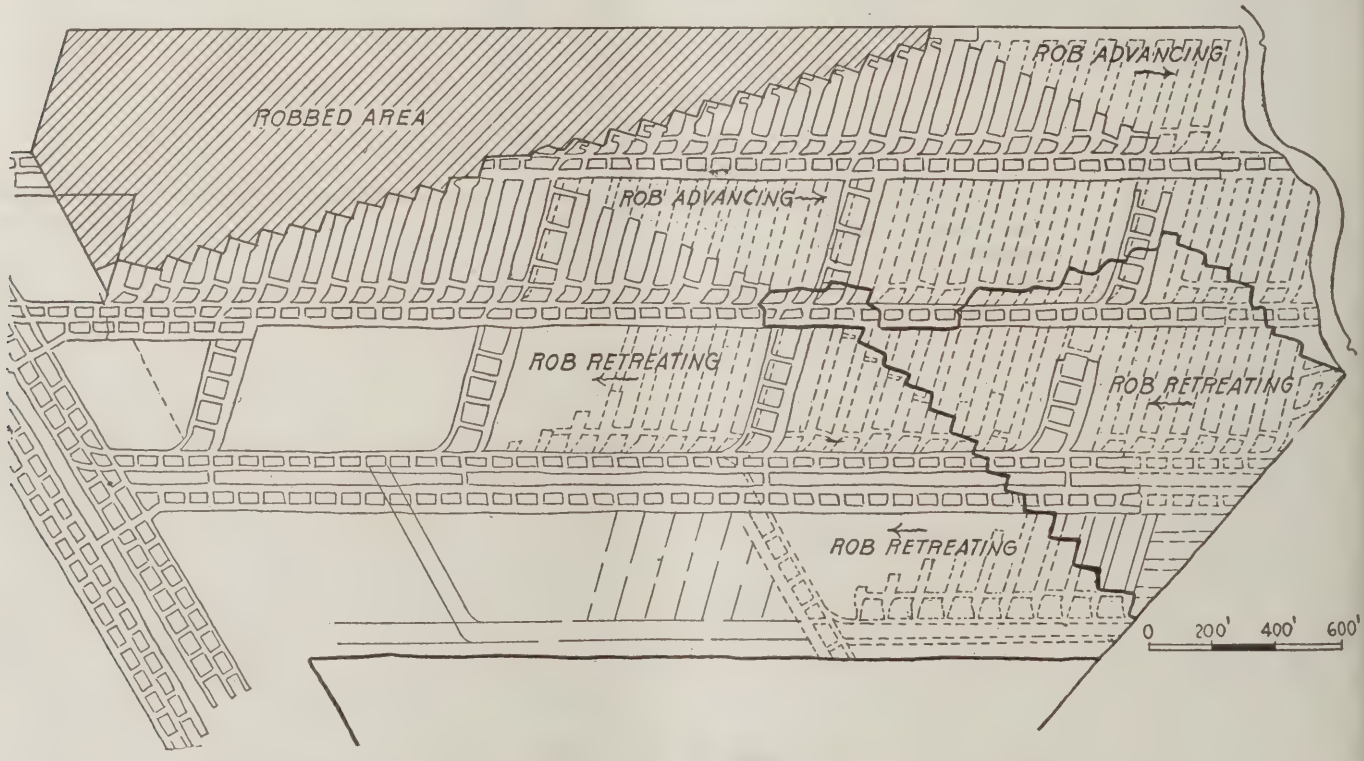

FIG. 6—GENERAL PLAN OF MINE NO. 6, UNITED STATES COAL & COKE CO.

Usually when rooms are driven and room pillars are drawn advancing the headings are maintained for years till their stumps and pillars can be withdrawn retreating. This withdrawal is in itself at times a matter of years. The presence of these heading pillars, necessary as they are, is to be regretted, for they divide the lines of fracture of the pillared area and, as has been said, the heading also has to be maintained for long periods of time despite the fact that it is subject to the excessive stress resulting from the fact that the coal on either side has been extracted. In contradistinction, in this method the headings at No. 6 Mine are provided with cross roadways so that the pillaring line can be extended to take in the heading pillars, approach being made to the heading thereafter by some one of the cross roadways. The main road, however, is kept well in solid coal and is mined retreating both as to rooms and pillars. With this arrangement the tonnage is maintained both on advance and in retreat. With thick coal the cross roadways are constructed at little cost.

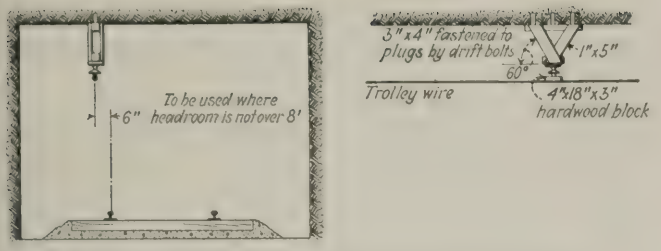

FIG. 7—STANDARD TROLLEY SUSPENSION FOR AN 8-FT. HEADING

The track is set 6 in. further from the rib than the line of the trolley. The bracket, being braced, does not work loose despite its projection from the roof.

headings. The main haulage road is double tracked and has no grade in excess of 2.5 per cent. Before any permanent track is placed on the main or branch haulage roads, a profile is made and it is graded according to elevations.

Room track is placed and maintained by the miners; all turns and switches are placed by company men. Ties 5½ in. x 6½ ft. are used under 60- and 40-lb. steel rails; ties 4½ x 5 in. x 6 ft. are used under 20-lb. steel rails, where conditions do not warrant the use of steel ties. On haulage roads, ties are spaced not over 24 in., and steel ties for temporary track are spaced not less than 36 in. In headings the temporary track is torn up, graded and

TABLE III—LABOR EFFICIENCY

	Tons Per Man-Hour	Man-Hours Per Ton
Miners in headings, including machine runners, (best miners usually assigned to headings)	2.115	0.463
Miners in rooms, and at pillars, including machine runners	1.870	0.534
Miners on slate or rock work (estimated)	2.500	0.400
All miners	1.910	0.523
All underground day labor	1.850	0.540
Men on transportation system	5.570	0.179
All surface labor, excluding office force	3.380	0.295
Total organization, excluding general office and engineers	0.728	1.365

laid permanently at such intervals that the end of the permanent track is never more than 150 ft. from the face.

On haulage roads the minimum clearance from any part of a locomotive or car is 2½ ft. on each side, and the least vertical distance is 5½ ft. above the top of the rail. Where grades exceeding 2 per cent are encountered, the floor or roof is excavated to allow as favorable a grade as possible. Room headings are on an average grade of 0.5 per cent in favor of the loads.

No side tracks, or partings, are required by the system of transportation in use. Mules are used only for hauling cars into and out of the working places, and hence can serve a larger number of places with less work than under a system involving side tracks.

The locomotive enters the room heading, pulling a trip of empty cars, which are distributed at the mouths of the various working places by disconnecting them from the rear end of the trip. At the same time it pushes together the loaded cars placed on the heading by the mules, until its trip is assembled. The motor then passes through a haulageway to a parallel heading and thence in

TABLE IV—CLASSIFICATION OF DAY LABOR

	Per Cent		Per Cent
Inside Labor:		*Outside Labor:*	
Mine foremen	0.60	Clerks	1.26
Fire boss	0.16	Janitors	0.09
Assistant mine foremen	6.13	Stablemen	0.94
Roadmen	9.27	Teamsters	2.06
Day labor	22.70	Garbage men	0.45
Bratticemen	1.29	Laborers	4.85
Wiremen	1.36	Labor foremen	0.48
Pumpers	0.78	Pumpers	0.77
Drillmen	0.19	Electricians	0.93

		Painters	0.15
		Sanitary inspectors	0.07
		Total outside day labor	36.16

the direction of the tipple; these haulageways from the main heading to the room heading are driven at intervals of 800 ft. (See Fig. 6.)

Usually a 13-ton electric locomotive will gather from the mouths of the working places and deliver to the outside 600 to 700 tons of coal per day when the round trip does not exceed four miles. From five to seven haulers and seven to ten mules, depending upon the grades in the working places, are required to gather the coal hauled by one locomotive.

Wooden mine cars of 93 cu.ft. capacity are used. The axles are 3 in. in diameter and run in plain bearings. The wheels are of cast iron, 18 in. in diameter and run loose on the axle.* The wheelbase is 48 in., the same as the gage.

In 1921 each car made an average of 1.7 trips per shift. At that time 508 mine cars were in service at this plant. At present the average is over two trips per shift. In 1919 each car traveled an average of 878.4 miles loaded, and made an average of 507.7 round trips, the average haul at that time being 1.723 miles each way; it thus performed 3,039 ton-miles of work. In 1921 the cost of mine-car maintenance per ton was $0.0422, of which amount $0.0179 was for labor and $0.0243 for material.

Four 13-ton electric locomotives and one 26-ton tandem locomotive are used for all gathering and main-

*Steel wheels are now being used.—EDITOR.

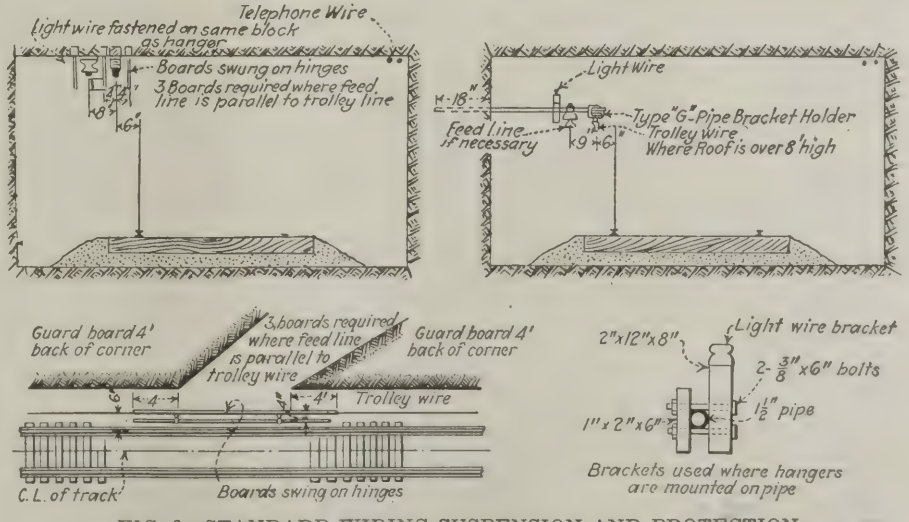

FIG. 8—STANDARD WIRING SUSPENSION AND PROTECTION

Where the roof is high the wire is suspended from a horizontal arm which carries also the electric line for lights, the feed cable, if any is needed, and the trolley wire.

TABLE V—SCALE OF WAGES FOR DAY LABOR; LATE IN 1922

Occupation	Per Hour	Occupation	Per Hour
Stableman (per month)	$145.00	Laborers, inside	$0.70
Teamsters	0.60	Haulers, inside; mule	0.80
Carters	0.55	Motormen	0.80
Mason tenders	0.55	Boss drivers	0.95
Outside laborers	0.40	Motor brakemen	0.84
Chargers	0.75	Loaders under tipple	0.70
Charger trailers	0.60	Dumpers	0.70
Car shifters	0.55	Car catchers	0.65
Draughters	0.55	Car pushers	0.65
Oven waterers	0.55	Car droppers	0.70
Coke machine boss	0.65	Pumpers, inside	0.75
Outside pumper and pipeman	0.65	Checkman	0.65
Watchman	0.55	Tipple foreman	0.94
Substation man	0.60	Greasers	0.60
Crusher repairman	0.65	Picking-table men	0.55
Blacksmith	0.90	Slate dumper	0.55
Slate picker	0.55	Bratticeman	0.80
Assistant mine foreman	0.95	Wireman	0.80
Shop foreman	0.90	Motor repairman	0.85
Machinists	0.90	Mining-machine repair man	0.85
Carpenters	0.80	Masons	0.80
Car repairman	0.90	Machinery inspector	0.85
Roadmen	0.89	Firemen	0.75

haulage work. The four smaller locomotives frequently handle as much as 875 tons apiece; their average for 1921 was 612 tons each per shift. The tandem locomotive hauls from 1,662 to 1,750 tons per shift, with a maximum haul of 12,000 ft. The most advanced workings are 17,000 ft. from the tipple.

The company employs no so-called contractors; miners and machine runners are paid on a piece basis, and loaders on a car basis (Table VI). Day labor is paid by the hour (Table V).

Table III gives the output, in tons per man-hour, based on records for May and June, 1922, when 1,027,795 short tons was produced.

While no satisfactory records are kept from which the percentage of labor turnover can be figured, it is believed to be small as compared with other mining communities. Many of the employees have been working for the company 15 to 18 years. The superintendents employ all men and discharge them for defective work. Mine foremen have authority, under the state mining law, to discharge for infraction of the mining laws.

Table V gives the wage scale in force at the close of 1922, for miscellaneous day labor, mostly on the outside; the length of the shift is 9 hours.

Table VI gives the coal mining and loading prices in force at the close of 1922. Miners in this occupation usually work about 8 hours a day.

Table VII gives the consumption of power during May and June, 1922 when the total production was 1,027,795 net tons, the figures including all transmission, transformer, and conversion losses. In Table VIII is given the cost of power, per ton mined for various purposes.

Table IX distributes the cost of material and supplies not previously included in the cost of power; the percentages are based on the total cost of these materials, not on the total cost of production.

Safety is the first consideration in all plans of organization, mining, construction, installation and operation. Specifications for all machinery must call for proper guards before quotations are requested. A standardized system of mining was devised as the best means of reducing the hazards of the work; the standard clearance on all headings and standard timbering in all rooms, as well as the removal of all slate in the headings, are among the most efficient provisions that have been adopted. Premiums are paid monthly to underground foremen for good accident records.

Frame dwellings are provided, all of which have electric lights in every room. Artesian wells have been drilled to supply water for all purposes, and the water is filtered. Running water is piped into all houses, and

TABLE VI—COAL MINING AND LOADING RATES; LATE IN 1922

Machine Rates		Coal Loading Rates, Per Car	
Room up to 24 ft., with 8-ft. cutter bar, or less:			
Runner	$1.70 per place	Room	$2.00
Helper	1.30 per place	Heading	2.12
Room over 24 ft., with 8-ft. cutter bar, or less:		Wet heading	2.15
Runner	$1.90 per place	Mining and loading by hand (pick)	2.10
Helper	1.55 per place	Slate	1.80
Room up to 24 ft., with cutter bar over 8 ft.:		Black rash	1.15
Runner	$1.80 per place		
Helper	1.50 per place		
Room over 24 ft., with cutter bar over 8 ft.:			
Runner	$2.30 per place		
Helper	1.85 per place		
Room over 45 ft., with cutter bar over 8 ft.:			
Runner	$2.45 per place		
Helper	2.00 per place		

TABLE VII—POWER CONSUMED, PER TON AND TOTAL

	Kw.-Hr. Per Ton	Total Kw.-Hr.
Cutting	0.25	256,949
Hauling	0.77	791,402
Pumping (inside)	0.138	141,836
Pumping (outside)	0.613	630,038
Ventilating	1.372	1,410,135
Tipple machinery	0.225	231,254
Lighting (outside)	0.3	308,339
Lighting (inside)	0.075	77,085
Shop and miscellaneous	0.2044	210,037
Total	3.9474	4,057,075

a drain system is provided. A number of the dwellings have baths and other modern conveniences.

Concrete and macadam streets and concrete sidewalks are laid on the principal streets, with concrete walks to the front and back doors of many of the houses. The Americans, both white and colored, and the foreign employees live together in harmony in these towns; the only segregation requirement is that white and colored shall not live in the same house. Churches for white, colored and foreign employees are situated at the company's plants.

Separate schools, managed by the district board of education, are provided for white and colored employees; these are rated as "First Class" by the State Department of Free Schools. The smaller children are taught at local schools, close to their homes, while junior and senior high schools are centralized at five

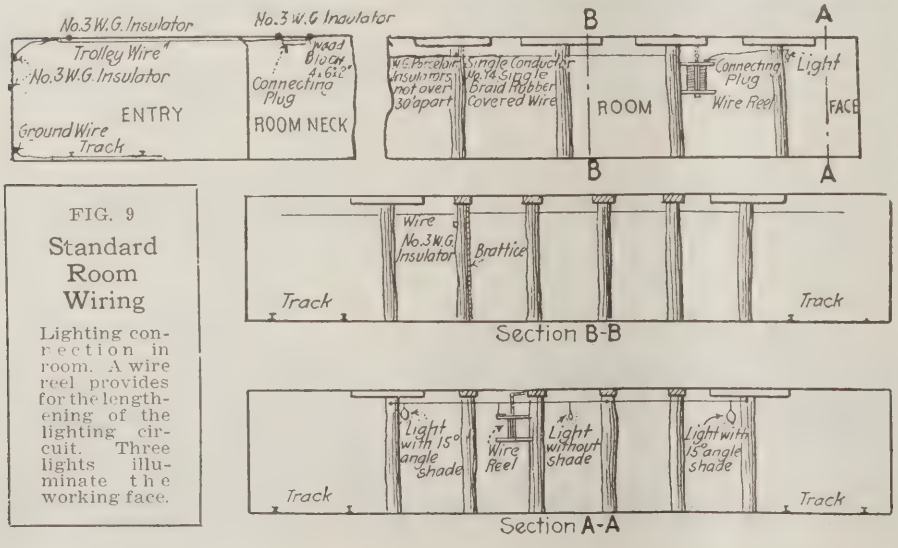

FIG. 9
Standard Room Wiring
Lighting connection in room. A wire reel provides for the lengthening of the lighting circuit. Three lights illuminate the working face.

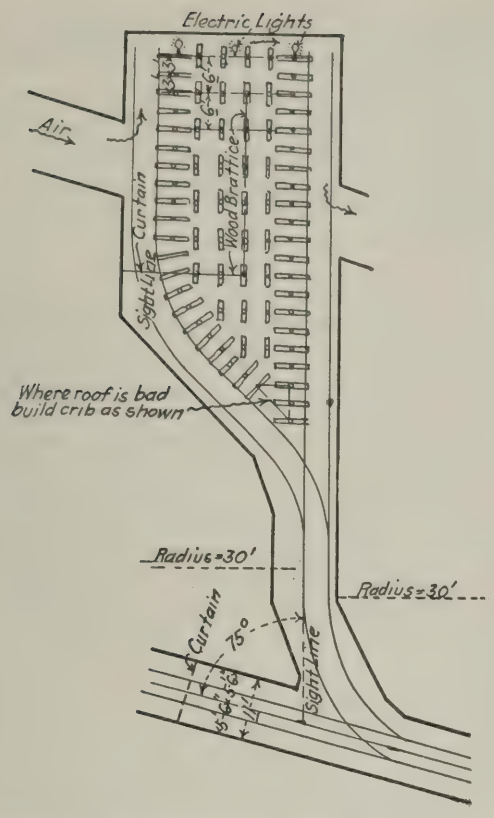

FIG. 10—STANDARD TIMBERING FOR TWO-TRACK ROOM

Where necessary temporary posts are set to protect the men while loading coal. The foremost posts are never more than 6 ft. from the working face. The distance from the rail to the outside of the posts is 24 in. on straight track and 30 in. on curves. Track is maintained on both sides of the room. When rooms exceeding 36 ft. in width are permitted the extra width must be put between track centers and the distances between props must be changed accordingly, the same number of these supports being used. In wide places where the top is bad cribs should be built.

different points on the plants of the company; the larger children are carried to school in automobiles during the entire school year. Gary High School is an accredited entrance school for the University of West Virginia and several other universities of equal standing.

Amusements are provided by motion picture theaters, bowling alleys, pool rooms, baseball grounds, tennis courts and the various athletic clubs. All employees can participate in these amusements. Club houses are provided among the various plants of the company, in which board and lodging are provided for the single employees and such married people as do not care to keep house. These club houses are used also for community gatherings. The recreation of the younger people generally is conducted under the auspices of the church or school authorities.

TABLE VIII—DISTRIBUTION OF POWER COST, PER TON MINED

Mining	$0.00250
Hauling and hoisting	0.00995
Pumping	0.00138
Ventilation	0.01372
Shop and miscellaneous	0.01192

Provisions, household necessities, etc., are supplied through an affiliated concern, the United Supply Co., which conducts a mercantile business at eight different points, in and around Gary. Each store has seven departments. As the stores purchase their goods in large quantities for cash, and their business is conducted on practically a cash basis, their prices to the consumer, after allowing for a fair profit, are lower than those of merchants in surrounding towns, such as Welch, Wilcoe and Anawalt.

TABLE IX—DISTRIBUTION OF COST OF MATERIALS

	Per Cent		Per Cent
Mine roads	18.66	Cleaning, crushing and washing coal	0.25
Mine cars	8.45	Fire protection	0.06
Haulage system	14.65	Other machinery repairs	0.50
Hoisting and dumping	1.00	Safety	0.06
Shaft, tipple and bins	0.31	Welfare	0.13
Ventilation	3.57	Miscellaneous	4.83
Drainage	1.31	Electric lights	2.88
Machine mining	4.45	Pit posts, caps and crossbars (3.3 board ft. per ton)	24.49
Explosives (0.117 lb. per ton)	1.31		
Horseback, rock and refuse	0.25		
Live stock	10.65		
Lubricants	2.19		100.00

Ground is rented by the United States Coal & Coke Co. to outside parties for running stores, devoted principally to the coarser grades of merchandise, such as feed, flour, etc., delivering to the purchasers by trucks. All employees are paid in cash and they are under no obligation to trade at any particular store.

A nurse has been employed by the Board of Education and the local chapter of the American Red Cross. This nurse visits the schools and examines the children, particularly for physical defects, but also for cases of malnutrition and other matters affecting their health. A dental clinic is provided by the county. The dentists visit each school, examine the children's teeth and do such dental work as is necessary; all without charge to the parents.

Can Electrical Detonators Be Fired by Stray Current and What Is the Cure?

AS THE result of an accident which happened at the Birdseye mine of the Hudson Coal Co., in the anthracite region of Pennsylvania, last November a conference was called by the State Department of Mines to investigate the possibilities that shots may be exploded prematurely by stray currents passing through their electric detonators. The meeting, which was attended by representatives from the anthracite mining companies, the powder companies, the street railway companies, the state department of mines and the U. S. Bureau of Mines, was held in the office of the Glen Alden Coal Co. at Scranton, Feb. 21, District Mine Inspector Evans acting as chairman.

Investigations made after the Birdseye accident indicated that after the wires were connected to the leads of the detonator and while the men were leaving the working place, the charge by some unknown means was discharged. The tests made by the Hudson Coal Co. showed stray currents in the mine. In fact, a voltmeter test showed 12 volts between a drill in the coal and the rail of an unbonded track nearby. In some places readings as high as 4 volts were taken between two drills on the coal. No ammeter readings were taken.

Doubt was expressed whether with such voltages enough current would flow to fire a detonator. A powder man stated that only with a current of one-fourth of an ampere or even more could a detonator be fired.

As a precautionary measure the Hudson Coal Co. is trying out a duplex rubber-covered wire for shotfiring. It is hoped by this means to eliminate the possibility of the lead wires picking up stray currents or of coming in contact with charged wires or open joints in the track.

No positive conclusions were reached at the meeting, the matter being laid over for future discussion and investigation. In the meantime those interested will make investigations of their own to supplement the work of the committee.

Precautions Taken to Guard Men from Seam Outbursts

Drillholes Serve to Reveal Danger but Are of No Value for Removing Gas—Limitations of Driving Rate—Jarring Shots to Provoke Outbursts—Means of Rapid Escape When Blowouts Unexpectedly Occur

By F. C. Cornet*
New York City

IN ORDER to protect the miners against the disastrous effects of blowouts, which occur so frequently in the deeper seams of the Belgian mines, it early became the general practice in such workings to drill the face with boreholes so as to drain out the gas contained in the seam. This practice long ago was found to be utterly ineffective, a worthless and illusory precaution.

Before the workings had penetrated into the seams now classed in the third category, which includes all beds subject to blowouts, boreholes only rarely produced any violent emission of gas and fine coal. The miners termed these rare manifestations "volcanoes" (*volcans*). It was believed that they resulted from the drill running into a pocket where gas was confined under high pressure. Although sometimes violent enough to throw the drill out of the hole and far to the rear, "volcanoes" generally were of short duration, causing fatalities only when the gas was ignited at a broken safety lamp.

Deeper Boreholes and More of Them

As operations entered more deeply into the seams subject to blowouts, volcanoes became more and more frequent and assumed a more and more vicious character. Deeper auger holes and more of them were prescribed, the idea continuing to prevail that after the holes had liberated the gas held in the empty spaces of the seam the latter were safe to a depth at least equal to that reached by the auger. An occasional volcano was thought to make conditions safer still. Therefore great was the surprise of management and men when it was shown repeatedly by experience that faces well drilled and supposedly well drained of gas would blow up without any warning other than that of the underground thunder and crushing of timbers to which the men had been accustomed in seams at a higher geological level, including those in which no gas is ever found.

Slowing Progress to Reduce Accidents

Several companies that were working the lowest seams that at that time had been reached conceived the idea that the rate at which the workings were advanced should be restricted, and when they applied that method they were rewarded with a certain degree of success. It was not, however, until 1879, after the spectacular Agrappe blowout that the Belgian Department of Mines formulated and made compulsory a comprehensive system of regulations concerning boreholes and a limitation of the driving rate in all mines subject to these manifestations (*dégagements instantanés*).

As most of the boreholes ceased to show any sign of gas after they had released what was contained in the cleavages and other empty spaces which they traversed the miners frequently attained a false feeling of security. This assurance still continues to some extent, despite the many blowouts that have occurred after the auger has revealed no conditions of a dangerous nature. But if, for seam-drainage purposes, holes drilled through what I have designated as safe coal are absolutely inadequate (for reasons previously explained) the fact remains that as a means of detecting a crushed zone lying ahead in the solid no substitute has been so far found for them. The same may be said of their use in *bouveaux*,* where they constitute the only means of ascertaining how near is the seam ahead. Even when the formations are regular, the engineer in charge seldom knows with an approximation closer than 5 or 8 ft. where the next seam will be met. In the highly disturbed territory to the south of the field it is nearly impossible to tell within 30 or 40 ft. how close the nearest seam is. Worse yet, the *bouveau* may miss the seam entirely, passing clear above or under it, to meet it perhaps only where it next turns upward or plunges downward as the case may be.

When workings proceed through hard or comparatively hard coal (meaning coal that, after being undercut requires wedging or picking before it will fall away from the face) the conditions as a rule will remain reasonably safe so long as the auger holes driven ahead reveal no marked decrease of coal cohesion and provided the daily rate at which the faces are driven be not too great.

Danger of Sudden Discovery of Crushed Coal

We have seen in the previous article† how a zone of unsafe coal may be close ahead, although still unrevealed by the auger holes, so close indeed that the advance of the face in the course of a single working shift may reduce the resistance of the barrier of safe coal till it no longer can oppose the expansion of the coal in the unsafe zone ahead. This causes the crushed coal to blow out into the workings in such a manner as to imperil the lives of the employees. Too rapid driving may cause this barrier to break down without the boreholes affording any indication that such a catastrophe is about to happen.

No matter how safe the driving rate adopted may seem to be, the advance work at the face must be distributed over as great a part of the working shift as will be found practicable. The work also must progress evenly from end to end of the face. When, as is generally the case in Belgium, several faces arranged in a group advance together into the seam, one should not be driven any faster than another. Suppose, for example, the driving rate adopted is 4 ft. a day and the working shift is of 8 hours' duration. To advance the whole 4 ft. during the first two hours of the shift

*Consulting engineer.

*Tunnels through rock driven to connect a shaft with pitching coal seams.

†"Blowouts in Belgian Coal Seams and the Way in Which These and Like Phenomena May Be Explained," *Coal Age*, March 1, 1923, pp. 367-372.

instead of distributing the work over, say, six hours, would be equivalent to a driving rate of 12 ft. per day instead of 4 ft.

To form an idea of how difficult it is to tell what is a safe driving rate, it is only necessary to point out that it varies from seam to seam, that it depends on the condition of the strata, including, of course, the seams themselves, and that even in a given seam it varies with the cohesion, pitch and regularity of the coal. For example, a certain driving rate which may be perfectly safe at a distance from a fault, syncline or anticline may prove positively dangerous in the neighborhood of such a geologic disturbance.

Experience Suggests Safe Driving Rate

A rate that may be safe in a strongly pitching part of a seam may be so no longer where the seam is flatter, or vice versa. With known seams, or rather, groups of seams, the safe driving rate under varying conditions may be determined from past experience, care being taken to give safety the benefit of the doubt whenever there is any uncertainty. When first reaching a group of seams at a new and lower geological level, the engineer always meets conditions more difficult to control than any he encountered at higher levels. But if he is really experienced and conservatively inclined he will find, eventually and without unnecessary loss of life, a rate of driving that is reasonably safe.

No matter how safe the driving rate may be, the day always will come when an area will be approached for which that rate will not afford the desired safety. Nevertheless even then the slow driving rate usually will save the day, for, fortunately, as long experience has shown, the familiar cracking of timbers, first wind and underground thunder precedes the collapse of the face by a longer period when the rate of driving has been conservative than it does when the rate has not been so limited. This is of great importance, for men have been known to lose their lives because they lacked a few seconds of time in which to turn a corner or drop down a rope to the gangway below.

Last Ten Feet Driven Without Explosives

Until recently it was provided that when a *bouveau* was shown by a drillhole to be 10 ft. from a seam, nine other holes were driven to reach the coal, whatever that distance might be. After this all work was suspended for 48 hours. This was in conformity with the old idea that the boreholes would drain the gas from the seam, making the latter less likely to blow out when the *bouveau* would finally approach, reach and pierce it. The rules provided that explosives might be used in driving *bouveaux* until the face was found to be within 10 ft. of a coal seam. Thereafter the passageway had to be driven without the aid of explosives until it was once more in the solid rock beyond the seam.

Mining men accustomed to tunneling through slate and sandrock will be able to imagine what it costs to drive that length of *bouveau* without the aid of explosives, using only a drill, wedge, pick and sledge. The examples I have given and the facts I have related in a previous article regarding blowouts in *bouveaux* do not indicate that the restrictive measures imposed for over 40 years on *bouveau* driving had much success. It is a fact that this kind of work was considered so risky that it always was difficult to get men to do it, even at a large increase in pay.

A policy radically different at last has been adopted by the Belgian Department of Mines. Not only are explosives allowed in driving the 10 ft. separating a *bouveau* from a seam but no limitation is put on the number of shots that may be fired simultaneously, provided no individual hole contains more powder than the limiting charge for the explosive that is being used.

Ten to twenty holes, depending on the nature of the strata traversed, are fired together from a safe place when none but shotfirers are in the mine. This blast is called the "jarring shot" (*tir d'ébranlement*), for the reason that its purpose is to shake the strata, including the seam, sufficiently to provoke a blowout and to cause it to occur then and there, if conditions are such that one is likely to happen.

The result of this more liberal policy on the part of the Belgian Department of Mines has been evident from the beginning. The new practice has been in operation for thirty months. In this period hundreds of blowouts have been willfully provoked in *bouveaux* and none has caused so much as a scratch to anyone. The material damage has been less in aggregate than would have been done had the blowouts been allowed to occur naturally, as they would certainly have done had they not been made to take place at the operator's own appointed time.

Eleven Blowouts in a Single Bouveau

In the Mons District between July, 1920, and December, 1922, a *bouveau* was driven a horizontal distance of 2,700 ft. through the lowest group geologically of all those which so far have been reached and operated in Belgium. The *bouveau* passed through sixteen seams in that distance. In eleven instances a blowout resulted. The longest time elapsing between the blast and the blowout was 17 minutes. The five seams that did not blow out were hard at the point where the *bouveau* intersected them, which explains why, although fully as gaseous as the other seams, they remained passive.

The jarring shot was adopted more than twelve years ago in the Gard coal field of France, where the practice is permitted in all parts of the mines instead of being limited, as in Belgium, to *bouveaux*. In the latter country explosives may not be used in and about the coal workings of seams of the third category. Signs abound, however, that Belgian operators will not be satisfied till they also are allowed to produce blowouts at the coal face by shots fired from a safe distance when nobody is exposed to the consequences of any gaseous manifestation that may occur.

With the new methods boreholes are not necessary except for the placing of shots. Moreover, the driving rate ceases to have any importance and may be as great as the operator may find practicable. Shots placed in the coal in sufficient number and so located that their operation will shake the whole face or group of faces operated are fired simultaneously or in series and in rapid succession. The firing is done electrically from a safe distance in the mine by two experienced men, after all other miners have gone home for the day.

When the men arrive in the morning all they have to do, besides loading the coal thrown out by the blast, is to set all necessary timbers and drill new holes in the face. The miners are strictly forbidden to cut into the face with a pick. If the blast of the previous night has left some fissures in the face and some coal looks as if ready to fall out, these conditions must not be disturbed. What one night's blast has left unfinished

must be left for the blast of the following night to complete.

It is easy to understand that when a zone of dangerously crushed coal is critically near, the shots will demolish the barrier of safe coal, which prevents that decrepitated material from expanding into the workings or will so weaken it that it will hold out only for a short time. One interesting example among many similar ones will be cited to show how really preventive is this method:

In a single year in a single seam in the Molière Shaft at Bessèges (Gard, France) forty-four blowouts took place, all of which resulted from shattering blasts fired at night. None occurred otherwise, and not one of them killed or injured anyone. In the whole Gard District not a single man has been hurt by a blowout since Nov. 15, 1912, when, as a result of disobedience to most positive orders, one of the shotfirers, impelled by curiosity, ventured into the workings 10 minutes after the blast, when a blowout took place, by which he lost his life. Although when a blowout is about to occur it generally does so promptly, that is, a few seconds after the shattering blast, it sometimes happens only after several minutes. In at least one instance 20 minutes of delay was noted.

Not a single inflammation of gas or dust has been recorded as yet as the result of a shattering blast. The fact that only safe explosives safely used are permitted in the operation is not enough to account for this freedom of ignition, which must be attributed mostly to the impossibility of the eruption of dust-laden methane taking place simultaneously with the blast. It is the latter that causes the former. Hence they cannot be simultaneous. In a procession of phenomena of this kind an interval of one second, the shortest ever recorded, is considerable compared with the rapidity with which a shot explodes.

French Use Shattering Blast at Coal Face

The French did not apply the shattering blast to seams subject to blowouts of methane gas until after they, successfully and for many years, had made use of the same process to provoke outbursts of carbon dioxide in coal seams where this rare kind of gaseous manifestation occurs. These outpourings of carbon dioxide in some mines had happened on many occasions most unexpectedly and had caused the death of many miners. It was natural for the French to think of applying in the case of methane a remedy that had proved efficacious with carbon dioxide, bearing in mind, of course, that the latter being inert while the former is most inflammable precautions must be taken with the one that would be superfluous with the other. As soon as the French Department of Mines became reasonably convinced that with permissible explosives the shattering blast was not likely to prove dangerous in seams subject to methane blowouts, they so advised the Gard operators, who lost no time in taking advantage of the permission to use that method. The results have been explained above.

So far as Belgian mines are concerned, there is no doubt that they will soon be allowed to follow the French example. All they are waiting for is the raising of the embargo put by the Mines Department on the use of any kind of explosive at or near the coal face in mines of the third category. There is no reason why a method which is good to the south of a boundary line should not prove valuable also to the north of it.

So much for "offensive prevention," as the method of jarring the coal by shots is termed. As has been said, Belgium still uses defensive prevention everywhere but in *bouveaux*. The precautions thus characterized now consist solely in a limitation of the driving rate. A daily advance of 4 ft. is exceptional in Belgium. As already stated, the 4-ft. advance should be distributed over not less than six hours of the eight-hour shift. At least three separate cuts are made, each being loaded into cars before the next one is started.

Under such conditions machine cutting as understood in the United States hardly can be considered in Belgian mines of the third category. In the case of the offensive-prevention method described, any kind of cutting by machine or by hand, is contrary to the very principle of the process. The shattering blast unfortunately produces much slack coal mixed with slate so small that it can be eliminated only by washing.

Precautions in Case of Unprovoked Blowout

I must pass on rapidly to the precautions taken to avoid, or at least minimize, the loss of life when a blowout occurs. To explain these precautions fully would nessitate going into details of a rather complicated sort concerning the many working methods followed in Belgian mines of the third category. As there are numerous variations of these methods made to suit the different conditions in which the seams are found, I must be satisfied with generalities if this paper is to be kept within permissible limits.

The faces always are so arranged in relation to each other and to the main gangway at the base of the workings that the men will find it possible to leave the workings promptly even if the lamps are blown out by the first wind. The escape of the men working along the face in the block of coal directly above the main gangway is comparatively easy even in darkness. Not so, however, with the men working at the other faces, for they must find their way not only down two or more faces but also from face to face through the connecting place called *bourre* by the miners of Belgium.

To make escape easier the faces are as few in number and follow each other as closely as possible. In other words, the engineer in charge tries to keep the general face line as straight as he can. When a man making his way out in darkness arrives opposite the *bourre* at the bottom of a face, he runs into a 2-in. manila rope to which bells are attached. He follows the rope to the next face, and so on. Men going out like this in succession keep the bells jingling, thus giving precious indications to those who may have lost their presence of mind as to the direction in which to proceed.

In workings steep enough to make the use of ladders necessary, there always is next to each ladder a rope by which the men may lower themselves quickly. By merely touching this rope a string of bells is set jingling. Sometimes, where the grades do not justify ladders but yet are steep enough to permit of this arrangement, narrow places are maintained in the gob in which troughs made of sheet steel are laid on the floor of the mine. Down these the men slide directly to the main gangway. This roadway is straight and high enough for big horses, so that once there the men make rapid progress to the *bouveaux*.

There is always the possibility, however, that the men may be delayed in their passage through the main gangway, as also in the workings above, by roof falls or by rocks thrown out of the floor in the manner

described in the previous article. When the *bouveau* is reached, comparative safety is in sight of the men, but even here there still are chances of their being either thrown down and incapacitated for further flight by the second wind or overtaken and smothered by an avalanche of dust traveling toward the hoisting shaft. This happened not only in the historic Agrappe blowout but in many other instances.

What I have designated as comparative safety consists in a string of cells dug in the solid rock ribs of the *bouveaux* at intervals of about 80 ft. These cells, made when the *bouveau* is driven, are entered through a door opening inward. Two storage-battery lamps independent of each other continually light each cell. In a small niche in the opposite side of the roadway two more storage-battery lights and two safety lamps are kept burning at all times. A window in the cell door of wired plate glass 4 in. square enables the men in the cell, even though the door is closed, to obtain a good view of the lights in the niche.

The door is provided also with a small hinged valve opening outward with great facility, but normally kept shut under its own weight. Finally, in a corner of the cell a 3-in. globe valve has been placed, closing the end of a branch of the main compressed-air line by which motive power is supplied to the pneumatic drills at the face of the *bouveau* and other workings, for these are everywhere in use. The main air line is kept under pressure at all times.

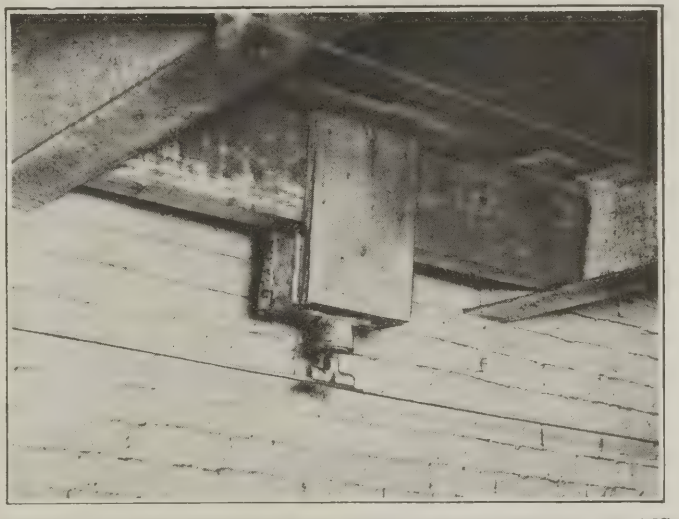
The men fleeing down the *bouveau* distribute themselves among the different cells to await developments. If the alarm that made them run out of the workings fails to be followed by a blowout, the men do not stay long in their cells. They are soon found at the shaft clamoring to be hoisted.

Do Not Return Till Face Is Inspected

Under no consideration may they go back to their working places before these have been inspected by the engineer in charge and his assistants. If the expected blowout fails to occur the men stay behind the closed doors of the cells until the fury of the gaseous manifestation has passed, anxiously watching in the meantime the safety lamps in the opposite niche. If these lamps go out, indicating a vitiated atmosphere in the *bouveau*, the 3-in. globe valve is opened admitting air to the cell in any volume necessary to make the atmosphere respirable. All excess of pressure is relieved automatically through the hinged valve in the door.

The electric lights, of course, do not go out. Besides serving to direct the men to the cells they have on countless occasions permitted those who had already reached safety to make quick sallies from the cells to rescue other men who had fallen in the roadway. The men are instructed not to leave their cells should the safety lamps in the niches go out, but to remain there until the atmosphere of the *bouveau* is shown to be safe by parties entering from the shaft. Nevertheless in only a few instances have the survivors of a blowout waited in their cells for the arrival of rescuers. Carrying the wounded and those too weak to walk, they generally start for the shaft as soon as they have reason to believe the air in the *bouveau* again has become respirable.

Tests Are Being Conducted at the experimental mine of the Bureau of Mines, Bruceton, Pa., for the purpose of determining the value of salt in conducting moisture to dry coal dust.



How to String Trolley Wire Below the Steel Cross Beams in Gangways

By Alphonse F. Brosky*
Pittsburgh, Pa.

MANY ways have been devised for carrying trolley wires under the steel collars or cross beams which support a haulageway. The problem is one often presented near or at the main bottom of a shaft mine. The way it was solved in the Criterion mine of the Westmoreland Coal Co., at Rillton, Pa., is illustrated in this article.

In this mine the steel sets extend 800 ft. and have been placed both on the loaded and empty sides of the big bottom. The cross beams consist of 10-in. I-beams placed on 4-ft. centers. They rest upon an 18-in. brick wall which extends along either rib. The roof is lagged with 4- to 6-in. poles which rest on the steel cross beams.

A wooden trolley hanger is inserted between each fifth and sixth beam, and to this is attached a trolley clamp of the timber type. The timber by which the hanger

METHOD OF SUSPENDING HANGER BELOW STEEL BEAMS
This hanger is easily placed and removed, and its height is easily adjusted at such a level that the trolley wheel will not rub on the collars or cross beams and, if dislodged, no arc will be formed through the head of the trolley arm.

is supported is a 4x8-in. plank of yellow pine to which two boards are spiked so as to project the required distance. A block is spiked between the boards so as to bear against the cross timber, this timber being wedged snugly between the beams and made secure to the roof by wedge blocks. All these details are shown in the illustration.

A hanger of this design has the merit of being held without nails, screws or bolts and therefore of being easily placed or removed. Furthermore, it can be assembled on the job, the correct height of the trolley wire being maintained by regulating the length of the boards. The minimum clearance between the trolley wire and the lower flange of the steel beams is kept at 11 in., so that, should the trolley leave the wire, there will be no short-circuiting or flashing, as the wooden pole and not the harp of the trolley wheel or the trolley head will strike the wire. The minimum clearance between the trolley wire and a steel cross beam should be greater than the over-all length of the metallic head of the trolley arm.

Annual Meeting of Institute Makes Good Start in Its Inquiries Into Subsidence and Excavating Methods

Does Roof Tumble Till It Clogs or Come Down Shattered but Not Destroyed?—Is Simplicity in Coal Preparation Desirable or Possible?—Can Tests Be Made of Rope by Magnetic Methods?

By R. Dawson Hall *
New York City

SUBSIDENCE, coal washing, stream pollution, the operating methods and costs for labor and materials at the Gary mines, safety in hoisting, fire prevention and fire fighting furnished a good coal-mining program at the one hundred and twenty-seventh meeting of the American Institute of Mining and Metallurgical Engineers, held at the Engineering Societies Building, New York City, Feb. 19-22.

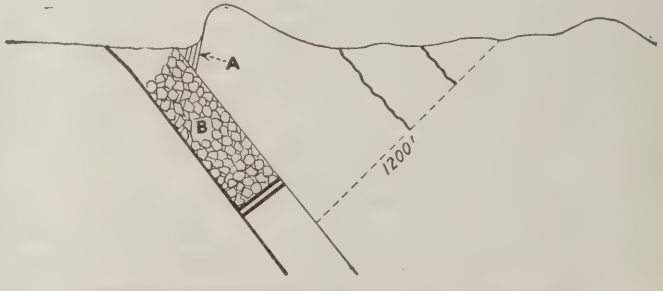
At the morning meeting J. Parke Channing described the subsidence at Miami, Ariz., and was followed by Howard N. Eavenson with an abstract of his paper "Mining an Upper Seam After a Lower One Has Been Extracted." Mr. Eavenson's paper appeared in full in last week's issue of *Coal Age*. In that article he successfully shows that the fears of the conservationists that the mining of a bed of coal would ruin all the seams above it and render them valueless were not justifiable by the facts. Still there were many who had been made aware of those facts many years back. Mr. Eavenson showed that the injury was so slight that he effectually confuted the notions of those who believe that the roof disintegrates into blocks which pile up and eventually fill up the excavated area. George S. Rice is not altogether exempt from this point of view, as his article showed.

Dome Theory Lives Long and Dies Hard

Advocated by such capable experts the belief dies hard indeed. The way the name Fayol passed from mouth to mouth showed how the primitive notions of that early investigator still had their devotees, and no wonder! Actions much resembling what Fayol describes actually happen and any mining man can see them. But the other breakages no one notes, for the line of fracture is unapproachable from below and may be invisible above, but the possibility of mining the beds above proves that what finally happens is not describable in the wording of Mr. Rice or of the long deceased M. Fayol. The roof does not, at least generally, break until it clogs itself.

The public owes a great deal to Mr. Eavenson for his practical paper. Hereafter it may not be necessary to send engineers scouting the country for data on this subject. Mr. Eavenson has settled the question once and for all.

J. J. Rutledge followed with a paper on "Subsidence in Southwest Coal Mines," in which he described the collapse of the mines at Adamson, Okla. He showed clearly that as a result of the catastrophe the ground was broken about 250 ft. ahead of the face of the workings, but as the mine was 750 ft. deep and as it dipped at 15 deg. the slope of the break was not much beyond the normal and rather to be expected therefore under all the older theories. Mr. Rice remarked that it was the only case of which he knew where a mine worked by rooms showed signs of collapse extending over the solid face, and he ascribed the action to the suddenness with which the breaks occurred. Dr. Rutledge also described the injury done to the Spring Valley schoolhouse which in the center rested on a heading pillar. The ends of the building extended over an area that had been first-mined but with pillars so small that the workings collapsed.



Mr. Rice's paper was accompanied by illustrations. He showed maps in which breaks to the surface coincided closely with excavated areas and did not extend beyond the limits of excavation. However, the contention of the advocates of "draw" is not that caving usually takes place, at least at first, beyond the limits of excavation but that fracturing and some tilting occurs beyond those lines, and this in the case of a plowed field may not exhibit itself on the surface. Moreover, where the opening extends to the top of the ground the failure usually is by vertical shear rather than by bending moment.

A French Roof Disregards Laws of M. Fayol

Eli T. Connor in his discussion said that at Essen, in Germany, where the seams had been filled by hydraulically placed material, the ground had sunk about 8 ft. as a result of the removal of 40 ft. of coal. At St. Etienne, in France, where the coal was on a 25-deg. pitch, the subsidence was 15 per cent of the total thickness of the seams worked.

George S. Rice said that at the Silesian steel works the underground excavations were filled with granulated slag which cements, and the subsidence resulting from mine excavations was only 3 in. Mr. Connor declared that granulated slag is not as strong as sand, as experiments of the Bureau of Mines had conclusively proved.

Thomas H. Clagett said that the damage to the upper seam is greatest at the first break and that the damage is slight if the break is carried steadily forward. J.

ILLUSTRATING EDWIN LUDLOW'S REMARKS

A mine working in a steep seam near Lansford, Pa., caused cracks to appear several hundred feet from the line of outcrop. Several drill holes were made in the hanging wall from the surface as shown at *A* and shots were fired, dislodging huge rocks which filled the workings at *B* and prevented any further cracking of the surface.

*Engineering Editor, *Coal Age*.

J. Rutledge declared that in northern Illinois the cracks at a mine were found to form in a limestone quarry above the mine 8 deg. 15 min. ahead of the working face. The mine was operated by longwall and over a long period of time the advance was only ½ ft. per day. The depth of the seam was 426 ft. below the point where the cracks were noted and the horizontal draws were 60 and 63 ft.

Edwin Ludlow described a weakening in the roof in a steeply pitching bed near Lansford which opened cracks along the planes of stratification parallel to the bed. This action manifested itself some 1,200 ft. from the bed extracted and tended to do further damage. (See Fig. 1). Large rocks were blasted off the nose, *A*, in the hope that they would fill the opening, *B*, and hold back the strata. To date this method has proved successful. Some fears had arisen that the town might be badly injured by the cracking of the strata.

Henry A. Buehler, state geologist of Missouri, Rolla, Mo., stated that in the longwall workings of northern Illinois described by Mr. Rutledge it was noted that the elevations of strata over the still solid coal increased about ¼ in. In the case of a single station this might be regarded as the result of an error in leveling but it was so general that another explanation must be sought.

Bumps Manifest Themselves at Lynch Mines

General Edward O'Toole remarked that at Lynch, 2,600 ft. of cover has been attained and bumps are beginning to occur. About 8 per cent of the coal is left behind, the pillars crushing under the load. It was noted that a stream was bled by the workings long before they extended to points beneath it. He added that it was found that the pressure was greatest when the pillaring line had advanced a distance from the point of first pillaring equal to about 1½ times the depth below the surface of the bed being worked. The mining methods meeting just described extended into the afternoon, lasting far longer than the time appointed for it.

In the evening the members met at a smoker, enlivened by a humorous address with lantern slides by Captain Walter E. Traprock on his alleged trip to the North Pole, by the singing of adaptations of popular songs prepared by D. E. A. Charlton and by entertainment furnished by Jack Armour, of the McGraw-Hill Co.

In the morning of the following day the Institute held its official meeting, electing E. P. Mathewson, president; T. T. Brewster, general manager, Mt. Olive and Staunton Coal Co., and F. M. Smith, vice-presidents, and the following directors: W. H. Aldrich, G. H. Clevenger, A. N. Diehl, Reno H. Sales and Seeley W. Mudd.

Secretary F. F. Sharpless reported on the affairs of the Institute. The operating loss on *Mining and Metallurgy* for the year 1922 was $9,307. The membership committee reported that the total membership, which at the close of 1921 was 10,205, had been augmented by 701 and decreased 1,493, leaving 9,413, of which, however, only 7,186 were members and 19 honorary members and the rest associate members and junior associates. The treasurer's annual report showed receipts of $177,013 and expenditure of $174,479.76. The assets totalled $696,965.05, including an equity in the United Engineering Society of $486,792.79 and books in the library of $40,000.

Vipond Davies discussed the affairs of the United Engineering Society by which the Engineers' Societies' Building is held. The land was purchased by the three Founder Societies each of which paid $250,000. Still later the American Society of Civil Engineers gave up its building and affiliated with the United Engineering Society, paying into the fund $250,000. The building was enlarged by two stories so as to accommodate the "Civils." The insured value of the library is $329,000, but the real value is much greater.

Parke Channing was called on to advocate support to the Federated American Engineering Societies, which he said was doing much to raise the civil status of the mining engineers. Charles F. Rand, the treasurer, said that the surplus after forty-eight years had reached the wholly inadequate figure of $40,000, which should be reduced by $17,000 because the proceedings for 1922 had yet to be published. This would leave only $23,000 for nearly a half century of effort. Other speakers were Arthur Dwight, the retiring president; A. H. Rogers, and P. M. Moore, relative to the discontinued relations with the National Research Council.

At the mining session General O'Toole read his paper on the "Pocahontas Coal Field, and Operating Methods of the United States Coal & Coke Co.," which appears in this issue of *Coal Age*. This is one of the first of the papers being sought by the mining methods committee. It gives the costs of units of labor and material in producing a ton of coal. At the conclusion of the paper S. A. Taylor, who is much interested in stream pollution, endeavored to elicit from the speaker the number of tons of water passing through the mine for every ton of coal mined. This General O'Toole could not state, most of the water not being pumped but led by a tunnel to the surface. Mr. Taylor declared that in western Pennsylvania the weight of water leaving the mine was about 7½ times as great as the weight of coal.

Want Simplicity and No Middle Product

E. A. Holbrook briefly recounted the points made in the valuable paper of Thomas Fraser and H. F. Yancey, entitled "Interpretation of Results of Coal-Washing Tests." J. R. Campbell, in praising the paper, said that the demand of today was for less elaborate washeries with less sizing and less auxiliary apparatus. Only two products were desired, good coal and refuse. Middle products, the operator found, were not profitable. G. R. Delamater said that he did not believe that one figure for efficiency could be obtained for the whole country but it was valuable to obtain such figures at any one plant as an index of improved or less efficient operation. He had been told that the capacity of by-product ovens had been increased 10 per cent by reducing the moisture content. This figure he said, seems unduly high but if correct it shows how important is a separation that will eliminate water.

Ralph H. Sweetser, assistant to the president of the American Rolling Mill Co., Columbus, Ohio, said that every per cent of ash above 6 per cent added 30c. to the cost of a ton of pig iron. Carl A. Wendell declared that two products were all that were desired. In England it had been found that the best size for washing was 1 in. It was difficult to screen sizes under $\frac{3}{16}$ in. where the coal was not dry. He believed that much might be said in favor of wet grinding to 200-mesh and amalgamation of the coal thus ground.

In the afternoon, M. W. Ditto delivered his paper on the "Design and Operation of the Roberts Coke Oven." He declared that the ovens, at times, had operated exclusively on the Franklin County coal, from southern Illinois, the product of the oven running only 1.35 per

cent sulphur. The oven was 14 in. wide at the narrow end and 15½ in. at the wider end. He did not believe that the success of the Roberts oven in handling Illinois coal lay in the narrow coking space, for he had coked the coal entirely from one side. The cell structure got coarser as it neared the far wall and the time was longer but the coal coked.

He believed that the secret of success in coking Illinois coal lay in the construction of the oven wall. About 4,200 cu.ft. of gas was obtained in the Roberts oven by coking a ton of coal containing 10 per cent of moisture. The time had been varied from 11 to 48 hrs. and the coal had coked in all cases, showing that the success did not depend entirely on the temperature of the oven.

His company had used the recuperator but he did not believe this to be necessary, and in future regenerators will be used. The Roberts oven uses interruption and impingement as a means of removing the heat from the gases. Hitherto, when seeking to get heats that will coke quickly, it has been customary to drive the gases through the flues at high speed. With interruption and impingement the speed can be cut down, reducing the water gage necessary.

Coking Time Has Been Reduced to 10½ Hours

Mr. Ditto added that the coking time on occasions had been cut to 10½ hrs. Nothing, he believed, would prevent the time being reduced to 9 hours, except that the brick may fuse if the temperature is made too hot in order to lower the coking time. On J. V. Freeman, of Joliet, Ill., asking the names of the mines furnishing coal to the Roberts ovens, Mr. Ditto said that the Old Ben Corporation, the Chicago, Wilmington & Franklin Coal Co. and the company's own Black Briar Mine in Williamson County had been among the sources.

Mr. Ditto said that the coke made in the Roberts oven is somewhat more free burning than that usually produced in byproduct ovens. He thought that the coke was somewhat lighter than the standard product and declared that the zone of combustion is smaller in furnaces using the coke and that accordingly the temperature at the mouth of the furnace is lower. Asked as to the possibility of cooling the Roberts oven without danger, he said that a second cooling seemed practically to wreck the oven. Carl A. Wendell said that he believed that further efficiency might be obtained if flues were run through the coal.

In a further discussion of the Fraser and Yancey paper Eli T. Conner remarked that the Chance separator had done excellent work, but that it had been found difficult to separate the sand from the sizes below ¼ in. It was hoped that better results on these fine sizes could be attained by the use of the Conkling separator, which relies on material of a finer mesh.

George S. Rice remarked that concentrating tables were not proving successful at the mines of the Granby Consolidated Mining, Smelting & Power Co., as the crushing of the coal by earth movement had made the product of the mine shell-like and not granular, resulting in as much as a 40 per cent loss.

Ray W. Arms stated that the air separator would treat coal running anywhere between 2½ in. and 150-mesh. At Raton an air separator is working on coal of 55 to 60-mesh. He did not believe that there was as much objection to fine sizing as some of the speakers had urged, especially with the air separator. Ten tables are often required to obtain the needed output. In consequence what extra expense other than the cost of screening was incurred in giving every table a separate size? Surely it was well to use several sizes and thereby attain maximum efficiency in preparation.

George S. Rice called attention to the danger of allowing the air of the tippie or "washery" to be filled with fine coal. It is true that an explosion will not occur where the particles are not so close that the burning of one will cause the combustion of another. Where dust collects on the tops of timbers and comes down in a stream, however, danger is imminent, especially where motors are working. If the timber surfaces are beveled or iron surfaces are sloped with cement mortar the danger is greatly reduced.

An article by Andrew B. Crichton, of Johnstown, Pa., was then presented, its subject being "Mine-Drainage Stream Pollution." In discussing it Mr. Taylor said that there was much danger that legislation to prohibit the dumping of oil within the three-mile limit might be passed in such vague terms as to prevent operators from discharging mine water into the streams, thus putting the coal industry almost entirely out of business without the legislators realizing what they were doing.

E. A. Holbrook said that the acid in the streams had a most beneficial effect in that it destroyed the germs in the sewage dumped therein, and it was a pity that no careful inquiry had been made into this factor in "pollution." Looked at from that point it was difficult to determine whether the water from the mines polluted the streams or purified those that were already polluted. Mr. Taylor stated that by reason of the acid water from the mines and other sources it was not necessary to treat the sewage discharged by manufacturing towns.

In the evening some motion pictures illustrating the manufacture of charcoal and charcoal pig, the formation and eruption of volcanoes and matters of zoological interest were exhibited. A dance followed.

Rope Safety Received Renewed Consideration

The joint session of the industrial relations committee and the mining section of the National Safety Council met on Wednesday morning with B. F. Tillson in the chair. Rudolph Kudlich read a comprehensive paper entitled "Safe Practices in Mine-Hoisting Equipment." Commenting on this paper Mr. Sunderland said he agreed with the author that "the angle of fleet [the angle between lines drawn from the sheave to the center and the ends of the drum] should be kept within 1½ deg." He would add, however, that where the drum had an ungrooved face the fleet should be less. He recommended watching the interior wires when cutting a rope. The internal was more important than the external wear, as exhibited by breaks in the surface wires.

B. F. Tillson urged that where tracks were good, even 3,000 ft. a minute was not excessive in hoisting men. He did not believe the greater speed with good tracks was any more dangerous than 500 ft. per minute. In case of an accident the probability of fatalities would be equally menacing. Mr. Stone asked if the factor of safety suggested was based on the load or on both load and bending stresses and was told that it was based solely on the former. B. F. Tillson said that unfortunately the factor of safety had to be kept at a lower figure in deep shafts than in shallower ones, for in a deep shaft the rope was so long that it was impossible

to get a high factor of safety, the rope itself being the real burden to be supported.

Turning to fire protection, a paper written by Orr Woodburn, of Globe, Ariz., was read. C. A. Mitke of Bisbee, Ariz., delivered a similar address. He said that at Globe the question arose as to whether a reversible fan should be installed. It was decided that the temptation to reverse a fan sometimes was so strong in case of a mine fire that men would yield to it, with disastrous results, and that it was better therefore to have the fan non-reversible.

Knowing that the fan could not be reversed, the men would know what they should do and would not be uncertain as to the way in which the air would travel. However, the men at Globe, who had been reading about the Argonaut disaster, were of a different mind. They wanted arrangements made so that they themselves could reverse the fan. Orders and notices sometimes avail nothing in preventing reversal where a fan can be reversed.

A Reversal That Almost Caused Fatalities

At the Jerome (Ariz.) mines the manager went down to fight a fire and left strict orders that the fan was not to be reversed. The man in charge of the fan obeyed orders despite all persuasion till after about two hours when the manager had not returned. Flame beginning to show up and the manager having failed to leave the shaft at the time he had set for his return the man reversed fan, and the manager barely escaped death from the noxious gases thus driven toward him.

Mr. Mitke said that only after much discussion with Mr. Woodburn did the men consent to give up their notion. The reversal of a fan takes about 15 minutes and the air is not immediately reversed thereby, consequently with every reversal there is a period of uncertain movement, and the results sought may not be attained. Furthermore the fan may be reversed, but the doors, not being secured, will be opened by the reversal. Mr. Mitke urged control of doors electrically. The cost of supplying reversal equipment of fans was not expensive. No one, certainly not the Old Dominion Co., would begrudge the cost, but unfortunately the power to reverse was so likely to be misused that it was better that it should not be provided.

George S. Rice read the new provisions to be required hereafter at California mines and said that at the Cherry mine disaster the evidence all showed that reversal was advisable. Where the air entered by an unconcreted shaft the gases from a fire in that intake might be spread all over the mine by means of the fan. Many extremely deep shafts could be concreted only at a prohibitive cost. To require that they be concreted would involve the closing of the mine. Guniting is not so expensive and would be effectual in preventing a fire if the gunite was unbroken. Where the shaft was in moving ground, however, gunite was not effectual, and many shafts were subject to such movement.

Another speaker said that, after all, reversal might take place as a result of the fire, whether that reversal was desired or not, and, moreover, the slowness with which a fan can be reversed might be corrected by operating the doors by electrical means. B. F. Tillson read a paper on fighting mine fires by hose, declaring that he believed it would be better to use a small hose and small nozzle and use water under high pressure rather than use a larger hose and limit the pressure. He had put a plate with a circular hole in it in the outlet of his globe valve so as to limit the outflow of water. George W. Booth, of the National Board of Underwriters, agreed with Mr. Tillson, saying that in houses the fire departments were using 1½-in. hose with ¾ in. nozzles with a fixed orifice such as Mr. Tillson was advocating.

Mr. Tillson also commented on the variety of hose connections and Mr. Rice called attention to the fact that at the Cherry mine disaster it was found that the Chicago fire department was helpless because it could not connect its hose to the water lines of the coal company. Mr. Rice said that the recommendations as to the size of hose and the pressure in the line in Technical Paper No. 43 were based on experiments made with the aid of the National Board of Underwriters after the Cherry mine fire. He was not unwilling to admit that further inquiry might reveal that high pressures and small diameters were desirable. All the recommendations for legislation made by the committee formed after the Cherry mine fire had been found practicable and of value except that for automatic fire alarms.

Mr. Booth said that more and more the fire departments of the cities were coming to the 7½ taper thread prescribed by the standard. He added that this standard was made twenty years ago. It seemed likely, he said, that if a new standard were made today it would be of 6 threads to the inch instead of 7½. Those who had coupled on a hose in a volunteer contest would recall how easy it was to get the threads crossed. With the iron pipe thread the difficulty, of course, was much greater.

Formed Committees and Talked Over Problems

J. N. Houser, general manager of the Tennessee Copper Co., at Copperhill, Tenn., described that company's methods of selecting committees and talking matters over with its men and inducing them to accept readjustments. Clarence Starr asked several questions as to the reaction of the union to such an arrangement and to readjustment of wages, discovering much difference between the anthracite region, where men are scarce and unions are entrenched, and the copper situation, where in the recent hard times men were in excess and the union weak. Dr. Jau Don Ball's paper on "Industrial Psychiatry" was briefed by T. T. Read. Apparently "psychiatry" is the science of dealing with the subnormal man—the man with the ingrowing grouch and the "inferiority" complex. "Psychology" is the study of the mind of the normal individual, "psychiatry" that of the diseased mind of the subnormal man. The author thought that industrial relations should be in the charge of experienced psychiatrists as the subnormal mind is all too prevalent.

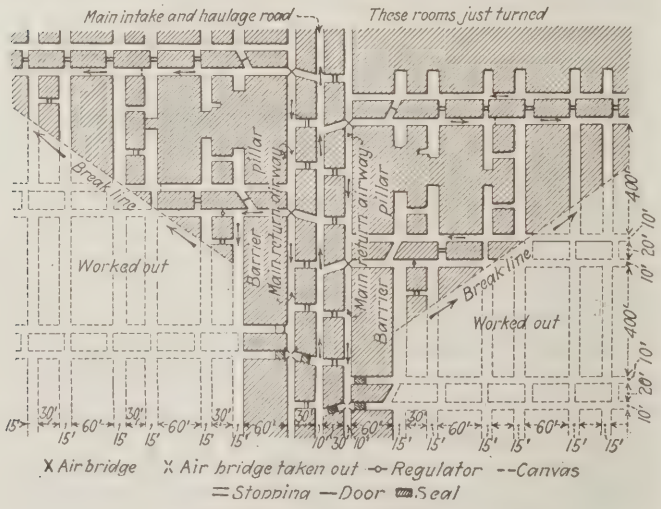
The banquet of the evening of Wednesday was marked by the modest but intensely interesting description by Prince Gelasio Caetani, Italian Ambassador, of his training at Columbia, his experience as a cub engineer in the Far West and Alaska and his exploit during the war in blowing off the top of the Col di Lana, the eye of the Austrians, which towered 10,000 ft. above the sea. The first Douglas medal was presented to Frederick Laist, manager of the Anaconda Copper Mining Co., for his advances in the art of metallurgy.

On Thursday, Feb. 22, a visit was made to the plant of the American Brass Co., at Ansonia, Conn., where the visitors were entertained by the company and conducted in three large parties through the works.

Problems of Operating Men

Edited by James T. Beard

Standardizing Methods in the Mining of Coal



Driving Main Entries Three or Four Abreast —Narrow Stalls Driven in Pairs Off the Butts—Other Precautions to Avert Disaster

EVERY mine should be planned with the constant aim in view of securing the largest percentage of extraction of the coal while insuring the greatest degree of safety to the workers. It is generally recognized that the chief sources of danger, in coal mining, are the fall of rock and coal at the working faces and the presence of gas and dust in the mine air.

These items should be kept in mind continually when considering the method of working best adapted to the conditions in hand. We all know that different methods of working are adapted to different conditions regarding the character of the roof, floor and coal, depth of cover, thickness and inclination of the seam and other items.

Speaking generally, however, and assuming the room-and-pillar method (bord-and-pillar), or the pillar-and-stall method, is to be employed in preference to longwall, there are features that lend themselves to safety, in the planning of the work.

With this explanation, allow me to present the plan shown in the accompanying figure, which appeals to me

PROPOSED STANDARD PLAN FOR ROOM-AND-PILLAR WORK

as the standard of working coal in this and many other districts. No doubt the plan can be modified.

The plan shows the main headings driven three abreast, in which case the center heading is made the main haulage road and intake for the entire mine, and the two flank headings will then serve as the return air-courses for their respective sides of the mine. In my judgment, there should not be less than three main headings as here shown.

In the working of a large gassy mine, it will often be found an advantage to drive the main headings four abreast. However, I consider that the limit, as a larger number of headings is apt to prove a menace to the safety of the mine, by reason of the headings becoming dry and dusty.

When the main headings are driven four abreast, the two center headings are intake airways, one being used for the haulage road and the other as a manway. This arrangement, I believe, is particularly advantageous in the working of a gassy seam.

Gassy Mine Requires Duplicate Exhaust Fans to Insure Uninterrupted Circulation

As shown in the figure, the mine should be equipped with two exhaust fans of equal dimensions, one fan working on each main return heading. Butt headings are driven in pairs to the right and left of the main headings, on 450-ft. centers, leaving a solid block of coal 400 ft. wide between each pair of butts.

One main feature, in respect to the safety of working, is the driving of narrow rooms or stalls in pairs. In the figure, these are shown as driven at right angles to the butt headings. The stalls are 15 ft. wide and separated by a 30-ft. pillar. As shown in the figure, a solid pillar of coal, 60 ft. in width, is left between each pair of stalls. This plan provides for a one-fourth extraction in the first working, the remaining three-fourths being left to be taken out when retreating.

The driving of narrow stalls, with wide pillars between them, is not only a safeguard against falling roof and coal; but it will, in most cases, reduce the cost of production by requiring less timber and avoiding loss of coal in drawing back the pillars.

Arranging a Uniform Breakline

All haulage roads should provide a good clearance on both sides of the track. As shown in the figure, overcasts are built at the mouth of each pair of butt entries. These are taken down and the air-course to that pair of headings sealed when the breakline has reached the face of those headings. At the same time, a canvas is hung, or a regulator installed at the mouth of the entry, to prevent the short-circuiting of the air when the overcast is removed.

As a further precaution in avoiding disaster, a water line, under 80 lb. pressure, should be laid in all entries. Also, during the winter months, steam should be introduced into the intake air, for at least four hours each day when the men are out of the mine.

Too rapid a development of the mine is always a source of danger and should proceed only fast enough to keep ahead of the breakline. At the working face, all coal should be blasted down before the miner is permitted to start loading. If this is done, it will go a long way toward reducing the number of accidents from falls of coal in miners' places.

Parnassus, Pa. C. W. Atkins.

Competent Machine Runners

Factors that increase cost of machine work—Need of efficient plan—Employing too small a number of machines gives poor results.

I HAVE read with much interest the timely article by O. Kennett in the issue of *Coal Age*, Jan. 4, p. 18. He has opened a subject worthy of general discussion. I believe there is no one class of mine work that gives more trouble and is the cause of greater expense than the operation of chain machines. All that Mr. Kennett has stated is true and I hope to add some further thoughts to keep the subject alive.

Having operated machines under various conditions I have about reached the conclusion that the high cost of machine repairs, the big bottoms left in every other place and the increasing number of accidents from this kind of work is entirely the fault of the plan of operation and not so much due to an indifferent class of workmen.

Pell-Mell Drive Increases Cost of Cutting

To illustrate this point, let us assume a mine where the coal is cut by the ton and the cutting is done at night, on account of insufficient power to do it on the dayshift. Usually, under these conditions, as few machines as possible are used, in order to conserve the power, and the result is that each cutter has, say twice as many places to cut as he should have. The result is a pell-mell drive, a stop-for-nothing attitude to cut the places assigned by the boss.

The cutter starts "sumping up." He strikes something hard and away goes a few of his bottom bits. He does not take the time to pull out the machine and replace the broken bits, with new ones. Instead, he keeps a going and when he gets to the opposite side of the room he is about a foot off the bottom. The fact that he has left big bottoms in a room means nothing to him and he cares little about his overworked machine. His only thought is that his wages do not take a slump and he manages to hold the machine together until the shift is over.

While it requires a sturdy machine to stand this grind, it takes a still stronger man to stay with the machine and the fact that he is making good wages makes it a matter of little importance to him when he is blamed for carelessness and indifference. The man, indeed is about exhausted when the shift is over and, as a result, sickness may keep him from work for a day or two. He is even ready to quit if pressed too hard for an explanation of the condition of his machine.

Cutting Arrangements Must Be Favorable to Execution of the Work

It is not profitable to subject machines and men to this kind of treatment. All operators should so arrange their system of cutting that a machine crew will have a fair chance and be able to do their work right and safely. The best way to bring this about is to put cutters on during the day. This may, of course, necessitate buying more machinery, but it will pay in fewer repairs being required and providing more satisfactory working conditions.

No man wants big wages if he must kill himself to get them. Moreover, the knowledge that cutters and scrapers are making such big wages does more to dissatisfy other workers than anything else. The only men who know how much hard bone labor is involved in cutting eighteen places with a shortwall machine are the men who go in, night after night, and do it under the trying conditions found in the average coal mine.

Finally, in regard to the suggestion that the electrician should employ the machine men, I do not agree with that idea. To my mind, the mine boss should bear that responsibility entirely alone. The electrician is one of the most important men around an electrically equipped mine. He has his hands full when he keeps the machinery going, without being bothered about keeping the machinery manned.

One plan I have seen that brought good results was where the cutter was permitted to select his scraper. Another instance was where the electrician or an assistant examined all machinery once a day, even to the farthest mine pump or rock drill.

Pikeville, Ky. George Edwards.

Care Needed in the Operation of Coal-Cutting Machines

Careless handling of machine invites trouble—Machine must be oiled regularly—Correct use of controller averts burning of contact points—Cutting for speed dangerous.

THE excellent article on the employment of competent machine runners, which appeared in *Coal Age*, Jan. 4, p. 18, has expressed a new opinion and one that should prove of vast interest to operators of machine mines.

The writer of the article emphasizes the fact that an inexperienced or careless operator can do serious damage to a machine in a short time. He may cause injury to himself or his helper, to say nothing of the loss of time and expense suffered by his employer as the result of his neglect or lack of knowledge.

It is important to remember that carelessness in the operation of a machine, particularly a coal cutter, acts as a magnet to disaster. In the handling of men and machines, for several years past, it has been my chief objective to discover and avoid habitual carelessness in workmen.

Numerous Types of Machine Runners Who Damage Machines in Various Ways

Among machinemen, a dangerous type is the speeder, who cuts coal with the sole thought in mind of increasing his wages. He neglects to oil his machine and, by this and other lack of care, damages the machine, endangers his own life and that of his helper and then produces a lesser tonnage than the man who works with greater moderation and more steadily.

One matter of chief importance in running a coal-cutter is to understand the proper use of lubricant. The machine must be kept well oiled. This is much neglected by the average runner, who fails to realize its importance to the work performed. The failure to use a proper amount of oil, by a machineman, should be promptly investigated by the company as it means a saving of expense and an increase in production.

Great damage will result from continuing to run a machine that has not been properly oiled. In many cases, the result is hot bearings that have to be rebushed at a great loss of time and expense. On several occasions, I have known the machine boss, on being called to repair a machine, would find the bearings badly scored by reason of being run without oil or other lubricant.

Coal-cutters must operate, necessarily under hard conditions, which require greater carefulness on the part of the runner to avoid damage to the machine. A careless operator will allow the oil openings to become clogged with fine dust and dirt and seldom make any effort to clean them out sufficiently to permit the oil to reach the bearings.

At times, the fiber washer on the bottom of the main gear becomes soaked with oil carelessly poured over the machine. The result is the runner tightens the friction nut to cause the machine to haul. This gives an effective pull on the feed-chain when the oil has worn away, greater than that for which the chain was designed and the latter is broken. Replacing the broken link means a loss of time, but the mended chain is seldom a satisfactory part of the equipment.

Need of Testing Each Machine Regularly

With every machine there is always sent a device for testing the pull of which it is capable. The machine should be tested at least twice a month, in order to keep the friction properly regulated. Too often this device is thrown aside and forgotten; or it may have been tossed out on the junk heap.

Another type of machine runner is a controller fiend, so to speak. Such would I describe the fellow who has little concern in his use of the controller when starting his machine. He will throw the handle from the first position around to full input, hardly allowing any time for the motor to pick up speed. The result is the burning of contact points, which makes it a dangerous practice.

Assume, for a moment, that this occurs when the machine is cutting up to the rib, the result would possibly break the feed-chain or pull the jack-pipe from the hitch supporting it. The jack falling might harm the machine; or, perhaps, break the cutter chain if the machine was not making a full cut. It would be fortunate if it did not cause the binding of the machine under the cut.

When the Machine Binds in the Cut the Runner Must Act Promptly

In that event, the friction should be promptly released and the bit clutch disengaged; or the emergency plug at the rear of the machine should be pulled. Never try to operate a machine when the contact points are burned on the starting box. It is better to stand the loss due to the machine being out of commission than to run the chance of accident.

I have mentioned the speeder—the man who is cutting for high wages. This fellow is careless of his own safety when working around a machine. He will take his life in his hand by stepping across the cutter-bar when the machine is running. If the machine should, at that moment, strike a hard substance and kick, or if the man's trousers should catch in the chain bits the poor fellow would be torn to pieces, before the machine could be stopped.

In closing, let me urge more care in selecting men who are habitually careful in running their machines. We should remember that the efforts of a few, in this direction, may prove the safety valve of the multitude.

The efficient machine man is one who cares more for his machine than for the amount of coal he cuts. He will always be on the watch to detect anything that is wrong and will keep his machine well oiled.

Armbrust, Pa. W. D. Rhodes.

Inquiries Of General Interest

Best System of Rail Bonding in Mine Haulage

Welding Fishplates to Rails and Cross-bonding by Welding Steel Ties to Rails Every 100 Ft., as Compared with Flexible Bonds Made for Bonding

IN OUR mine, which is electrically equipped, it has been the custom to weld the fishplates at all rail joints, so as to give a good electrical contact, besides welding the rails to the steel track ties every 100 ft. This was done, perhaps, through preference, or, it may be, to save the cost of buying flexible rail bonds made expressly for the purpose.

It is my desire, now, to learn what *Coal Age* and others think of this method, in respect to its relative efficiency and cost, as compared with other means of securing the same results. It seems to me that the matter of rail bonding, in reference to mine haulage, is worthy of discussion. The question is, Are we getting the greatest possible efficiency, per dollar expended?

We shall watch for the reply to this question and the later accounts of the experiences of others with deepest interest, as I am assured we can all profit by such a discussion. Mine Manager.

La Salle, Ill.

This correspondent has probably voiced the thought and wish of numerous other operators and mine officials who have been blindly following some previous practice or method installed by a predecessor, years before, and has not had the courage or ingenuity to question its relative efficiency and devise ways of improving the situation. In other words, there are too many mine officials who are satisfied to let well enough alone and plod along in another's tracks. They are not progressive.

The question presented is one capable of much profitable discussion, as coming issues of *Coal Age* will undoubtedly show. In the opinion of the editor, there is no system or method of bonding the rails of mine tracks that can compare, in respect to all-round efficiency, with the use of flexible rail bonds that are manufactured for the purpose and now so widely used in mining practice, in every district, both in this country and in Great Britain. The extra first cost of the equipment will soon pay for itself in lesser cost of upkeep.

Different types of these bonds are illustrated and described together with much other information regarding bonding in Catalog No. 18, recently published by the Ohio Brass Co., Mansfield, Ohio. When a good type of flexible bond is properly applied there is little need, generally, for the cross-bonding mentioned by the correspondent and this extra work of welding the rails to the track ties becomes unnecessary.

The question is open for the discussion of its merits by those whose experience in rail bonding will be of value to the industry and we hope there will be a generous response to this appeal.

Examination Questions Answered

Miscellaneous Examination Questions

(Answered by Request)

QUESTION—*The quantity of air passing in a mine is* 200,000 *cu.ft. per min. The average temperature of the return air is* 60 *deg. F. all the year round. On a certain day in winter the temperature of the intake air is* 20 *deg. F.; and on a certain day in summer it was* 65 *deg. F. Then, assuming that, in each case, a cubic foot of air at the inlet weighs* 0.08 *lb. when estimated at a temperature of* 32 *deg. F., what is the difference in horsepower required to produce the given circulation in these two periods?*

ANSWER—A cubic foot of intake air, at the winter period, is then (460 + 32/460 + 20) 0.08 = 0.082 lb.; and at the summer period, (460 + 32/460 + 65) 0.08 = 0.075 lb. The difference in the weight of the intake air in winter and summer is, therefore, 0.082 — 0.075 = 0.007 lb. per cu.ft. But the temperature of the return air being constant throughout the year, the weight of the upcast column is constant and the weight of the downcast column, in winter will exceed that in summer by 200 × 0.007 = 1.4 lb., which is the excess in ventilating pressure due to change of season, expressd in pounds per square foot.

Expressed in horsepower, it is fair to say, the circulation of 200,000 cu.ft. per min., in this mine, will require (200,000 × 1.4) ÷ 33,000 = 8.48 hp. less at the winter than at the summer period.

QUESTION—*Name three essential elements in the efficient ventilation of a mine.*

ANSWER—(1) A sufficient volume of air must enter the mine to comply with the requirements of the law and to make the mine safe for work. (2) The air must be divided and conducted to and made to sweep the working faces, in each district or section of the mine, so as to keep each place clear of gas. (3) The quality of the air with respect to oxygen content, humidity and freedom from gas and dust, must be such as to make it healthful to breathe and safe.

QUESTION—*(a) What will be the rubbing surface in an airway* 3,000 *yd. long,* 6 *ft. high and* 12 *ft. wide? (b) How much air will pass in this airway if the velocity is* 565 *ft. per min.?*

ANSWER—(a) The perimeter of a 6x12-ft. airway is 2 (6 + 12) = 36 ft. For a length of 3,000 yd., the rubbing surface is 3 × 3,000 × 36 = 324,000 sq.ft.

QUESTION—*Why is it necessary to place a regulator in a given section of a mine?*

ANSWER—A regulator is required in any section of a mine that takes more than its due proportion of the circulation because of its lesser resistance. The regulator restricts the flow of air in that section by offering additional resistance.

QUESTION—*How should a hoisting cable be attached to the cage?*

ANSWER—A steel rope socket such as is commonly used in hoisting practice, or a steel thimble must first be attached to the end of the rope. To attach the socket the end of the rope is first passed through it from the small end of the bore. The strands are then parted and some of the wires cut out of each strand. The remaining wires are bent back on themselves and the rope now pulled back into the socket. The bore being conical, the enlarged end of the rope formed by bending back the wires holds it fast in the socket. A steel wedge is driven down into the center or lead is used to fill the socket and bind the wires.

When the thimble is used as a rope end attachment the rope is simply wound around the thimble and the end secured by clevices binding it to itself, or the end is spliced into the main body of the rope.

QUESTION—*Why are spring safety catches to be preferred to those operated by weight and lever?*

ANSWER—The spring acts independently and is more reliable than the weight and lever, the action of which depends on gravity. When the cage is falling the weight falls with it and, as a consequence, exerts no force to move the lever that controls the catches.

QUESTION—*What quantity of air is required to ventilate a mine (Ill.) in which are employed* 150 *miners,* 21 *daymen,* 10 *mules being used to haul the coal?*

ANSWER—The Illinois Mine Law (Sec. 14) requires the circulation of 100 cu.ft. of air, per man, and 500 cu.ft. per mule, where the mine is not gaseous; or 150 cu.ft. per man if gaseous. Assuming the former condition, the air required, in this case, is 100 (150 + 21) + 500 × 10 = 22,100 cu.ft. per min.

QUESTION—*If* 60,000 *cu.ft. of air per minute is produced under a water gage of* 1.6 *in. what is the horsepower of the ventilating current?*

ANSWER—A water gage of 1.6 in. corresponds to a unit pressure of 5.2 × 1.6 = 8.32 lb. per sq.ft. The horsepower on the air is then (60,000 × 8.32) ÷ 33,000 = 15+ hp.

QUESTION—*An airway has an area of* 66 *sq.ft. and the reading of the anemometer is* 675 *ft. per min. What is the quantity of air passing, allowing* 4 *per cent for the resistance of the instrument?*

ANSWER—The velocity of the air current, making this allowance for the resistance of the instrument, is 675 (1 — 0.04- = 648 ft. per min. Then, taking this as an average velocity of the air current, the volume of air passing is 648 × 66 = 42,768 cu.ft. per min.

QUESTION—*Suppose you were testing for fire damp and an explosion occurred in your lamp, what would you do?*

ANSWER—If the explosion did not force the flame through the mesh of the gauze it is fortunate. Keep cool and lower the lamp promptly but cautiously, screening it as much as possible from the air while withdrawing from the place. Any quick movement of the lamp would always be dangerous.

QUESTION—*Should a fall occur on the intake airway and a large amount of marsh gas be given off from the roof, what steps would you take to prevent an explosion and rescue the men at work inside?*

ANSWER—Notify the men at once to extinguish their lamps and withdraw by the safest possible route. When the men have passed out of the mine station reliable men at the entrance to prevent anyone from returning. The work of conducting the gas by the shortest route out of the mine should then be undertaken by the firebosses. Before the men are allowed to again enter the mine, every portion must be carefully examined and the mine reported safe for work.

Raise Pay of Independent Alabama Miners

Birmingham, Ala., March 1.—Wage increases averaging 12½ to 15 per cent for mine workers in the pits of the Tennessee Coal, Iron & Railroad Co. were announced by the company today. The increase, effective March 15, affects approximately 10,000 coal and ore diggers of the Tennessee company, and brings the new wage close to 50 per cent higher than the level of May, 1922.

The first increase, effective May 15 last, was 10 per cent; the second, effective Sept. 1, 20 per cent.

Independent operators have announced their intention of making substantial increases, effective March 15. The scales now being worked out are expected to follow the lead of the Tennessee company.

The Alabama division of the United Mine Workers is now working out a scale of wages which will be demanded in union mines, it is announced. The Tennessee company operates on an open-shop basis.

Midwest Roads Offer "Compromise" on Mine Ratings; Operators Object

The railroads of Illinois, Indiana and western Kentucky late last week came back with what they say is a compromise proposal for a new system of rating coal mines for car supply. They propose that they create a joint railroad board of three men to rate all mines in those three general territories on the mines' past performances, using only full-day operation as a basis. If any mine is aggrieved it will be permitted to have its claimed rating until such time as the board gets around to re-examine it, in case that re-examination is not made within ten days. This plan meets the hearty disapproval of most Illinois and Indiana operators. Several of them said they would not agree to it but would take the matter back to the Interstate Commerce Commission, which still has the car-rating case under consideration.

What the operators of Illinois and Indiana insisted upon at a conference with the railroads in Chicago two weeks ago was that each mine be rated each month on the performance of the preceding month as under CS 31, now in effect. Western Kentucky was agreeable to the carriers' plan provided it were not applied to that field alone. Many of them believed tipple hours and not underground working time should be the basis. They offered as a "compromise" that the roads create their proposed rating board but that the monthly basis be preserved. This the roads have now declined to accept.

The new proposal of the roads varies little from the original and does not introduce the element of flexibility in rating for which the operators have been contending all along. Car ratings should change from month to month with the change in coal demand and with the consequent fluctuations of production is the opinion of most well-informed coal men.

190 Died in January Coal-Mine Accidents; 3.23 per Million Tons Mined

Accidents at coal mines in January, 1923, according to reports from state mine inspectors to the U. S. Bureau of Mines, resulted in 190 deaths. Based upon an estimated production of 58,891,000 tons, the fatality rate was 3.23 per million tons mined, as against 3.65 in January last year, a reduction of more than 11 per cent. The average fatality rate for January over a ten-year period (1913-1922) is 3.96 per million tons; thus the rate for January, 1923, represents a decrease of nearly 19 per cent from the 10-year average rate for the month.

The explosion of gas at Dolomite mine No. 1, at Dolomite, Ala., on Jan. 10, which resulted in the death of five men, was the only major disaster reported for the month. In January last year there also was but one major accident, a dust explosion in a coal mine in Kentucky, in which six lives were lost.

The reports for January, 1923, show slight decreases in the fatality rates per million tons from falls of roof and coal, mine haulage, gas and dust explosions, and powder and other explosions, as compared with the accident record for January, 1922.

COAL-MINE FATALITIES DURING JANUARY, 1923, BY CAUSES AND STATES

(Compiled by Bureau of Mines and Published by *Coal Age*)

State	Underground													Shaft					Surface							Total by States	
	Falls of roof (coal, rock, etc.).	Falls of face or pillar coal.	Mine cars and locomotives.	Gas explosions and burning gas.	Coal-dust explosions (including gas and dust combined).	Explosives.	Suffocation from mine gases.	Electricity.	Animals.	Mining machines.	Mine fires (burned, suffocated, etc.).	Other causes.	Total.	Falling down shafts or slopes.	Objects falling down shafts or slopes.	Cage, skip, or bucket.	Other causes.	Total.	Mine cars and mine locomotives.	Electricity.	Machinery.	Boiler explosions or bursting steam pipes.	Railway cars and locomotives.	Other causes. U. S. Coal Commission Granted $400,000 Appropriation; Union Not to Have Access to Cost Reports

By Paul Wooton
Washington Correspondent of *Coal Age*

While the continuance of the President's Coal Commission was imperiled by the delay in voting its appropriation, Congress in an eleventh-hour effort gave the commission all of the legislation which it had asked. This included the appropriation of $400,000, the authorization to require sworn answers to questionnaires, the extension of the life of the commission until Dec. 31 and the authorization for Judge Alschuler to serve as a member of the commission.

The appropriation was added to the third deficiency bill in the Senate. It was approved with practically no objection. A separate vote on the amendment was demanded in the House, but the item was approved without a roll call. Prior to that action, however, the House had passed the bill which authorizes the commission to require sworn answers to its questionnaires. The amendments to the original act included the desired increase in the appropriation. The amendments were approved by a vote of 212 to 76.

When the deficiency bill was taken up in the House Representative Blanton, of Texas, opposed the coal commission appropriation and also further investigation into the coal industry.

Representative Goodykoontz, of West Virginia, seconded the effort made by Mr. Blanton to force Chairman Madden of the House Appropriations Committee and in charge of the bill, to give assurances that the commission appropriation would be striken from the bill. Chairman Madden, however, refused to give such assurances.

Chairman Hammond of the coal commission, when called upon by the chairman of the Committee on Appropriations of the House of Representatives to justify the $400,000 additional which the commission was asking, said in part: "We can justify this appropriation simply from the recommendations of a practical nature that we can make regarding improvement in mining methods, in the relations between the operators and employees and in many other respects. I am confident that the engineering recommendations alone will justify this appropriation many times over each year. The industry is the worst conducted, from an engineering point of view, that I have ever seen."

The commission had asked originally for authorization to extend its activities to Dec. 31, if that should be found necessary. Since that time the situation which prompted that request has changed sufficiently to make it practically certain that the commission can conclude its work by Sept. 22, the original date set. Congress, however, did not take cognizance of the fact that the commission no longer believes that an extension if its term is necessary and authorized the President to advance the limit as might be found necessary to a date not later than Dec. 31. In commenting on that phase of the legislation, Chairman Hammond stated that he can foresee no contingency that will interfere with the submission of the final report on Sept. 22.

In the same manner Congress took no note of the fact that Judge Alschuler had tendered his resignation to the President and that the President had accepted it. The action of Congress in authorizing him to serve on the commission was entirely unexpected.

The attention of the commission has been called to the plan, encouraging coal storage by the small consumer, which was devised by L. S. Storrs, president of the Connecticut Company, large operators of electric railways. Mr. Hammond and Commissioner Smith are outspoken in their commendation of the plan whereby the company guarantees payment for the orders of domestic fuel placed by their employees on April 1. The plan is to be called to the attention of large employers in the belief that it offers the opportunity to obtain the maximum possible amount of storage on the part of domestic consumers.

While it would be outside the province of the coal commission to request state legislatures to postpone consideration of pending coal legislation until the commission reports, Mr. Hammond did point out on Saturday that it is obvious that the state as well as the federal government would be in a position to legislate much more intelligently if it had before it the basic facts which the commission is assembling. This statement was called forth by a letter on the subject addressed to the commission by the bituminous operators' special committee.

In connection with the announcement that W. Jett Lauck is to serve the commission on certain special assignments it was pointed out that Mr. Lauck does not have access to the commission's files. Mr. Lauck has been so actively connected with union activities that his appointment is not being met with favor in all quarters. Evidently with the idea of anticipating some of the opposition, Mr. Hammond pointed out that Mr. Lauck is not to be regarded as a member of the regular staff but that he feels advantage should be taken of the service that Mr. Lauck can render in certain matters in which he has had special experience. In connection with that discussion attention was called to the fact that the information contained on questionnaires is scrupulously guarded by the commission. With the exception of the men specially chosen for their reliability, who compile the data from these returns, no member of the commission's staff has access to these questionnaires.

Miners' Representatives Not to See Cost Figures

In one of the communications submitted to the commission recently by the United Mine Workers it is asserted that the commission has promised to allow the examination of cost figures by miners' representatives. Mr. Hammond is at a loss to know how any such misunderstanding should have come about. That the officials of the United Mine Workers had this misconception first came to the attention of the commission in January. At that time the presidents of the anthracite districts were distinctly informed that the promise is confined to the matter of miners' earnings. The commission expects to allow the unions to check payroll figures as reported by mines in the union fields. Both Mr. Hammond and Dr. Smith subscribe to the following: "This commission as it is organized is as well qualified to analyze and criticize figures and accounting systems as is either party to the controversy between the operators and miners. Indeed we represent both of them, as well as the consumer. When it comes to the examination of the records in this investigation, everyone concerned must put some confidence in the integrity and efficiency of the commission. We know we are impartial and we intend to be thorough."

Chairman Hammond, Governor Marshall and Mr. Howell are spending this week in Alabama. They decline to prepare an itinerary and will look around as it suits their own fancy, with the idea of building up first-hand information and a general background which they believe necessary to the intelligent determination of many questions. Dr. Devine is visiting mines in Oklahoma and Texas.

Regardless of what the unions may think, Mr. Hammond is convinced that coal mines should operate at least sixteen hours a day. He says it is so obviously poor business to obtain but one-shift production from a mine, which represents large capital expenditure, that he feels more general resort to a two-shift system should be undertaken. He said some investigation already has been made as to the possibilities of obtaining substitute employment for the 200,000 or more men which would not be needed in the coal mines if the industry were conducted in the most efficient manner.

It was revealed at Saturday's conference with representatives of the press that the commission is receiving many requests from New England for additional supplies of anthracite. Dr. Smith expressed regret that the commission has been unable to disabuse the mind of the domestic con-

sumer in New England of the impression that the commission has power over distribution. He said it is to be regretted that Federal Fuel Distributor Wadleigh does not have the miraculous power of furnishing the 40 per cent of the anthracite production lost during the strike.

Chicago, March 6.—Judge Samuel Alschuler married Miss Ella Kahn, daughter of a wealthy clothing manufacturer, in Chicago March 5. Judge Alschuler, who is 63 years old, had been a bachelor.

Sufficient Anthracite Moving to Satisfy Real Needs of Northeast, Says I. C. C.

The Interstate Commerce Commission made a report Feb. 28 to the U. S. Senate in response to Senate Resolution 418, which directed the commission to investigate the advisability of ordering an embargo on anthracite coal to foreign counteries.

The substance of the commission's report is that after an exhaustive investigation and through co-operation of federal, state and local fuel administrators and of railroad officials, the movement of anthracite coal is sufficient at this time to take care of the real needs of the consumers in the northeastern portion of the United States, and that preference and priority is being given without materially changing the plans of operations that might arise from the imposition of a priority order upon the carriers, which are at present under great stress in operating their lines. The report further states that no substantial evidence as to purchase or sale of anthracite either unreasonable or unjustly high has been brought to the commission's attention.

Cushing to Speak Unofficially in Canada

George H. Cushing has accepted an invitation from the Canadian Mining Institute to present certain phases of the commercial situation of coal in Montreal this week. A request for such a presentation was received recently by the Secretary of the Interior from the Canadian Government. In reply Secretary Fall pointed out that his department is not in a position to speak for the commercial interests but suggested that Mr. Cushing had long contact with the marketing phases of coal. This resulted in the invitation being extended to Mr. Cushing by the Canadian Institute. While Mr. Cushing will appear as a private citizen and in no way will be authorized to reflect the views of government officials, because of the official correspondence that has been exchanged he submitted his speech to various officials conversant with coal so as to guard against any utterance that might embarrass them.

Drop Indictments in Clifton Mine Battle

Indictments charging 126 men with conspiracy to attack and destroy mine property at Cliftonville, W. Va., last summer were "nolled" in Circuit Court at Wellsburg, W. Va., March 5. The defendants had been at liberty under bond for several months. The charges grew out of the Clifton mine battle, in which Sheriff Duvall and six others were killed.

Lehigh Valley Dissolution Decree Filed

Attorney General Daugherty on March 3 ordered filed in the U. S. Court for the Southern District of New York a final decree for separation of the Lehigh Valley Railroad Co. from its coal subsidiaries. The representatives of the Attorney General were instructed to inform the court that the end desired by the government was the complete separation of the railroad company from the mining and selling of anthracite to such an extent that there should not be any connection, direct or indirect, between any stockholders or officers of the railroad company and of the coal companies.

On the same day Judge Learned Hand in New York heard a discussion on the separation plan proposed by the railroad company. Edgar H. Boles, general counsel for the railroad company, presented a full draft of the proposed decree. A. T. Seymour, acting U. S. Attorney General, said that while he considered the plan contained features intended to accomplish practical results he said he did not want to be placed in the position of agreeing to it, as the government wanted to bring about a complete separation between the railroad company and the mining and the sale of anthracite.

Judge Hand was told objections by stockholders of the railroad company had been presented to the Department of Justice.

McAuliffe Is Union Pacific's Coal Chief

Eugene McAuliffe, well known in the American coal industry, especially during his presidency of the Union Colliery Co. of Illinois since 1917, is now directing the coal affairs of the Union Pacific Railroad Co. On March 1 he became president of the Union Pacific Coal Co., operating sixteen mines in the Rock Springs (Wyo.) coal field, and president of the Washington Union Coal Co., operating the Tono mine at Tono, Wash. Mr. McAuliffe's offices are at the Union Pacific system headquarters in Omaha, Neb. E. S. Brooks who has been president of the railroad's coal company, continues as field chief in the capacity of general manager of the Rock Springs group of mines and is now a vice-president.

Mr. McAuliffe's step into the control of all Union Pacific coal properties and coal interests is but another stage in a striking career. Not so many years ago he was a "hogger" pulling a throttle on a freight engine. But he had ideas and never was satisfied with just holding a job. That was why he rapidly ascended from shop apprentice on the Northern Pacific in 1888 through various shop and engine-service jobs on various railroads in this country and Mexico until an official of the old Kansas City, Ft. Scott & Memphis, now a part of the Frisco system, pulled him out of the right hand side of an engine cab and made him fuel agent in 1903. In 1908 he became general fuel agent of the Chicago, Rock Island & Pacific, St. Louis & San Francisco, and Chicago & Eastern Illinois railroads and was elected president and general manager of the Brazil Block Coal Co., operating mines in Illinois and Indiana. He returned in 1913 to the St. Louis & San Francisco as general coal agent in charge of locomotive and shop-fuel purchases, coal-traffic and coal-mine development work. On Feb. 1, 1917, he resigned railroad service to joiin the staff of the North American Co., owners and operators of electric public utilities, coal-mining properties and river transportation facilities, serving as vice president of the West Kentucky Coal Co., later organizing the Union Colliery Co., where in the capacity of president and general manager he constructed and operated the Kathleen mine, in southern Illinois, assisting in the purchase of fuel for the public utilities in St. Louis, Milwaukee, Detroit and Cleveland. He resigned as president and general manager of the Union Colliery Co. in September, 1922, and has since engaged in special work for the North American Co.

EUGENE McAULIFFE

Explosion at Arista Mine in West Virginia Takes Toll of Ten Lives

An explosion at the Arista mine of the Weyanoke Coal & Coke Co. on the Widemouth branch of the Norfolk & Western Ry. in Mercer County, West Virginia, last Friday morning at 10:30 exacted a toll of ten lives and seriously damaged a part of the mine. The bodies of six of the ten miners killed were recovered on the day of the accident. It was impossible to reach the others until the following day owing to the destruction wrought by the explosion.

Other than it seems to have been a dust explosion, the direct cause is uncertain. Some of the officials of the company were inclined to believe that the dust might have become ignited by excessive shooting or because of a blown-out shot. First reports of the cause were to the effect that a runaway trip in striking the side of a passageway in the mine had raised dust which exploded. The force of the blast was such as to hurl timbers, boulders and other débris from the opening on the west side of the mine. The explosion was in the vicinity of the seventh, eighth and ninth entries of the west main, about 3,200 ft. from the entrance to the mine.

Until reorganized on Jan. 1, 1923, the Weyanoke Coal & Coke Co. was the S. J. Patterson Pocahontas Coal Co. It is owned by H. D. Patterson, a relative of the late John H. Patterson, of the National Cash Register Co.

R. L. Lambie, chief of the West Virginia Department of Mines, received word of the explosion within a few hours after it occurred and organized a party of mining inspectors and first-aid experts who left Charleston for Mercer County in the new mine-rescue car of the U. S. Bureau of Mines.

An explosion of three boxes of powder, Feb. 26, at the Superior mine of the Superior Fuel Co., near Curtisville, Pa., injured several persons, destroyed the powder house and two adjoining sheds, tore the roof off the main building, badly damaged the main machinery building and broke many windows in two small towns near by.

Coal Commission Engineers Gather Data In Central Pennsylvania Field

In conference with the board of directors of the Central Pennsylvania Coal Producers' Association last week in Altoona were M. B. Matson and Charles Young, mining engineers, working as personal representatives of John Hays Hammond, head of the U. S. Coal Commission. Later, engineers will visit the district and confer with the miners and with the officials of the United Mine Workers.

The engineers were studying the economic, labor and engineering phases of the industry and under these general headings are obtaining data on labor costs, production costs, investments, profits, wage rates, absenteeism, labor turnover, strikes and their causes, earnings, efficiency of union and non-union miners, living conditions, marketing, transportation, waste, overdevelopment, etc.

One of the primary objects of the visit of the commission engineers to the central Pennsylvania field was to stimulate operators and miners to take an interest in the investigation and furnish the commission with information that will prove valuable when it comes to reaching a conclusion. The engineers expressed themselves as well pleased with the hearty co-operation of the operators and the association in the central Pennsylvania field.

The Central Pennsylvania Coal Producers' Association, which embraces in its membership practically all the operators in the field, having withdrawn its affiliation with the National Coal Association, is now engaged in preparing the case of the district operators to be presented to the commission.

The association will give the commission the information desired as far as it is possible to do so. Data for form C-1, which covers cost, income and tonnage, and L-1, embracing earnings of miners, are being filled out as fast as the data can be tabulated. These forms are most elaborate and complicated and require much work.

Also a survey will be made by the operators covering investments and profits in the industry in the district from 1906 to 1921, inclusive, and the effects of competition and the decreasing tonnage in central Pennsylvania, which will be set forth in full in a brief that will be sent to the commission.

A discussion of the cause of overdevelopment of the industry in the district will be included and an attempt will be made to draw a proper distinction between development and capacity.

One of the chief features of the report will deal with the industrial situation between the operators and the United Mine Workers of District No. 2. The relations that have existed for twenty-five years and the changes that have taken place will be set forth and the full effects of the policies shown.

President Harding Makes Position Clear On New England Coal Situation

President Harding made clear his position on the New England coal situation in a letter to Representative Rogers written just before the adjournment of Congress. The letter follows:

"If I am quoted in the New England press as your letter indicated, it is the fault of the newspaper world in quotation, and the blame cannot be attached to me. I did say to the newspaper men, in a recent press conference, that representatives of the Interstate Commerce Commission had reported to me that their agents, who are sent to investigate every reported distressing situation, had said that much of the trouble was 'psychological' and that there was a good deal of hysteria because of the menacing depletion of fuel supplies on hand. I have recognized all along that there is a very anxious situation in New England. I do not see how such a situation could be avoided.

"All the country knows that we had a coal strike last summer of several months' duration and that, in spite of everything that the federal government could do, the strike very greatly diminished our normal supply of anthracite coal. As a matter of fact we are passing the winter on about a 60-per cent supply. In these circumstances I do not see how great inconvenience and much distress could be avoided. Communities accustomed to the use of anthracite coal have rebelled against any substitution of bituminous coal and have hoped from week to week and day to day to obtain an ample supply of anthracite. The ample supply is not available. From the time of the very first complaints coming from New England I have transmitted them to the Interstate Commerce Commission, which is the only governmental authority we have to deal with the situation. To be sure, the Federal Fuel Distributor is authorized by Congress to make recommendations, and these recommendations have been made with great earnestness.

"There is no one with power to tell the commission what to do. Priority orders have been recommended, but the commission is clearly reluctant to resort to that remedy. Members of the commission report to me that every reported distressing situation is being promptly investigated by personal representatives of the commission, and that necessary steps are very promptly taken to afford relief. I should be glad, of course, to see every apprehension removed. If someone will tell me wherein I have the authority to do so I will be glad to adopt vigorous measures. I do not think it is either prudent or desirable to attempt an embargo.

"It does not help the situation, but I venture to express the hope that the Congress will make provision to carry on the work of the Fact-Finding Coal Commission so that the very unfortunate state of affairs so often reported this winter will never be possible again in the United States."

MEETING ON LAKE TRAFFIC.—A meeting of the Lake Committee of the West Virginia Coal Association was held at the Washington Hotel, Washington, D. C., March 2 for the purpose of considering Lake traffic for the coming season. No action was taken at this meeting but it was arranged to hold a further meeting subject to the call of Mr. Hartwell of the Northwest Dock Operators' Association.

Prof. H. H. Stoek Falls Dead

Harry Harkness Stoek, professor of mining engineering in the University of Illinois, Urbana, Ill., and a former leader in coal mining circles in Pennsylvania, fell dead March 1 in an automobile painting shop in Champaign, Ill.

Professor Stoek had been professor of mining engineering and head of that department in the University of Illinois since 1908 and previous to that date had occupied a prominent place in Pennsylvania coal-mining circles. After being graduated from Lehigh University in 1887 and taking the degree of mining engineer there in 1888, he was for about two years assistant engineer of the Susquehanna Coal Co. at Wilkes-Barre. Then he returned to Lehigh, where for three years he was an instructor in mining, metallurgy and geology.

PROF. H. H. STOEK

From 1893 to 1897 he was assistant professor of mining engineering at Pennsylvania State College and from 1897 to 1909 was editor of *Mines and Minerals*, published in Scranton. In the latter field especially he occupied a prominent place not only in the coal-mining industry of Pennsylvania but throughout the United States. Professor Stoek had served as secretary of the Illinois Mine Rescue Commission, was a member of the Illinois Mining Investigation Commission and was a prominent leader in mine-rescue work. He was a member of the American Institute of Mining Engineers, an ex-president of the Coal Mining Institute of America, and was a member of the Institute of Mining Engineers of Great Britain, the Lake Superior Mining Engineers, the Illinois Mining Institute, the West Virginia Mining Institute and the Western Society of Engineers.

He published several volumes on coal mining, among these being "The Anthracite Coal Field," "The Economic History of Anthracite," "Subsidence in Mining," "The Education of Mine Employees" and "The Storage of Coal." He was particularly interested recently in the problems of the storing of coal and had just been appointed by the American Engineering Council to serve on a committee of engineers to make a detailed study of storage for commercial and industrial purposes. Professor Stoek was a widower at the time of his death. His wife was Miss Miriam Ricketts, of Wilkes-Barre, Pa., to whom he was married Dec. 20, 1894. He is survived by one daughter, Miss Leigh Stoek, Urbana, Ill. He was just past fifty-seven years of age and was born in Washington, D. C., Jan. 16, 1866.

Blames Hugh Willis for Herrin Murders

The second Herrin massacre trial is well on its way. Last week attorneys both for the defence and prosecution made their opening statements and examination of witnesses began. Five men, including Hugh Willis, state board member for the United Mine Workers, are on trial charged with the murder of one of the armed guards at the Lester strip mine near Herrin, Ill., last June when a mob accepted the surrender of 48 non-union men and slaughtered 22 of them.

C. W. Middlekauf, attorney for the state, in his opening speech blamed Hugh Willis for inciting the mob to murder the captives. Angus Kerr, head of the union's defence, declared "the prayer of the meek and lowly is that this jury shall decide the day has gone by when great corporations in their greed for profits can use gunmen in an effort to set up an industrial autocracy." Kerr, in a statement following the acquittal of the union defendants in the first trial, declared that acquittal to be just such a decision as he now seeks.

Kerr, who moved to Williamson County last autumn at the beginning of the Herrin trial, has just been appointed City Judge of Benton. The appointment is traced by political observers back through the hands of a Williamson County political boss who has been loyal to Governor Small.

Charges Bad Faith in Union Statements To U. S. Coal Commission

Walter Gordon Merritt, counsel for the General Policies Committee of anthracite operators, filed March 1 with the U. S. Coal Commission a protest against recent communications from the United Mine Workers of America, asserting that these statements are prepared not for the information of the commission "but for the purpose of disseminating sham and misleading arguments and conclusions through the medium of the newspapers."

Mr. Merritt's communication to the commission is as follows:

"Two statements from the United Mine Workers of America to the commission with reference to wages, prices, profits and production costs in the anthracite industry have come to my attention through the newspapers. We regret that these statements are not calculated to promote a fair understanding and a square deal between the parties involved or between them and the public. The circumstances show that they are prepared not for the use or information of the commission but for the purpose of disseminating sham and misleading arguments and conclusions through the medium of the newspapers.

"As you are aware, the producers of anthracite, in cooperation with the commission, are now preparing accurate data with respect to wages, cost of production, prices, profits, etc. This data will be the most complete and comprehensive ever collected on the subject and will include details as well as conclusions. The Policies Committee of the anthracite industry is pledged to a full disclosure of these facts and, so far as we know, none are being withheld. In due course this information will be compiled, examined and weighed by the commission and, we hope, made public. Statements on these matters before the data are available are obviously so unworthy of serious consideration that they cannot be inspired by a spirit of helpfulness.

"The real motive behind this propaganda is shown by the constant assertion in these statements that the operators are paying inadequate wages to maintain inordinate profits. The conclusive answer to this claim is the repeated willingness of the operators to arbitrate and the open insistence of the miners' union that there shall be no more arbitration. If the facts were as represented in this propaganda, the miners would willingly rely upon reason rather than force to sustain their claims and instead of inflicting privations on our people through anthracite strikes and coal shortages, would entrust their case to the peaceful adjustment of a fair and disinterested agency. The most antisocial practice in the anthracite industry today is the willingness to paralize the industry and injure the public by general strikes and intermittent outlaw strikes, when machinery for conciliation and arbitration exists. If the miners must issue statements, they should tell the public what they propose to do about this abuse instead of discussing costs and profits, concerning which they do not possess the facts.

"For these reasons we respectfully but earnestly protest against the irresponsible procedure now being followed by the miners' organization, while at the same time expressing our confidence that the commission will place no dependence upon this reckless propaganda. If the time has come when all statements of parties before the commission must be sent piecemeal to the press, the commission can at least rest assured that the operators' statement will be based on a careful conformity to investigated facts."

Secretary Davis Says Coal Radio Release While Commission Sat Was Coincidence

James J. Davis, Secretary of Labor, has written a reply to the remarks of Alfred M. Ogle, president of the National Coal Association, printed in *Coal Age*, Feb. 8, wherein Mr. Ogle characterized a radio release by the department as "a most unjustifiable and indefensible attack on the entire coal industry." Secretary Davis' letter, dated March 3, is as follows:

"Referring to your recent observations on the problems of the Coal Industry as copied in the *Coal Review* from *Coal Age*, I note that you very properly call attention to the general tendency of the press and public to misinterpret the preliminary report of the Coal Commission for want of more careful study and necessary knowledge to a correct interpretation.

"Later in the same interview you call attention to a recent radio release of the Department of Labor, and as your interpretation of same indicates a lack of familiarity with the functions and activities of this branch of the federal government, permit me to briefly outline same.

"The following constitute the activities of the Department of Labor: Bureau of Labor Statistics, Bureau of Naturalization, Bureau of Immigration, Children's Bureau, Women's Bureau, Housing Bureau, Division of Conciliation, Employment Service. Each of these bureaus and divisions are continuous in their activities and investigations, and are required by law to give the public the benefit of their findings as soon as possible.

"The survey release made by the Children's Bureau about which you complain as 'a most unjustifiable and indefensible attack on the entire coal industry, in addition that the said release can be regarded only as a serious courtesy to the President's Coal Commission,' was begun in 1921 and continued during the year 1922, before, during and after the great coal strike, and therefore began long before there was any coal commission considered.

"The broadcasting of a summary of the findings of the Children's Bureau was according to the regular schedule of publicity, and it was a mere coincidence that it was concurrent with the sittings of the Coal Commission.

"The purpose of all investigations of this department is to ascertain the *truth* about conditions affecting the welfare of all labor. That this survey began a year or more before the Coal Commission convened, and that it happened to be in relation to child welfare in the coal-mining camps, was another coincidence without the least intention or knowledge that a concurrent general investigation of the problems of the coal industry would be functioning before the survey was finished.

"I said that we want only the truth, and if we can be shown that said survey is in any way a perversion of the truth, let me assure you that a prompt correction will be forthcoming, and if it can be shown that any or all the investigators lent themselves to prejudice the truth about any condition found, the correction will be accompanied with such discipline that will prevent any immediate repetition in the further making of similar surveys.

"Therefore, Mr. Ogle, you will contribute something in the way of real constructive criticism if you will be good enough to furnish me with detailed proof of any errors made in this survey, with the assurance that they will be promptly checked by this department. I would prefer to have the checking done jointly by representatives of your National Coal Association and this department.

"It may further interest you to know that a complete copy of said survey has been filed with the Coal Commission.

"May I also suggest that the survey was believed to be the truth and if it (the survey) proves to be the truth, the publication or broadcasting of same as required by law could hardly be construed as an attack on the coal industry or an act of discourtesy to the Coal Commission, but rather as an aid to the further education of the public showing some of the contributing causes of unrest in some mining districts, that show the necessity for the thorough study now being conducted by the President's Coal Commission.

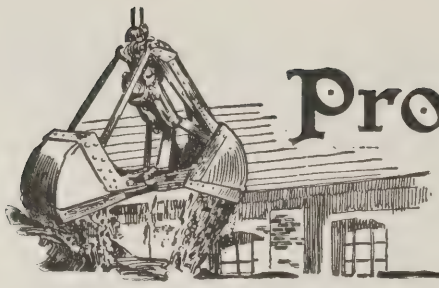
"May I also say that the Coal Commission is a temporary but concentrated effort to develop the facts of the industry to meet an emergency, while the Department of Labor, through its various activities, is a permanent institution to gather, tabulate and correlate these facts from time to time for the public information, which of course includes Congress, commissions, federal departments, employers and labor generally.

"The Department of Labor is not a perfect institution, and there is room for much improvement, therefore constructive criticism is always welcomed, as the only desire we have is to turn the light on various industries in a helpful way, so that the causes of discontent may gradually be removed and the friendly relationship of employer and employee be insured by such removal."

Says Miners Would Take 20 per Cent Cut in Wages if Assigned Cars Were Abolished

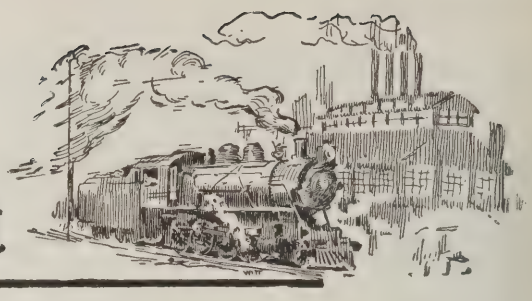
Arguments in the assigned-car case were concluded on Friday, March 2, before the Interstate Commerce Commission. Attorney Ballard, for the National Coal Association; Attorney Ropriquet, representing Illinois operators; Attorney Boyle, the Southern Ohio Coal Exchange, and Attorney Liveright, of the central Pennsylvania operators, all argued against the assigned car. Attorney J. J. Kintner, of Lock Haven, Pa., appeared on behalf of District No. 2 of the United Mine Workers of America in opposition to the assigned car in all of its phases. Mr. Kintner stated that if it were not for the assigned car there would be a big reduction in the production cost of coal and also a big reduction in miners' wages. When asked by Commissioner Potter how much reduction in wages would result, in his opinion, from the abolition of the assigned car, he stated that he believed that the miners could take a 20 per cent reduction if the assigned-car practice were discontinued.

Mr. Kintner said that the railroads in the district for which he was speaking have used the assigned and private car to discriminate against union labor. He made public a letter dated Feb. 10 to Dr. Edward T. Devine, of the U. S. Coal Commission, from John Brophy, president, District No. 2, United Mine Workers of America, in which the assigned-car evil is brought to the attention of the coal commission with a request that the practice be abolished.



Attorneys Gutheim and Bronson appeared on behalf of the railroads and James Carmalt on behalf of the owners of private coal cars. Messrs. Gutheim and Bronson's argument was to the effect that the railroads could not get their coal in an orderly manner without the use of assigned cars. Attorney Carmalt took the position that privately-owned coals cars augment the general supply and he did not claim for them any preferential or special service.

Senate Gets Report on Anthracite Impurities; Walsh Presents Coal Inspection Bill



The U. S. Bureau of Mines transmitted to the Senate March 2 a report in response to a resolution adopted by that body calling for information relative to the extent of misbranding and impurities found upon investigation to be contained in anthracite being marketed. The bureau states that although its studies show that much high-ash coal is shipped and that many letters have been received from the anthracite-using districts complaining of the quality of coal, it "has made no special investigation that would enable it to say what proportion of such coal carries an unreasonable amount of ash."

The report adds that there are no generally accepted standards for comparison; that the determination and maintenance of grades for coal depends upon extensive sampling and analysis, and a suitable inspection system and competent force. The bureau expresses the opinion that the recommendation by the Secretary of the Interior in 1919 proposing the establishment of a coal-inspection system "would best meet with the needs of the case."

Senator Walsh, author of the resolution, introduced a bill in the Senate March 2 along the lines suggested by the Bureau as above stated. The measure was referred to the Committee on Mines of the Senate.

Production and the Market

Weekly Review

After the slump in the holiday week production of bituminous coal recovered last week and reached the 11,000,000-ton mark. Prices, however, continue their downward trend, *Coal Age* Index dropping nine points in the week to 279 on March 5, with the average spot price at $3.38. Consumption of soft coal has been at a high level for the past three months, the immediate result of the business revival and the domestic demand. The output of bituminous coal has been held in check by car shortage in the East and lack of demand west of the Mississippi.

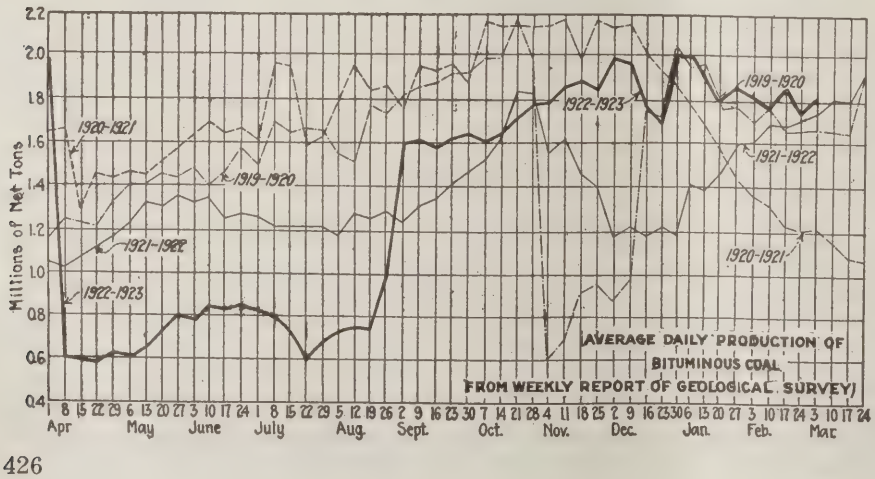
That prices on the whole have been slumping for the past two months does not tell the whole story, for in the process of readjustment the market on high-grade low-volatiles in the East has been more resistant than on the lower grade steam coals or on the high-volatiles in the Midwest When all the accounts have been checked up for this winter it will be found that on the whole production has been in excess of consumption and that there has been a continuous if somewhat diminishing stream of soft coal going to storage, which fact accounts for the steady softening of the market.

It is quite evident that no satisfactory basis for contracting for the next coal year will be reached until well after April 1. Buyers are waiting to see how the railroads carry the load that general business is putting on them and how competition between the various fields cuts prices when the cold weather demand is out of the way.

Demand from Foreign Countries

The demand from foreign countries for American coal grew in strength early in the week, only to fall again following a sharp advance in steamer rates. For a few days quotations for Southern coals were slightly stronger, but they soon relaxed. Late last week it was reported that from six to twelve steamers had been chartered to carry coal from Hampton Roads or other Southern ports across the seas, most of the chartering being done in London.

There is plenty of coal throughout the Midwest. In Milwaukee the demand for anthracite or its substitutes remains strong. Dock supplies in that city are short. Increased industrial activity in the mountain states is absorbing a 60 per cent production at most of the Colorado and Utah mines.



Operations in central Pennsylvania are suffering from poor car supply, embargoes on shipments into New England and dull market. Most operators are anxious for contract business. The majority of contracts closed have been renewals. Buyers continue to hold off, believing they will do as well in the open market as by signing up at the current quotations.

New England Situation Quiet

Market conditions in New England are quiet. Consumers, especially large users, are marking time. Both all-rail and by water there is ample coal offering, and there is every indication the supply will exceed the demand during this month and April.

"Present estimates of soft-coal production in the week ended Feb. 24 indicate a total output of 10,332,000 net tons, including coal shipped, mine fuel, local sales and coal coked," says the weekly report of the Geological Survey. "This is 100,000 tons less than the revised estimate for the week preceding, but the daily rate of output, considering the observance of the holiday in some districts, was essentially unchanged.

"That the downward trend in production is checked is further indicated by preliminary reports of cars loaded during last week (Feb. 26-March 3). These show 42,732 cars loaded on Monday, 32,984 on Tuesday, 31,150 on Wednesday, and 28,398 on Thursday, the total for the four days being 7 per cent greater than for the

a) Subject to revision. (*b*) Revised from last report..

corresponding part of last week. The indicated total output for the week therefore is about 11,000,000 tons."

Moderating weather conditions have affected the anthracite situation. While there is a continued demand for the domestic sizes it is believed the crisis has been passed. Repeating their requests of a few weeks ago and later asking that the orders be reinstated dealers from many faraway points have cancelled orders for the domestic coals.

Coke production decreased during the week ended Feb. 24 for the first time in many weeks. The total output estimated by the Geological Survey from reports of cars loaded by the principal coke carriers and in part on reports of producers was 370,000 net tons, as compared with 378,000 net tons in the week preceding.

Midwestern Market Quiet

Nothing happened during the past week to liven up the Central Western market to be viewed from Chicago. Soft weather kept domestic demand quiet. This, however, was not sufficient to decrease the general supply enough to hoist the price of steam sizes. Nobody demanded coal of any sort. Big steam buyers laid back on their contracts so that little spot coal was traded to the advantage of the operator. A good deal, on the other hand, got into difficulty and had to be dumped at weak prices.

Franklin County operators, best fortified with contracts, were able to maintain circular prices pretty well on big lump while weaker grades of coal from surrounding properties were undercutting them 50@75c.

Central Illinois, with all too good car supply, could not maintain its $3.50 price on 6-in. lump. Some of the country trade took a thin stream at that price but more of it sold for $3.25. Screenings from that field went down to $1.25 along with the fine sizes from the Standard district east of St. Louis, where cars were just as numerous. Several central Illinois mines have already shut down, along with about 25 per cent of Indiana mines, for lack of market.

Illinois and Indiana coals continue to have all the business there is in the Midwest because of the continued transportation jams at the Cincinnati and Toledo gateways.

Dropping off of railroad tonnage in all Illinois fields helped in the general sogginess. Car supply ran little better than two days a week in any of the southern or southwestern Illinois fields. Cheaper coals sold through the St. Louis market with less pushing than superior grades, just

* Net tons, f.o.b. mines. † Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 279, Week of March 5, 1923. Average spot price for same period, $3.38. This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions each of slack, prepared tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

as they have been selling for two or three weeks. The Standard district may not be making much money but it is getting most of the available business with 6-in. lump moving at $3@$3.25, steam egg and nut at $2@$2.25 and screenings at $1.30@$1.40. On that market a small volume of Mt. Olive lump has been selling at $4 around the city and $4.50 to the country. Mt. Olive screenings bring $1.75. But buying of every sort of coal is in small quantities. St. Louis is getting a little hard coal for the first time in several weeks and Arkansas semi-anthracite is again coming in.

Kentucky Is Not Discouraged

Western Kentucky operators are getting enough business to absorb most of their output, even though it takes some lively pushing. Dealers and most large consumers with small stocks still on hand are using up those supplies steadily now and are buying cautiously. But railroads, with a heavy volume of freight to move, are buying with some freedom. This is largely contract business, however.

The outstanding feature of the present situation in Kentucky is that it is much better than last year. There are no big stocks in retailers' hands to interfere with present or spring business. Industrial consumption generally is much better in all sections than it was last spring. Prices of coal are much better than those of last spring and there are no labor, railroad or other serious troubles in prospect.

Milwaukee jobbers are worried so by the traffic jams at Eastern gateways that they are now beginning to cancel bituminous orders which they had made for inland customers. Six weeks' deliveries are about the best that is promised them. The recent reduction of 75c. on Illinois domestic coal has not yet been reflected in Milwaukee because so much coal from that state's fields which was bought at the old prices is still on hand.

Around the Head-of-the-Lakes nobody is worrying much. Anthracite stocks on the docks are swept out almost to the last ton. Not since 1902 has such a clean-up been observed. But there is just enough coal in the bins of consumers and just enough of briquets, coke and other substitutes available to prevent complaint.

Estimated stocks of soft coal on the Superior docks Feb. 1 totaled 1,175,000 tons, which was low. Shipments off the docks have been steady, especially during February, which was 40 per cent better than January, but slow since then and weak prices are still the rule.

West Does Some Business

In the mountain states of the West, coal trade is not so dull in spite of the return of soft weather. A general pick-up in industrial activity is absorbing a 60 per cent production at most of the Colorado and Utah mines and prices have remained fairly level. For once there is a place for the lignite slack of northern Colorado and the steam sizes of most other Colorado, Wyoming and Utah coals find ready acceptance.

In and around Kansas City, however, the market is quiet as a Midwestern village on a hot Sunday afternoon. Industrial demand is fair but warm weather has killed the domestic call and such surpluses of prepared sizes of Kansas and Oklahoma coals are piling up that the old, old question "what to do?" faces almost every operator. The list prices on domestic sizes have not been changed but undercuts, of course, are being made.

Ohio Fields Show Greater Strength

More strength is showing in all Ohio fields due to curtailed output rather than to consumption. Buying on the part of both dealers and steam users in and about Columbus is general although orders are generally small. Dealers are not anxious to buy heavily, because of the lateness of the season and also because of the possibility of reduced prices on prepared sizes. Heavy reductions in lump and egg coals are looked for during this month.

General manufacturing concerns are using up reserves accumulated some time ago and are now buying from hand to mouth. Contracting is reported on a small scale; it is not expected to be active until after April 1. Embargoes are holding up shipments. Empties are slow in being returned and mines as a rule are operating but a day or two each week. The Hocking Valley is producing about 20 per cent and the same figures are reported from other fields.

Production in the eastern Ohio mines was cut into during the week ended Feb. 24 by the holiday and inadequate car supply. The output was 253,000 tons, the lowest of any week since the strike.

Operators in West Virginia are beginning to look forward to the opening of the Lake season as affording additional outlets for their product. Few if any mines along the Chesapeake & Ohio R.R. are getting more than a day and half's car supply per week. Mines along the Norfolk & Western are producing at the rate of about 35 per cent of capacity.

Car supply in Virginia shows a slight improvement, while the mines in northeastern Kentucky are still limited in output owing to poor car supply.

The Pittsburgh market remains steady, rather because of poor car supply than demand. Consumption has increased in the steel industry as mill operations have been increasing steadily for two months. Demand for domestic lump increased somewhat because of the cold snap.

Car supply along the Pennsylvania R.R. in central Pennsylvania is declared by operators to be worse now than at any time during the winter. Many operators have closed down rather than do business on the present basis. Conditions at the mines reached by the New York Central and B. R. & P. railroads are somewhat better.

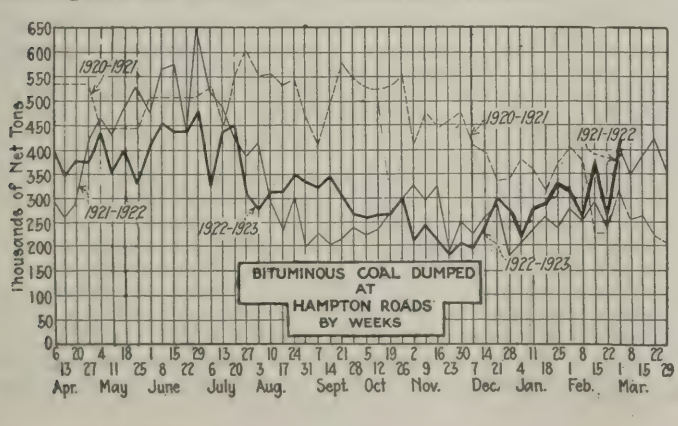
There is some activity in the contract market at Buffalo. Figures proposed now are $2.75@$3 for Allegheny Valley mine-run, the lower figure appearing most often. The market is quiet and no immediate recovery is looked for.

New England Bituminous Market

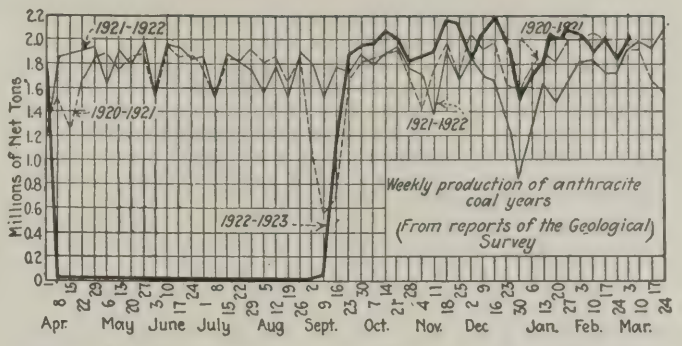
The bituminous market in New England territory is extremely quiet. Large consumers have comfortable reserves and with respect to future supply are simply marking time. Both all-rail and by water there is ample coal offering, and there is every indication the supply will exceed the demand during March and April.

All-rail there are still embargoes in effect that curtail deliveries here from several districts, but there is clearly enough coal moving to take care of current light requirements. Pressure to get steam coal for domestic use has eased off very materially, and with the approach of mild weather this sort of demand will cease almost entirely.

Operators of central Pennsylvania are striving not only to sell spot coal for March but also are making a thorough canvass for contract tonnage to see them through the summer and autumn. Buying in New England will be slow starting, and so much depends upon the Hampton Roads situation that it will be several weeks, if not months, before the Pennsylvania grades settle down into a season basis as to price. Contracts are being offered all the way from $2.50 to $4, depending upon grade, but consumers are counting upon either a marked reduction among all-rail coals or purchases from Hampton Roads, where prices have already dropped to last autumn's level.



Accumulations continue at Hampton Roads with only mild demand even for Navy standard grades. The best fuel at $6.25 is an easy purchase, and the less favorably known coals can be had at $6, in each case per gross ton f.o.b. vessel. Tonnage is moving in measurably good volume on contract business coast wise, but offshore and along the line and to the west the amount of coal absorbed is relatively light. For distribution inland from Providence, Boston and Portland there is only scattering inquiry. Prices range upward from $9.25 per gross ton on cars, but the market generally is spotty and quotations fluctuate.



Ice conditions in Long Island and Vineyard sounds have seriously interfered with boats and for nearly a week the Cape Cod Canal was blocked with ice in Buzzards Bay. Higher temperatures already are having their effect and no further trouble is expected. With boats moving freely there will be ample coal for all purposes.

New York Shippers Look to Lake Opening

Water shipments from the New York terminals to New England increased somewhat but heavy ice in the harbors interrupted the unloading of the vessels. Local shippers look for a much brisker market following the opening of the Lake season. There were 2,108 cars at the New York terminals on March 2, as compared with 2,841 cars on Feb 23.

Consumers in Philadelphia appeared to be less interested in the soft-coal market than during the previous week. Producers of high-grade Pennsylvania coals on the other hand, assert that they are hard put to fill all the orders they have in hand, and insist that the so-alled market prices do not accurately represent the situation. Shippers say that car supply is inadequate and that they could find a market for a great deal more coal if cars were available.

Demand at Baltimore is poor. There was more than 100 per cent increase in the amount of coal exported from Baltimore during February over that shipped during the previous month, the tonnage during February amounting to 10,424 tons including 1,212 tons in bunkers, as compared with 4,379 tons in January, including 260 tons in bunkers.

Anthracite

The anthracite market is much easier. New York State Fuel Administrators believe the crisis has passed and that only unusual conditions will again create a shortage. The purchase of substitutes has almost fallen into the discard, neither dealers or consumers taking any unless absolutely necessary. Dealers in Philadelphia are endeavoring to create reserve stocks notwithstanding the nearness of April 1.

The hard-coal situation at Baltimore is easier.

The production of anthracite in the week ended Feb. 24 was practically the same as in the week before and is estimated at 1,838,000 net tons, including coal shipped, mine fuel, local sales, and dredge and washery output, says the Geological Survey. Production was at a low rate on Washington's birthday and Saturday. Early returns on car loadings during the first four days of the week Feb. 26-March 3 indicate production at the rate of 2,100,000 tons for the week.

How the Coal Fields Are Working

Percentages of full-time operation of bituminous coal mines, by fields, as reported by the U. S. Geological Survey in Table V of the Weekly Report.

	Jan. 1 to Apr. 1, 1922 Inclusive	Sept. 5 to Dec. 30, 1922 Inclusive	Jan. 1 to Feb. 17, 1923 Inclusive	Week Ended Feb. 17, 1923

Foreign Market And Export News

Foreign Demand for British Coal Still Strong; Slight Decrease in Production

The Welsh market continues steady. France is buying heavily while business with Italy is substantial. South America, India, coaling stations and Egypt have taken heavy tonnages recently. A feature of the market is the sustained Continental demand.

The market in the north of England remains very strong. The increasing scarcity of fuel in Germany, France and Belgium is indicated in the pressing demand from these countries.

Production in the British mines during the week ended Feb. 17 was officially reported at 5,560,000 tons, says a cable to *Coal Age*. This was 7,000 tons less than the previous week, and the smallest tonnage produced since the first week of the year, when it was 4,384,000 tons.

In an effort to relieve the dock congestion at Cardiff the coal tippers and trimmers have agreed to experiment with the three-shift system for three months. Before the war these men worked three shifts of eight hours each, but for the past five years they have only worked two shifts of eight hours. With the renewed demand for Welsh coal the docks have become greatly congested.

During the week ended Feb. 9 there was an increase of 72,172 tons to 618,034 tons in the British Channel exports. Exports from Cardiff and Newport, in tons, were:

France	122,302
Italy	97,074
South America	58,531
Spain	29,298
Portugal	13,005
United States of America	37,687
Canada	3,518
British coal depots	87,072
Other destinations	54,526
Total	503,013

Business Brisk at Hampton Roads

Business has been brisk at Hampton Roads. The market stiffening in consequence, and increased coastwise movements gave promise of better conditions in the trade. A generally stronger tone was the feature of last week's market.

The strengthening of prices was regarded by shippers as only temporary. The belief was general that prices are due for a still further slump, and that the consequence will be ability of American shippers to get back into export business which has been neglible at Hampton Roads.

General shipping showed improvement, bringing activity to the bunker trade. All piers operated at full force, with stocks somewhat cut down but with movement from the mines improving.

Raise Wages in French Mines

At a conference held at Douai between the mine owners of the Nord and Pas-de-Calais and the delegates of the Federation Nationale des Travailleurs du Sous-sol, the non-communist miners' organization, whose members had remained at work, it was agreed that the wages of adult workers should be raised, as follows: Two fr. per shift as from Feb. 1, retroactively, and 1 fr. 25, as from Feb. 15. The wages of boys and girls are to be proportionately increased.

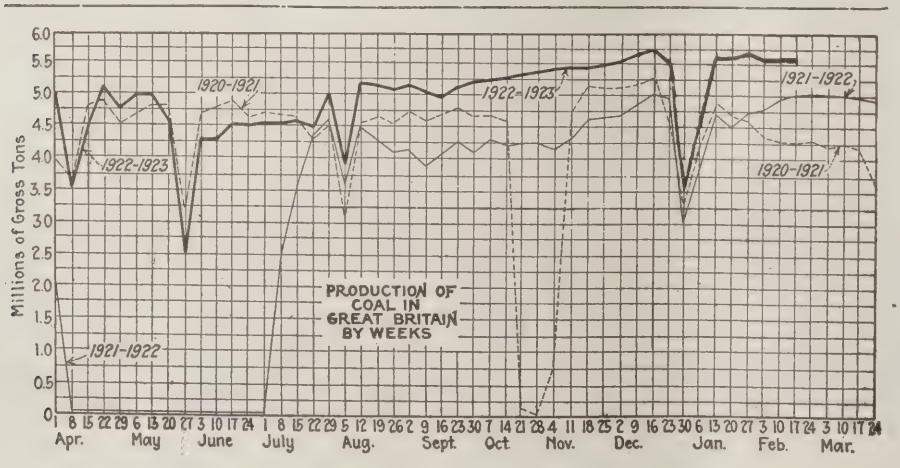
The increases restores the wages in the Nord and Pas-de-Calais to the scale in force in December, 1921.

To the delegates of the same faction of miners in the Loire coal fields the mine owners have offered an increase of 3 fr. per shift, which was the decrease in wages put into effect in August, 1921.

French Miners Formulate Demands

The Federation Unitaire des Travailleurs du Sous-sol, the communist organization of French miners, early in February formulated the following demands, applicable to all French coal fields.

"Return of wages to their maximum level since the armistice plus 1 fr. 50 per shift for underground and 2 fr. 50 for surface workers.



"Incorporation in wage rates of the indemnity for high living costs.

"Creation of workmen's committees.

"Suppression of tax deductions from wages."

Strikes and the lack of coal as a result of the interruption of shipments from the Ruhr have caused a scarcity of French industrial coals and the government has given instructions that the railway requirements must be met first and then the ordinary industrial wants.

Between Jan. 19 and the middle of February, France received practically no fuel shipments from Germany, although it was expected they would be resumed shortly.

Italian Coal Imports in 1922

Coal imported into Italy during 1921-22 for the Italian State Railways and the Ministry of Finance totaled 3,731,-604 tons, against 1,557,280 tons during the year 1913-14. The coal used during the past year on the Italian state railways totaled 184,955 tons, and in the Italian navy 184,955 tons. British fuel shipped to Italy amounted to 550,332 tons; American, 182,306; while German coal imported on reparation account totaled 2,792,761 tons.

News Items From Field and Trade

ALABAMA

The Sartain-Boyer Coal Co., with headquarters in Jasper, has been incorporated with a capital stock of $150,000, of which $126,000 has been paid in. Incorporators are Charles M. Sartain, Mrs. E. F. Guy, F. M. Sartain, J. H. Boyer and Frank Boyer. The company will engage in coal mining in Walker County.

John Hays Hammond, chairman, and **Thomas R. Marshall** and **Clark Howell**, associate members of the U. S. Coal Commission, arrived in Birmingham for a visit of several days on March 7 and will make an investigation of the several phases of the industry in this district.

ARKANSAS

Sept. 10 has been set as the date for the **new trial of the suit of the Coronado Coal Co. against the United Mine Workers of America** in the United States District Court at Ft. Smith. The Supreme Court of Arkansas last summer reversed a verdict of $600,000 that was obtained by the coal company. The suit grew out of the destruction of property of the Coronada Coal Co., the Mammoth Vein Coal Co. and a group of other mines, known as the Bache Denman Coal Syndicate, in the summer of 1914, during the labor troubles in the Hartford Valley of Sebastian County.

CALIFORNIA

The educational committee of the Woman's Auxiliary of the American Institute of Mining and Metallurgical Engineers have announced **a free scholarship worth $500 a year** to commence next autumn. It is open to but one citizen desirous of studying for a degree in mining or metallurgy at a standard school of mines. Candidates may send their names to Mrs. Horace V. Winchell, 728 W. 28th Street, Los Angeles.

COLORADO

D. Harrington, supervising mining engineer of the U. S. Bureau of Mines, during the middle of February, spent several days at Dawson, New Mexico, investigating the recent explosion in the mines of the Phelps Dodge Corporation, which killed 122 men.

Wood & Weber, consulting engineers, of Denver, have been entrusted with the design of the **power plant and hoisting equipment for the mine of the Alamo Coal Co.**, near Walsenburg. A 1,250-kw. turbo generator has been purchased and will be installed in the summer, along with the necessary boilers and auxiliary equipment. A large electric slope hoist is yet to be bought.

ILLINOIS

Coal rights under 1,300 acres of land north of the Sangamon River, near Springfield, a part of the Carpenter estate, **have been sold to the Midland Counties Coal Co.**, allied with the Peabody interests. The coal rights brought the sum of $16,500. The Midland Counties Coal Co. was incorporated Dec. 15, 1913, with capital stock of $5,000. The incorporators were Arthur W. Underwood, Nathan E. Smyser and Charles R. Young. The company certified to an increase in its capital stock from $5,000 to $3,000,000 Dec. 17, 1913. The certificates were signed by Arthur Woodward as president and Frank M. Wright as secretary. The offices of the company at present are at 72 West Adams Street, Chicago.

The Southern Mining Co., of 214 North Vermillion Street, Danville, has been incorporated with a capital stock of $150,000. The incorporators are Walter L. Millner, Richard Y. Hoffman and Kenneth M. Fiske.

Mike Miller, 45 years old, was killed and five other miners were injured when they were caught under a fall of coal at the mine of the Franklin County Coal Co., at Benton, Ill. The men were working on the night shift and were placing props in the mine when the accident happened.

The Clover Leaf Coal Co., 1201 Public Square, Marion, has been incorporated with a capital of $150,000 by R. B. Mitchell, H. W. Ragel and Wm. H. Warder.

The Clyde Coal Co., Cicero, has increased its capital stock from $20,000 to $25,000.

Work will be started in the next few weeks on the **erection of a new five-track steel tipple** at Mine No. 1 of the Wasson Coal Co., at Harrisburg. The new tipple will be modern in every respect, will be equipped with the latest machinery known in the coal preparation business and will handle over 3,000 tons per day. The new tipple will replace their old four-track tipple and will be the most modern in the district. Machinery made by the Jeffrey Mfg. Co. will be installed in the new plant and work will be started not later than April 1.

The workings of mine No. 18 of the By-Products Coal Corporation at West Frankfort were damaged recently when a fire was discovered raging on the inside of mine. The portion of the mine in which the fire was discovered was immediately sealed off in an attempt to smother the flames. An estimate of the amount of loss from the fire has not been announced by the company.

The offices of the Franklin County Mining Co. at Benton suffered a recent loss by fire. The fire started from an overheated stove and only by prompt action on the part of the Benton fire department was the building saved.

INDIANA

Operators of coal mines at West Clinton, owned by the Jackson Hill Coal & Coke Co., assert that additional demands made by 800 miners on working conditions has resulted in the men quitting work and **tying up the operations of the three mines owned by the company**, which have a daily capacity of 5,000 tons. The officials said that about a month ago the miners in one of the plants made demands to be transported to work and that the time of working commence when the miners arrive at the bottom of the shaft. This dispute was settled but recently the workers made additional demands of a similar character and called out the workers of the other two mines in the grievance, officials of the coal company declare.

The Star Coal Co., Jasonville, has been chartered with a capital of $20,000. The directors are: W. C. Warrick, I. S. Ritchey, Monroe Beatty and Robert E. Mason.

The Mt. Pleasant Coal Co., Terre Haute, has increased its capital from $25,000 to $50,000.

Coal has been reached in the No. 5 vein at the shaft of the Deep Vein Coal Co. south of Princeton, at a depth of 420 ft. The vein is 8 ft. 9 in. thick and is a fine grade of coal. The company expects to open one of the largest and most modern mines in the state and has a block of leases of more than 5,000 acres. The new shaft is concreted to a depth of more than 60 ft. down to the solid rock. A steel tipple will be erected and when the mine reaches full production more than 1,000 men will be employed. Switches have been laid and during the summer these will be connected to an interurban electric line. The opening of the Deep Vein mine is **the first of several new mining operations** started in that vicinity. The coming summer will see a greatly increased coal output from the Gibson County mines. **The Francisco Coal Co.** now has two of its mines in operation and work of sinking the shaft for the third will start during the summer. **The General Fuel Co.** is proceeding steadily toward putting its new mines in operation. One is virtually completed and the shaft of the second is nearly finished. The company will sink a total of four mines.

Can a miner who is driven out of a community by United Mine Workers collect damages from the union? This is one of the questions involved in the suit of John W. Smith, of West Frankfort, Ill., against Local 1,005 of the union for $3,000 damages and for a permanent injunction to prevent that local from molesting him at work. The suit has been transferred in the federal court from Indianapolis to Evansville and will be heard by Judge A. B. Anderson some time in April.

IOWA

The Lanning Coal Co., Oskaloosa, has been incorporated with capital of $13,000. F. D. Lanning is the president and C. E. Lanning, secretary-treasurer.

KANSAS

A special dispensation by the present board of District 14, United Mine Workers of America, upon assuming office the first of this year, granting relief from a $15 fine imposed upon miners of the district who refused to walk out during the general strike last summer, has resulted in **1,300 of the 2,000 men liable to the fine returning to the union**, Harry Burr, district secretary and treasurer, has announced. Twenty new locals have been chartered in the district this year, according to Mr. Burr. The dispensation ended March 1.

Representatives of the operators and miners of Kansas will meet in Kansas City some time before March 9 **to establish a machine scale** for Kansas, where none now exists.

The Sheridan Coal Co. of Pittsburg, the largest company in the Southwest district not in the Southwestern Interstate Coal Operators' Association, **has just signed a contract on working rules with the United Mine Workers of America.** The Sheridan company withdrew from the organization during the general strike and operated some of its mines under a co-operative arrangement with some of its miners.

KENTUCKY

The Western Kentucky Coal Operators and representatives of the United Mine Workers of District 23 will meet in Louisville March 12 **to negotiate a new wage scale**, it has just been announced in Louisville. The present scale, which expires April 1, calls for a maximum of $6.95 a day for inside men; 74 to 76c. a ton for machine-mined coal and $1.05 for picked coal. Lonnie Jackson, district president of the mine workers, said he expected no trouble in reaching an agreement.

The Hazard Coal Operators' Association is **investigating the possibilities of using radio** receiving and sending sets at Cincinnati, Lexington, Louisville, Hazard and other points with a network of receiving sets through the field to aid the operators in keeping posted on what is going on. Telephone service between the fields and markets has been far from satisfactory. A committee composed of W. E. Davis, of Lexington; James Bonnyman, of Cincinnati, and Prentice Burkingham, of Cincinnati, was named at a meeting in Lexington on Feb. 16, to look into the matter.

Two five-track tipples are now in process of construction at the mines of the **Gibraltar Coal Mining Co.** at Central City. The tipples are exact duplicates designed and to be erected by Allen & Garcia. They are equipped with shaker screens, loading booms and picking tables to make these coal preparation plants highly efficient and of ample capacity. The structures are to be of steel with corrugated zinc siding and roofs of the same material having areas of corrugated wire glass over the picking tables.

Captain Frank Horn, superintendent of the Coneva Coal Co., **was shot and killed** presumably by Monroe Kilborn and whisky runners at Kilborn's home near Hazard, Feb. 16. Kilborn, who had been discharged by the company, is alleged to have brought whisky into camp. Captain Horn went to Kilborn's home in connection with the liquor running, and is said to have been shot eight times. His gun was found by his body, and had not been discharged.

Reports from Hazard, Letcher and other eastern Kentucky counties are that congestion on railroads serving Kentucky is such that **many embargoes have been placed** and sidings in the fields are loaded with cars waiting to be turned over to Northern roads, resulting in movement from mines in the Elkhorn-Hazard districts being very slow. Movement of empties into the fields is very light and loading has dropped to a comparatively low basis.

The Illinois Central R.R. has started grading for its new eighteen-mile connection in western Kentucky from Central City to Madisonville, which will run through a rich coal district and open a number of new mines, at the same time giving shippers in the Madisonville section improved outlet.

Lonnie Jackson, president of United Mine Workers, District 23, western Kentucky, is **arranging for a conference** in Louisville on March 12 with western Kentucky coal operators relative to deciding **on a new wage scale**, the present two-year contract expiring April 1. During the big mine strike last spring western Kentucky continued operation under a two-year contract which contained a clause preventing a strike at that time. The present scale calls for a minimum of $6.95 a day for inside men; 74 to 76c. a ton for machine-mined coal and $1.05 for picked coal.

The state's $1,000 reward for the capture of the murderers of Captain Frank Horn, manager of the Coneva Coal Corporation, has been **collected by a relative of the two killers and will be used in their defense.** Ira Kilburn, the brother of one of the men and half-brother of the other, rode into Hazard Feb 26 with the two riding behind him. He formally surrendered them and collected the $1,000.

The world's production record for any coal mine is now claimed by the **United States Coal & Coke Co.** for its Lynch mine, in the Elkhorn seam at Lynch. The mine, which is a drift operation working 40 shortwall cutting machines and 24 locomotives, hauled out and loaded 12,820 tons one day in February.

Suit has been filed in Louisville by the W. A. Wickliffe Coal Co. against the Kentucky Wagon Mfg. Co. for $8,888.05, representing eight notes executed by the company in 1921 in payment of coal shipped to its plant at Louisville. The company has been reorganized as a part of the National Motors Corporation and has been involved in a number of suits of late.

Trial started at Henderson on Feb. 19 of Ollie Gibbons and Mrs. Gus Noffsinger, in connection with the killing there of Gus Noffsinger, manager of the Southland Coal Mining Co., in December. Mr. Noffsinger was killed with a hammer in his own yard.

R. C. Parsons, superintendent of transportation of the Louisville & Nashville R.R., will be **chairman of the new rating commission** to apportion cars to the various mines served by the L. & N. Who the other two will be has not as yet been decided, but they will be railroad men. The commission will make a personal inspection of all mines served by the road and will cover Kentucky, Tennessee, Illinois, Virginia and Alabama.

Nine miners and Albert Scott, assistant state mine inspector, were **injured in a gas explosion in the mine of the Madison Coal Corporation,** within two blocks of the business center of Central City, Feb. 23. Two of the men were injured seriously. Scott and the miners were making an inspection of the mine and were in an abandoned mine when one of the men is said to have lighted a match. The explosion followed. The men were able to get to the bottom of the shaft unaided. The mine was not damaged.

Alben W. Barkley, Representative from Paducah, who is after the Democratic nomination for governor, in a talk at Danville on Feb. 19 said he **favored production tax on all Kentucky coal** based on the **value at the mine.** He argued for exemption of real estate taxation except for school and road use, although he admitted that this was impossible at this time.

MINNESOTA

The Northwestern Coal Dock Operators' Association has filed with the United States Coal Commission an interesting statement of the coal situation as the members view it. They declare flatly that the entire cause of extreme prices on coal at all times has been due to the railroads failing to function adequately because of their lack of cars and of locomotives. The statement is from H. E. Smith, of St. Paul, as president of the dock association, and declares that there cannot be a coal shortage, except on account of a strike, for the reason that the mines are so overdeveloped that they can produce a great deal more coal than can be consumed.

The fight in Minneapolis and St. Paul over the award of the water power of the high dam in the Mississippi River to the Ford Motor Co. interests has resulted in some interesting reports as to Mr. Ford's intentions. The latest is that he **will build a railroad from the docks at Duluth and Superior to St. Paul,** for the purpose of hauling his own freight. The road is to be for freight only. Ford interests also have been negotiating for the purchase of a coal dock at Duluth.

MISSOURI

Two bills before the Missouri State Legislature are being opposed by the coal men of the state. One would require operators to provide a shower bath with hot and cold water for every ten men employed in a mine, and a wash basin for every three men. The other would levy 1c. on every ton of coal mined to support the state mine inspection department, instead of the two mills levy now in effect. Both bills have passed the House and are before the Senate. The bathhouse bill is especially obnoxious because of the inaccessibility of water to many mines of the state. Another bill of interest to coal men is one requiring an inspector for every mine in the state to examine the mine before the men are permitted to enter. An inspector is now required only at mines known to be gaseous.

A company has been formed at Glasgow to develop a coal mine on a tract of land about three miles from the city, and work on the project will start soon. A railway switch will be built to the mine so that the coal can be loaded at the pit and shipped out from there to the markets.

A conference of representatives of operators and miners of Missouri, in session in Kansas City since the end of the wage conference, Jan. 8, has adjourned **without reaching any agreement to revise the machine working conditions.** The matter has been checked up to individual operators and the miners in their employ, with the understanding that if they agree to any changes their decision shall be referred to the Southwest Mine Operators' Association for approval or disapproval.

NEW YORK

Plans for recapitalization of Burns Bros., approved by a special committee of directors in December, **were adopted** by the full board Feb. 28 and put in shape for presentation to the stockholders at their meeting at Jersey City, March 31. Ratification of the plan by the stockholders will give the company a capitalization of $10,000,000 in preferred stock and 500,000 shares of common stock. On the basis of present holdings there will be outstanding 80,944 shares of preferred and approximately 350,000 shares of common. The reorganization provides for the retirement of the total amount of $1,208,000 of 7 per cent cumulative preference stock at a figure of $120 plus accrued dividends and the retirement of $2,975,000 of the 7 per cent cumulative preferred stock. As Burns Bros. has no funded debt or outstanding notes, this makes the 80,944 shares of Class "A" common stock a first lien on the company's assets.

An executive conference, in which General Goethals, State Fuel Administrator, district administrators from all over the state, and John F. Bermingham, president of the Delaware, Lackawanna & Western Coal Co., and D. Fred Williams, vice president of the Hudson Coal Co., took part, was held at the office of the State Fuel Administration at 165 Broadway, New York City, March 1. The total number of emergency complaints investigated during February was 7,163, it was announced, and in 5,868 cases aid was given by the Fuel Administration. January's complaints totaled 4,495, with aid given in 3,275 cases.

W. S. Simms, who has been associated with the Gano Moore Coal Mining Co., the Crescent Fuel Co. and the Fort Dearborn Coal Co., has joined the forces of the **Cory Mann George Corporation.**

Michael Tuck, president of the Titan Fuel Corporation, 42 Broadway, has gone to St. Petersburg, Fla., for a month.

NORTH DAKOTA

The Center Coal Co. has been incorporated by H. O. Hagenston, of Aberdeen; S. L. Houser and Robert Plaggmeier, of Leith, its purpose being to develop lignite production at Leith. The company has been working its property for some time and now it is being shaped up for further development. Over $15,000 in new equipment has been installed this summer and the company is now selling between 400 and 500 tons in this city alone every month.

OHIO

The Merrimac Fuel Co., with M. F. McDermott as president, W. J. Quinn, vice-president; W. J. Schroyer, vice-president, and C. R. Thomas, as secretary and treasurer, has been incorporated under the laws of Ohio and will have headquarters at 817 Dixie Terminal Building, Cincinnati.

The following companies have been chartered: **The Slater Coal & Supply Co.,** Lorain; capital $50,000; George L. Slater, S. S. McFadden, F. J. McFadden, D. A. Cook and Mayme J. Ambrozio. **The American Export & Inland Coal Co.,** Cincinnati; capital $100,000; E. F. Heasley, Stuart R. Ducker, M. Wellman, R. Johnson and Arthur W. Gordon. **The Merrimac Fuel Co.,** Cincinnati; capital $50,000; W. J. Quinn, H. E. Joseph, Ray E. Manley, Mary Barrett and Fanny Sachs. **Sanders Run Coal Co.,** Pittsburgh, Pa.; capital $10,000; incorporators, J. W. Plitcher, E. Glick, Charles Briskin and Philip Pearlman, all of Pittsburgh.

The so-called illegal coal contracts which were entered into by Edward J. Shattuck, purchasing agent for a time under the administration of Governor Harry L. Davis, were called to mind recently when the **Ohio Legislature was asked to include $80,000 in the general appropriation bill to pay for coal** delivered to various state departments and institutions before the contracts were declared illegal. The recommendation for payment was made by the Sundry Claims Board. The Finance Committees of the Ohio Legislature will now take up the question if payment is to be included in the general appropriation measure.

OKLAHOMA

The Henryetta Chamber of Commerce is sending out hundreds of invitations to coal dealers in Oklahoma and Texas, inviting them to hold their annual March convention in Henryetta in connection with the third annual state coal exposition and King Koal Karnival.

PENNSYLVANIA

Shipments of coal are continuing to run considerably above past records for this time of the year, according to statements made by various railroads. The Delaware, Lackawanna & Western, which with the Philadelphia & Reading and the Lehigh Valley is one of the most important coal-carrying systems, reported that **in January the road handled 224,000 cars more coal than in January, 1922,** and 245,000 more than last December. The road has caught up with production and is able to make shipments as rapidly as the mines can produce the coal.

A conference was held recently at the offices of the Department of Mines at which Joseph J. Walsh, chief of the department, and Frank Hall, deputy, discussed with E. A. Holbrook, dean of the School of Mines, Pennsylvania State College, and J. W. Paul, Federal Bureau of Mines, methods of bringing the work of the state department into closer harmony with the latter organizations.

A resolution recommending to Governor Pinchot the advisability of the **creation of a permanent body that would have general power to supervise the distribution of coal** within the state was introduced on Feb. 27 in the House of Representatives at Harrisburg by Representative Richard D. Burns, Philadelphia. Under the rules it was laid over for printing before action was taken.

Companies throughout the state employing coal and iron police appointed by the Governor have been requested in a letter sent to them by Governor Pinchot to furnish detailed information regarding the men in their employ. Accompanying the letters were application forms designed to show the qualifications and previous record of men seeking appointment. The Governor's action grew out of his recent announcement that commissions to coal and iron police would not be issued indiscriminately.

Employees of the H. C. Frick Coke Co. and other subsidiaries of the United States Steel Corporation in the Connellsville region who are beneficiaries of the United States Steel and Carnegie Pension Fund received a total of $108,988.89, or almost 9 per cent of the grand total of $1,266,661.74, disbursed by this agency during 1922.

River dredgers of anthracite coal, who have been paying their state tax under protest and been considering a court contest to avoid payment, are almost universally **making returns to the state on the basis of 30c. a ton** on all coal salvaged. This cost on the coal wharves is considered entirely too low by Samuel S. Lewis, Auditor General, who probably will take prompt action. Coal dredging is carried on in only half a dozen counties, but from all of these come the uniform price. River coal is selling at $1.25 a ton and higher and the 30c. price as representing the cost is believed to be too low.

The Fowler bill to repeal the anthracite coal tax law of 1921 was reported out of committee in the House of Representatives at Harrisburg on Feb. 27 with an affirmative recommendation. A determined effort to have the tax law repealed is said to be under way. It is probable, however, that if the bill is to pass it will provide that the law remain on the statute books until Jan. 1, 1925. This amendment is expected soon. The bill passed the House Feb. 28 on first reading. When read by its title the repealer was passed quickly in its first stage toward becoming a law. Whatever fight is contemplated against the repealer will come on the second and third readings, but supporters of the measure assert that they will pass it despite the opposition. The present tax added approximately 12c. to the cost of a ton of coal.

Sealed proposals will be received at the U. S. Engineer's office, Philadelphia, until noon, March 22, and then opened, for approximately **15,000 tons of semi-bitumi-**

nous coal for use on the floating plant in the Philadelphia engineer district during the period April 1, 1923, March 31, 1924.

Gas flames raging for several minutes around a group of miners who were drilling a rock hole at the Kaska William colliery, near Pottsville, Feb. 21, resulted in **the death of four miners** and one is in a critical condition. The explosion was not a violent one and but little damage was done the interior of the mine. The dead are Victor Lessau and Michael Broatus, of New Philadelphia; Martin Collier, of Tuscarora, and Anthony Wybokis, of Port Carbon. Anthony Blazner, Edward Sedar and John Triel, of New Philadelphia, were burned and indications were that Blazner will die.

A strike of four thousand miners employed at Nanticoke and Glen Lyon by the Susquehanna Collieries Co., **was settled Feb. 22**, when the men went back to work. Despite the holiday, each of the collieries that had been tied up for a week had a normal force of men. The strike started Feb. 16.

Barnum breaker, at Avoca, one of the oldest operations of the Pennsylvania Coal Co., **was abandoned** Feb. 28. Suspension is due to the completion of a tunnel which makes it possible for the coal to be sent to No. 9 breaker, at Hughestown. The tunnel was put through by Eugene Sullivan, an Avoca rock contractor. An appreciable saving in cost of operation will be effected by the new arrangement. Within the next few months the mines of the Barnum colliery will be electrified.

Dr. Royal A. Meeker was appointed State Commissioner of labor and industry by Governor Pinchot on Feb. 26. Dr. Meeker has been chief of the scientific division, international labor office of the League of Nations, since August 1, 1920. He succeeds Dr. Clifford B. Connelley. The Senate has confirmed the appointment of Dr. Meeker.

UTAH

The State Securities' Commission has granted the **Pahvant Coal Co. permission to sell $600,000 worth of bonds**, proceeds to be used in developing coal lands in Carbon County, where the company owns 640 acres. C. A. Quigley, formerly well known in the automobile business, is president of the company, and W. N. Wetzell is to be the manager. The company is incorporated for $2,000,000. It is planned to have this property producing next winter.

James C. Davis, as **Director of Railroads, has filed suits** against four prominent local coal operating companies **to recover on freight charges alleged to be due from Dec. 1, 1918, to March 1, 1920**. The Spring Canyon Co. is sued for $1,359.09 said to be due for transporting 182 cars of coal from their mines at Storrs. The Independent Coal & Coke Co. is sued for $2,015.71 for 242 cars between the same dates. The Carbon Fuel Co. is sued for $336.81, and the Standard for $542.30. The plaintiff claims the money is due as additional charges.

Governor Charles R. Mabey has signed the bill relating to certification for mine bosses which required that none but American citizens should be permitted to act in that capacity, except in the case of persons who have applied for citizenship.

VIRGINIA

Directors of the Chesapeake & Ohio and other Van Sweringen lines, on a tour of inspection of their lines, stated that a **$3,000,000 coal pier for Newport News** would be one of the principal items in a program for expending $8,000,000 on expansion of facilities. The plans for this pier, it is understood, have already been drawn. It also is planned to order about 2,500 new freight cars, rebuild about 3,000 freight cars and order 19 new locomotives.

At the regular meeting of the stockholders of the **Empire Anthracite Co.**, at Pulaski, March 14, all stockholders will go on record as for or against the **proposition to sell the entire holdings.**

WEST VIRGINIA

Collection of the "check-off" is forbidden under the terms of Senate Bill 263, introduced in the West Virginia Legislature by Senator McClaren of McDowell, upon request. This measure provides that no persons, firm or corporation in West Virginia shall hereafter enter into any contract for the collection of or collect any moneys commonly known as the "check-off," due to employees, from employers, over their payrolls for any purpose whatsoever except fees for medical attention, rent, etc. Violation of the provisions mentioned is made a misdemeanor.

The Consolidation Coal Products Co., in which New York people are interested, will erect in Fairmont a small byproduct plant in which coke, gas and other coal byproducts will be manufactured. Machinery is ready to be installed as soon as the building is completed. There will be the usual retort for the treatment of coal, with the necessary mechanical and electrical driving machinery. The tar equipment will consist of two steel storage tanks of a capacity of 20,000 gallons each, one tar decanter with a capacity of 1,500 gallons and one tar pump tank with a capacity of 300 gallons.

Organization of the **Hancock Coal & Clay Co.** with a capital stock of $50,000, presages the development of coal and clay deposits in Hancock County. Headquarters of the company are to be at Weirton. The following are interested in the new company: M. George, George Bollers, James Potts, O. M. Hoffman and Louis Zokos, all of Weirton.

An agreement has been reached between some northern West Virginia coal operators and officials of District No. 17, United Mine Workers of America, on **a new wage scale**. The agreement negotiated represents an agreement among individual operators. There are a number of coal companies though not a party to any agreement, as for instance some of the companies operating in the Elkins region and also in other parts of the district. The new agreement is similar to the agreement which has been in effect since the settlement of the strike last summer, and is for another year. There are a few minor changes relating to working conditions. The minimum rate fixed is 60.7c. per ton for miners producing high coal in machine mines. Where working conditions are not so satisfactory the rate is as high as $1.00 per ton. Under the scale agreed upon day men will receive from $6.55 to $8.10 a day.

Miners and others interested will be afforded a short course in coal mining between June 11 and July 21, according to an announcement by Prof. A. C. Callen, head of the department of coal mining of West Virginia University. It is estimated that between 150 and 200 men will attend the short course. The course is intended to assist mining men to obtain certificates of competency as mine foremen or firebosses and to give the man with a certificate even a more thorough knowledge of coal mining.

The New River Co., the largest company operating in the New River field, has been successful in having set aside for sixty days the order of the Interstate Commerce Commission, recently made effective, limiting joint mines to a 100 per cent supply instead of a 150 per cent supply of cars. Suspension of the Interstate Commerce Commission regulations was covered in an order entered by the U. S. District Court for the Southern District of West Virginia early in February. Circuit Judge Edmund Waddell, Jr., and District Judge George W. McClintic signed the suspension order. Circuit Judge Charles A. Wood dissented.

The Supreme Court of West Virginia has been called upon to determine the ownership of coal rights in a tract of 110 acres of land in Monongalia County from which gas and oil is being taken, in the case of Blake Lemley Ramage against the South Penn Oil Co. The plaintiff contends that the right to mine coal never passed and that he owns the coal deposits. The lower court decreed the title to the coal land to be in the plaintiff.

The sale of an additional block of stock of the **Coal River Collieries Co.** will be used in order to permit **additional development of the property** of the company. The capital stock has been increased, according to an announcement made by Harry Leaberry, president, from $2,000,000 to $2,500,000. The stock is owned entirely by the members of the Brotherhood of Locomotive Engineers. The company owns a block of 10,000 acres of coal land on Coal River, where extensive improvements are being made and where the construction of a large steel twin tipple is now nearing completion.

Machinery rather than men will be relied upon to a great extent in a mine which is being opened by Paul Hardy and associates in the high-volatile territory served by the Norfolk & Western. The mine is expected ultimately to produce 2,500 tons of coal a day, which will be cut, loaded, hauled and dumped by machinery. Not more than 50 men at the most will be employed. As this may be the means of solving labor problems, coal men in the southern part of the state are watching the experiment with interest.

The Mellon interests of Pittsburgh **have acquired control of 27,000 acres of coal land in Boone County** not far from Madison on the Pond fork of Coal River and on the Coal River division of the Chesapeake & Ohio Ry. It was purchased from the Wharton estate, of Philadelphia, for a consideration said to approximate $2,700,000. Coal produced at the mines now owned by the Mellons will be used largely for by-product purposes.

Stockholders of the **Greenbrier Smokeless Coal Co.** at a meeting held in Lewisburg, Greenbrier County, late in February, elected the following directors: R. M. Bell, Mason Bell and W. E. Nelson, of Lewisburg; W. B. Hines, of White Sulphur; Edward Graff, of Macdonald, and A. Erskine Miller, of Staunton. A report made by general manager H. H. Blackburn disclosed rapid development of the property of the company in the new Greenbrier smokeless field, the mines of this company being among the first opened in the field.

House Bill No., 476, introduced in the House of Delegates by Representative Strother, of Welch, **proposes that the mine inspection year be made concurrent with the calendar year.** It would change the present law so that the chief of the department of mines would make his annual report to the Governor for the year ending Dec. 31, instead of June 30, and to file it not later than June 30. Each district mine inspector would be required to make his annual report in like manner. Another amendment proposed in the Strother bill would require that the operator or agent of every coal mine must mail or deliver to the chief of the department of mines in January instead of July a report for the preceding twelve months ending with December instead of June.

Another attempt will be made to organize the non-union coal fields of West Virginia, according to word reaching operators in Charleston. Percy Tetlow, mine union organizer, and a corps of assistants, are expected to enter the fields within the next thirty days. A fund of $1,500,000 is declared to have been collected for the purpose during the last few months when each union miner was assessed $2 a month in addition to regular union dues. It cost the miners $2,000,000 to try to organize West Virginia in its last attempt, it is said.

WISCONSIN

A bill which aims to keep water out of coke sold in Wisconsin has been introduced in the Legislature. It is asserted that coke has been sold 30 per cent of the weight of which represented water. A tolerance of 10 per cent moisture is to be allowed for coke. Any excess over that amount will have to be deducted if the bill becomes a law.

WYOMING

In January the **Owl Creek Coal Co.**, at Gebo, **mined over 2,000 tons per day** worked, according to **J. C. Rae**, general superintendent. Mr. Rae attended the meetings of the Rocky Mountain Coal Mining Institute in Denver, Colo. Feb. 26, 27, and 28. **Albert Griffin**, of the Owl Creek organization, also visited in Denver.

CANADA

COAL OUTPUT OF BRITISH COLUMBIA, JANUARY, 1923.

Mine	Tons
Vancouver Island District	
Western Fuel Corporation of Canada, Nanaimo	60,540
Canadian Collieries (D) Ltd., Cumberland	23,180
Canadian Collieries (D) Ltd., Extension	17,744
Canadian Collieries (D) Ltd., South Wellington	10,268
Granby Consolidated M. S. & P. Co., Cassidy	24,615
Nanoose Wellington Collieries, Lantzville Mine	10,438
Old Wellington Colliery	1,002
Total	147,787
Nicola-Princeton District	
Middlesboro Collieries, Middlesboro	7,236
Fleming Coal Co., Ltd., Merritt	1,984
Coalmont Collieries, Coalmont	14,919
Princeton Coal & Land Co., Princeton	2,218
Total	26,357
Crow's Nest Pass District	
Crow's Nest Pass Coal Co., Coal Creek	58,842
Crow's Nest Pass Coal Co., Michel	32,492
Corbin Coal & Coke Co., Corbin	5,587.32

Grand Total, January	271,065.32

Initial steps were taken to form a **Canadian industrial research organization to solve the Canadian fuel problem** at a recent conference in Ottawa of representatives of the universities of the Dominion, of the scientific branches of the government and of the Canadian Manufacturers' Association.

The summary discharge of Sid McNeill, which resulted in a strike of 2,500 employees of the British Empire Steel Corporation, **was upheld** Feb. 21 at a hearing, agreed upon by strikers and company officials, in a strike settlement. The workers have returned to their posts and are bound by agreement to abide by the decision regarding McNeill.

William Sloan, Minister of mines, in an address at Nanaimo on Feb. 23 emphasized that the importation of **foreign fuel oil was undermining the coal-mining industry on Vancouver Island** and advocated an increased importation duty on fuel oil. Mr. Sloan stated that in 1910 the coal output of the province was 2,800,000 tons, compared with 2,595,000 tons in 1920 and 2,483,995 tons in 1921. In 1910 importation of fuel oil began to assume considerable proportions, and at the present time is replacing 90,000 tons of coal per month, or a volume equal to approximately three-quarters of the present monthly output. Mr. Sloan will leave soon for Ottawa, where he will bring to the notice of the Dominion Government the need for increasing the tariff on fuel oil, so far as British Columbia is concerned, at any rate.

The Herewood Mine, Western Fuel Corporation of Canada, Nanaimo, B. C., **has been closed down** and, it is understood, **is to be completely abandoned.** This property is situated about three miles from the City of Nanaimo. It was opened some 40 years ago and its initial operation was unique by reason of the fact that transportation was effected by means of an aerial tramway from the mine to Nanaimo Harbor. Over a considerable period it was shut down and was developed a second time by the New Vancouver Coal Co., which since has passed out of existence. Once more its workings were deserted, not becoming active again until 1916, when the Western Fuel Corp. took hold and so pushed work that during the war the Herewood became a considerable producer. It was at this time that it reached its peak in point of output, an average of 1,000 tons a day being mined and brought to the surface. In recent months the production has been steadily declining until finally it ran to only a few hundred tons a day.

Traffic News

Electrification of 80 miles of the Virginian Ry. through the coal fields in Virginia and West Virginia has been announced. The new process will extend from Pulaski, Va., to Elmo, W. Va., according to announcement. This will greatly facilitate movement of coal to Tidewater, where the Virginian's new pier, costing over $3,000,000, is now being built.

On account of accumulation an **embargo** has been placed by the **New York Central R.R.** against all shipments of coke consigned, reconsigned or intended for Hart & Crouse, Utica, N. Y.

Embargo 298, placed Feb. 21 by the **New York Central R.R.** against all freight for delivery to the Fonda, Johnstown & Gloversville Ry., has been **modified** to include in the exceptions bituminous coal consigned to the F. J. & G. R.R. for its own supply use.

Embargo 292, placed by the **New York Central R.R.** against all shipments of coal consigned to or intended for the Buffalo General Electric Co., Harriet, N. Y., has been **entirely cancelled.**

Embargo 420-D, placed by the New York Dock Ry. (Fulton, Baltic and Atlantic Terminals) Brooklyn, N. Y., against shipments of coal and coke consigned or intended for delivery to Patrick Reilly, D. Reilly and E. A. Tutein Co. is **entirely cancelled.**

Domestic coal handlers, steamboat concerns and others interested are preparing to make a stiff fight against the proposal of the Norfolk & Western Ry. and the Virginian Ry. **to discontinue the flat rate on coal for customers who require barging** to their plants. This is a practice which has operated at Norfolk for twenty-five years, and the railroads propose to discontinue it as of April 1. Under the proposed new arrangement the rate on coal delivered to any waterfront plant not connected by rail would be the same as the rate to any point in the harbor inside the Capes. The Chamber of Commerce and other commercial bodies are opposing the proposed revision of rates.

Amendment No. 1 to Service Order No. 38 was issued by the Interstate Commerce Commission Feb. 26. By its provisions Service Order No. 38 is vacated and set aside effective at midnight Feb. 26.

In a complaint filed with the Interstate Commerce Commission Jan. 31 by the **Colorado Fuel & Iron Co. against James C. Davis,** Director General of Railroads, and his successors, as agent, and the **Colorado & Wyoming Ry.,** the complainant asks in reparation for unlawful charges for freight on an electric locomotive the sum of $232.02 with interest.

Reports of several of the more prominent railroads show that during January the **Philadelphia & Reading Ry.** made an increase in net operating income for January, 1923, of $1,880,258 over the same month of the preceding year. **The Lehigh Valley** showed a deficit in January of $929,033, against a credit of $350,514 in January, 1922. The disappointing showing made by this road was due to maintenance of equipment expenditures $887,953 higher in January, 1923, than the year previous and transportation expenses $362,640 higher. **The New York, New Haven & Hartford** reported a net operating deficit of $780,587 in January, against net income of $892,565 in January, 1922. The January gross income amounted to $9,911,556, against $8,724,503. **The New York, Ontario & Western** reported a net operating deficit of $208,615, against a deficit of only $92,418 in the same month of 1922. **The Atchison, Topeka & Santa Fe** had January gross income of $19,217,191, against $14,606,364 the same month of the preceding year, and net income of $4,328,238, against $561,102 in January, 1922. **The Chicago Milwaukee & St. Paul** showed a substantial increase in both gross and net operating revenue for January. Gross revenue was $14,470,239, a gain of $3,597,992 over the same month in 1922, and net operating income, totaled $1,824,419 against a deficit of $466,786 in January, 1922. **The Central Railroad of New Jersey** reported total operating revenue in January of $4,364,572 against $5,969,907 in January of the preceding year, and net operating income of $117,139 against $205,076. **The Missouri, Kansas & Texas** reported net operating income of $519,321 in January, an increase of $255,527 over the corresponding month of the preceding year. **The Illinois Central** report for January showed a gross of $16,595,121, against $12,608,683 in 1922 and net operating income of $2,879,533 against $1,588,585. **The Erie** had a net operating income of $321,521, against $199,303 in 1922 and total revenue was $9,652,325 against $7,177,250. **The Southern Ry.** showed excellent January earnings. Operating revenue was $12,052,413 against $9,217,531 in the same month of the preceding year and net income after taxes, etc., was $2,196,430, compared with $736,196 the same month a year ago. **The Delaware & Hudson** reported a deficit of $400,000.

Senator Brookhart, of Iowa, head of a committee of the new progressive bloc charged with transportation legislation, in introducing a bill on Feb. 24 to repeal vital sections of the Esch-Cummins transportation act, **urged an extra session of the next Congress to consider railroad legislation.** Abolition of the Railroad Labor Board, transfer of its functions within six months to the Federal Board of Mediation, repeal of the 6 per cent. income guarantee of the law and drastic changes in railroad valuation are provided for in Senator Brookhart's bill. He said the measure if passed would "take seven billion dollars of water out of the valuation" of railroads. "The bill also stops the capitalization of unearned increment in property value," said Senator Brookhart, "and defines the adequate return so it will not exceed the interest rate on the bonded portion of the capital." Interlocking directorates and Interstate Commerce Commission jurisdiction over intrastate rates also are prohibited by the terms of the bill, Senator Brookhart promised to introduce another bill later "to stop excessive profiteering by subsidiary corporations."

The Interstate Commerce Commission has approved the application of the **Louisville & Nashville R.R. to issue $45,000,000 additional capital stock to be distributed as a stock dividend.** Approval was given on condition that certain holdings of stock of affiliated companies of the road shall not be disposed of without first procuring permission from the Interstate Commerce Commission and that no expenditures made prior to Oct. 1, 1922, shall be capitalized by issue of bonds or other securities to reimburse the treasury of the Louisville & Nashville. The increase is equal to 62.5 per cent. of the present outstanding stock of $72,000,000.

For the purpose of developing an area of virgin timber and New River type of coal, the **Chesapeake & Ohio** asked permission of the Interstate Commerce Commission March 2 **to build an extension of its Gauley branch** 10.6 miles beyond Bryce, W. Va. The territory to be served, the applicant said, was now inaccessible to railroad, notwithstanding the good timber and the high quality of coal.

Hearing before Harris Fleming, examiner for the Interstate Commerce Commission, was held in Newport News last week in an effort to arrive at some **adjustment of the Newport News freight rate on anthracite.** This rate is $4.30, gross, while the rate to Norfolk and Richmond is $3.40 gross. The Chesapeake & Ohio Ry. agreed to give Newport News the lower rate, but the Pennsylvania proposed a rate of $3.91, which was not agreeable to the Newport News dealers.

The Boston & Maine R.R. has put into effect a new schedule of discharging rates on coal and coke at Boston and at Salem, Mass. The increase was made in the face of strong opposition at a recent hearing before the wharf commission. New discharging rate on coal per gross ton, single deck vessels, is 35c.; other type vessels 45c. On coke the rate net, single deck vessels is 70c. a ton and on other type vessels 90c. Weighing charges on coal are placed at 4c. a gross ton with a minimum charge a car of $1.35; on coke 6c. a net ton with minimum of $1.35 a car. For services performed on holidays the rates are 50 per cent higher.

Obituary

Paul C. Voss, former salesman for the Harvey-Jellico Coal Co., Louisville, died at his home on Greenwood Avenue on Feb. 17 of a complication of diseases, after an illness of a year. He is survived by his parents, a brother and one sister.

E. H. Irwin, 63, sales manager of the Harrisburg Colliery Co., died at his home in Chicago, Ill., Feb. 20, from pneumonia. Mr. Irwin, who was well known in the midwestern coal trade, was born in Glendale, Ky. He began his career in the coal industry by long service for Hull & Co. in Louisville, Ky., New York and Chicago. Later he joined the O'Gara Coal Co., which operates in southern Illinois. He left the sales managership of that company to join the Harrisburg Colliery Co. in January, 1922. Funeral services were held in Chicago, Feb. 22 and the body was taken to Elizabethtown, Ky., for burial the following day. He is survived by his widow, one son and two brothers, W. B. Irwin, Riverside, Cal., and Judge J. L. Irwin, county judge of Hardin County, Kentucky.

Coming Meetings

International Chamber of Commerce will hold its second general meeting in Rome, Italy, March 19-26.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, **E. Marburg.** Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, **F. O.** Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., Dec. 11-14. Executive secretary, **S. N.** Clarkson, Cleveland, Ohio.

Indiana Bituminous Coal Operators' Association will hold its annual meeting March 14 at Terre Haute, Ind. Secretary, **P. H.** Penna, Terre Haute, Ind.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, **O. K. Davis,** 1 Hanover Square, New York City.

The Gas and Fuel Section of the American Chemical Society is arranging a second sectional meeting at the New Haven meeting of the American Chemical Society during the first week in April. The section program will consist of papers on gas and fuel chemistry and a symposium on motor fuels, held jointly with the petroleum division.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, THURSDAY, MARCH 15, 1923 Number 11

Massachusetts Lists the Gougers!

THE Legislature of Massachusetts has indulged in anthracite publicity. In an official document traders in anthracite from so-called "independent" sources are named for public censure, the hairline being drawn between "company" coal at $9.50 f.o.b. mines and "premium" product at prices above that magic figure.

With due allowance for politics and the public appetite for coal scandal the data assembled for the Legislature by the Massachusetts Commission on the Necessaries of Life may prove of value, although exception can be taken to some of the conclusions reached. It should be useful to have consumers told officially that from the resumption of mining to Jan. 31, 1923, the ratio of "independent" receipts in Massachusetts to those of "company" coal was but 14 to 86, taking $1.25 over the "company" price as the dividing point. Further, of the eighty-one "jobbers, wholesalers, brokers and dealers" listed as exacting more than $9.50 but two are reported selling in excess of 20,000 tons, and only four as selling more than 10,000 tons. To state it differently, but thirty-four have sold each more than 1,000 tons, and of these, eighteen are parties outside of Massachusetts.

For the good of the industry and in the interest of fair dealing the Legislature ought now to publish the names and tonnages of wholesalers who ship "company" coal. Neither politicians nor the press would be interested and doubtless the items would lack news value, but the complete figures would be enlightening. If lawmakers are to delve into the anthracite business let them favor the "fair-price" wholesalers with equal publicity, that the public may get a more accurate impression of a distribution that 86 per cent merits approbation.

It is reasoned, according to the Massachusetts commission, that "under the prevailing system of the Pennsylvania Fuel Commission for distributing anthracite this large amount of high-price coal has reduced the allotment to Massachusetts of a larger amount of lower-priced company coal. There is no apparent shortage of this high-priced coal." The trade may well question the implication of this statement. "Undoubtedly," naïvely continues the report, "our retail dealers intended by purchasing this coal to increase the amount of coal received by their communities. Their action, however, has apparently resulted only in raising the price of speculative coal and thus the price our householders must pay." This is a philosophy nothing short of artless. No reference to a strike that lasted from April 1 to Sept. 18!

We have no wish to condone speculative premiums on necessaries of life. Undoubtedly there are serious abuses, but by the Massachusetts list the tonnage shipped into that state at prices averaging more than $10.75 was relatively small. Vigilant as proved the war-time Federal Fuel Administration we have our doubts whether even the most meticulous policing would even then have prevented similar abuses in like proportion. It rather seems to us that time is wasted in recriminations over a situation the direct result of five months and a half of idleness in the anthracite region, and not yet a constructive suggestion!

"The Worst Conducted Industry"

SOME time ago Herbert Hoover remarked that the coal industry was the worst functioning of industries. Recently, we believe, he has been weakening in that notion, which was entirely unjustified, as indeed everyone knows. It is a seasonal industry, but there are many others more seasonal and many more that possess that quality in no less a degree.

Now comes John Hays Hammond with the statement that "This industry is the worst conducted, from an engineering point of view, that I have ever seen." The charge is a serious one to make against coal-mine executives, the more serious indeed that it applies to nearly all the more important leaders in industry. This sweeping charge includes Gary, Schwab, Rockefeller and Ford, all of whom are at the head of organizations owning and operating coal mines. It includes many of the heads of the great metal-mining companies, those who rule the destinies of the Phelps Dodge Corporation, the American Smelting & Refining Co., the United States Smelting, Refining & Mining Co., the Chino Copper Co., the Ray Consolidated Copper Co. and the Anaconda Copper Mining Co.

The railroads, the electric-light and power companies, the big byproduct and gas companies, the oil companies, the steel corporations other than those referred to, which are dominated by Gary, Rockefeller and Schwab, also own coal mines. Thus he has denounced the leaders of almost all industry except perhaps his own—that of mining gold. As one scans the situation one would be inclined to believe that the coal mines must be unusually well circumstanced in the matter of executive and engineering talent, because they have had the advantage of sidelights contributed by men from all the industries, for surely each man must contribute something from his especial environment.

No one knows just to what Mr. Hammond refers in his arraignment of the coal industry. That is locked in his bosom. Perhaps it is the eight-hour as against the sixteen- or twenty-four hour day. He has been prone to say that coal mines should operate without surcease every hour of the week. Most of us rejoice that the mines work only eight to ten hours. The world is the better that night is not turned into day. Many industries have seen fit, we are glad to say, to keep largely or wholly to the shorter working period, and in view of the repairs to be made, the roads to be graded and the need for the continuous development

of headings to maintain an eight-hour day, perhaps this method of operation is not such an unfortunate and unprofitable arrangement.

D. C. Ashmead has shown that in the anthracite region the shorter day is preferable economically to the double or triple shift. Coal mines, it is true, work more hours in Europe, but see how much lower is their tonnage per mine and per man. Furthermore, almost all our coal cutting and much of our pumping is done at night, thus lowering the peakload and saving machinery.

If Mr. Hammond refers to the payment by the ton and the fact that with such piece work the interest of the operator and the miner is not so co-ordinated that the former can afford to expend money to assist the latter in producing a large tonnage, there is truth in the statement, though most operators will reply with at least some degree of truth that day work at the face would remove any incentive from the miner to do a good day's work.

Everyone likes to run the mines and the railroads. Any day laborer—a dumper at the mines or a brakeman at the wheel—thinks he could do better than Clingerman or Loree. The average commuter and traveling salesman believes he could handle either mines or railroads better than any man brought up in the business. It is a national failing to declare that we could do another man's job better than he could, but when we try to undertake the work it soon becomes evident that after all the men we criticize know a little at least that we did not know and that the best work in mining or railroading is being done by men versed in the mining or railroading art.

Stream Pollution

MR. CRICHTON'S gloomy prognostications as to progressive stream pollution contained on pages 447-451 of this issue carry the conviction of the writer home to all who read them. Nevertheless some features in future operation promise relief from a difficult situation. One of these favorable features is that most of the workings hitherto have been made near the outcrop, and as mining progresses this shallow coal is approaching exhaustion.

After awhile the coal will be nearly all under heavier cover and the crevices to the surface will be smaller and will close more completely so as to shut off surface waters almost entirely. It is in shallow mines that complete collapse takes place and not in those that are deep. Many of the mines of the future will receive only, or almost only, ground waters; especially will that be true when the surface has completely subsided. On the other hand it well may be that after a few years we may undertake to strip coal along the crops, thus adding to the area of the shallow workings.

As a further reason for hoping that Mr. Crichton's prophecy will be fulfilled only in part is the fact that the mining of the thinner measures, now beginning to look practicable for working, does not produce as much surface disturbance as the mining of those that are thicker. It must be remembered, however, that the thinner they are the more rapid must be the excavation and that there are still not a few thin or dirty beds above those hitherto worked and these will be near the outcrop and have shallow cover. As time goes on these beds tend to be developed, and when they are, they will freely admit surface water and assist materially in aiding that water to reach lower levels.

Evidence also goes to show that not only the seam worked but seams above, still undeveloped, supply sulphurous material to the waters that pass through them and that what is leached from them now will not be present to be leached later. Consequently these upper seams will be less harmful when worked than those we are now working. As against this it must be remembered that the neutralizing bodies also are being removed, and this will tend in a degree to act as a balance to the loss of acidifying tendencies.

Mr. Crichton points out also that after many years old mines tend to give water that is not acidified. He also declares that the area mined is not a complete index of the water received by the underground workings, for, as he well says, the mines are fed by the rainfall of unmined areas as well as of those already mined. In consequence of this second fact the increase in the area draining into mines, new and old, will hereafter be less than in exact proportion to the areas extracted. Unfortunately we lack data of all kinds, especially as to the water entering mines of greater depth where one or more seams are worked, as to the acidity of the waters leaving such workings, as to the nature of water from strippings and as to the length of time after which a mine will cease to acidify the waters it receives.

It must be remembered that the acidity per ton of coal mined is not the main interest, but rather the number of grains of sulphuric acid per inch-acre of rainfall, the waters from which pass over the mine workings. If the water from the shaft mine is strongly acid it may nevertheless be in such small quantity that it will have less evil effect on the stream which it enters than the clearer water from the drift mine. The tendency with deep measures may well be to produce a highly acidulous water, but such a small volume of effluent as to overbalance the effect of greater acidity.

Some of our institutions are looking for subjects for study. They might do worse than consider this foundling that so far has had few who would give it parental attention. A study advantageously might be made of a deep shaft operation and of a shallow drift mine to determine which will result in the greater total of acidity, bearing in mind, however, in making a selection, how greatly the presence of limestones may modify that quality.

Two mines in the anthracite region side by side are of equal depth but have totally different waters. One, Pine Hill, has water much more acid than usual. The other, the Lytle Colliery, was some ten years ago using the water from the mine for boiler fuel and did not find it necessary to neutralize the acid. This shows the necessity for caution in accepting comparisons as typical.

The subject is a big one and, as Herbert Hoover says, we should know what we are doing before we legislate. Furthermore, we must remember that all those who are declaiming against this stream pollution are profiting indirectly by the operation of the mines by which the pollution is caused. They can ill afford to make mining unprofitable.

WORK AT WORK.—Secretary Work has ordered that his office door be kept open. The public will thus have a chance to see Work work if it is possible for Work to work while office seekers are trying to work Work.—*Boston Transcript.*

Mining Machines Save Spadra, Arkansas, Field from Extinction After Long Fight with Union

For Years Solid Shooting Made High Percentage of Screenings —Small Quantity of Lump Cut Working Time by Limiting Market—Machine Scale with 7-In. Differential Now Made

By H. Denman
Clarksville, Ark.

IN THIS age of machine mining it probably will seem strange to most *Coal Age* readers to hear of a field where conditions were favorable to the use of machines yet where a mighty struggle had to be waged within recent years to get them introduced. This struggle against prejudice was so severe in the Spadra field of Arkansas that the entire region was shut down for almost a year on account of it. Nearly four years of battle by the operators against the district and local organization of the United Mine Workers of America was necessary before a machine scale finally was provided. Local conferences and negotiations by the operators and the Southwestern Interstate Coal Operators' Association at Fort Smith, Ark., and at Kansas City, Mo., cost thousands of dollars and much time and effort. But the results may be worth the cost of the struggle.

The operators of the Spadra field appealed to the National Coal Commission appointed by President Wilson and to every official who they thought might help them get a scale, and finally, largely through the assistance of John P. White, representing John L. Lewis, president of the national organization, they were able late in the autumn of 1921 to secure a machine scale allowing them to install mining machines. Even then it would appear that a scale would not have been obtained if the production of an excessive quantity of slack coal under the solid-shooting system of mining and a strictly limited market for low-volatile slack had not compelled the Spadra operators to close down their mines from the autumn of 1920 until the autumn of the year following, when the scale was made. This long spell of idleness, due to market conditions, was a stronger argument for the machines than any talk the operators could make. The percentage of slack had reached startling proportions, so large, indeed, that it reduced the available lump for the domestic market to a seriously low point.

In order to make clear how such a situation could exist, it will be necessary to give a short description of the Spadra coal, the coal field and its markets. Both the district and the coal itself in many ways are unique.

The Spadra district is in Johnson County, Ark. It is only a part of a larger field extending from a point about 75 miles east of the western boundary of Arkansas across the western line of that state and for a distance of about 100 miles into Oklahoma, but the coal

Note—The headpiece of this article shows the breaker and headframe at No. 2 mine of the Fernwood Mining Co., near Clarksville, Ark.

MACHINE MINING MUCH INCREASED LUMP PERCENTAGE

Until recently in the little Spadra field of Arkansas solid shooting in hard coal blew a large proportion of the coal to slack, for which there was a poor market. Today the proportions are much more wholesome, increasing the volume of good marketable lump, thanks to special cutting machines which are a cross between shortwall and longwall. This shows a shot of machine-mined coal, a large percentage of which will afford domestic sizes.

in the Spadra district differs in character from that in the rest of the field. Generally speaking, the coal in the western end of the larger coal area is highly bituminous and high in volatile matter, whereas that in the eastern end is high in fixed carbon and closely approximates anthracite. The Spadra field lies in a basin located near the eastern end of the general Arkansas-Oklahoma coal field and is high enough in fixed carbon for the coal to be classed as semi-anthracite though it is prepared like the hard coals of Pennsylvania and marketed as Arkansas anthracite. Geologically, this coal is in the "Pennsylvanian" or Middle Carboniferous series, and the U. S. Geological Survey in commenting on the coal fields of the state remarks that "Coals of as good quality are not found elsewhere in the United States west of West Virginia."

The following is a typical analysis of Spadra coal sampled and analyzed by the U. S. Geological Survey:

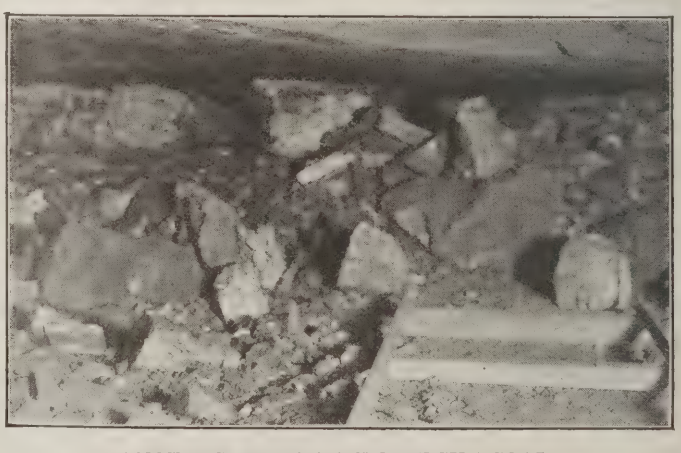
ANALYSIS OF SEMI-ANTHRACITE FROM SPADRA FIELD—AIR-DRIED SAMPLE

Constituents	Per Cent
Moisture	1.03
Volatile matter	10.53
Fixed carbon	80.06
Ash	8.38
	100.00
Sulphur	2.31

The Spadra basin is about 12 miles long in an easterly and westerly direction and 10 miles across from the north to the south outcrop. The coal seam is about 40 in. thick with a band of slate near the center varying from a mere streak to several inches in thickness, the entire bed becoming thicker as the band rock thickens.

The dips are not steep and usually do not exceed 2 or 3 deg. The roof is good, the floor hard, and the mines have little water and not much gas. All the mines of any importance are shafts varying in depth from sixty to three hundred and sixty feet. From this description anyone would say that the natural conditions were favorable for machine mining, and the market conditions even more strongly favor it.

I have already stated that this coal is marketed as Arkansas anthracite, and although the geologists might not so classify it it will uphold the reputation of anthracite and perform the same service as if the prefix "semi" were not written before the word "anthracite." In preparing it for market it is first broken down in breakers or crushers and then carefully screened into five, and sometimes six, sizes, the larger grades being hand picked with much care. The sizes made are grate, egg, No. 4, chestnut, buckwheat (sometimes) and slack. The coal, excepting the slack and buckwheat, are used exclusively for domestic purposes in base burners and furnaces, and the principal market for the coal is in the North and Northwest. The coal burns like Pennsylvania anthracite and just as satisfactorily, but it is not so hard and makes a little more slack and fine coal in transportation and handling. It is smokeless, burns with little flame and maintains a fire for a long time with a strong, steady heat.



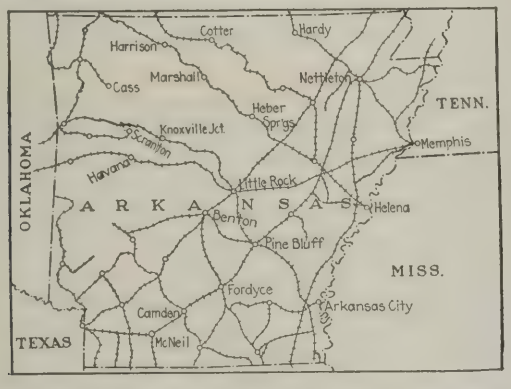
The slack, being low in volatile matter, non-coking and screened fine, though a high-grade fuel, is difficult to burn under the conditions existing at most of the steam plants in the Southwest. To get the most satisfactory results as a fuel it should be pulverized and blown into the furnace with a stream of air, the coal burning while in suspension. There are few of these plants, however, and they are expensive to install.

Zinc Smelteries Only Market for Slack

The consequence is that our only market for the slack and for most of the buckwheat is the zinc smelteries, where it is used as a flux in reducing certain grades of zinc ores. With this limited market for slack coal the demand for it is uncertain, depending on the condition of the zinc business. Since 1918 this business throughout the territory that Spadra supplies has not been active, and the demand for slack coal has been greatly restricted. This necessitated stocking coal every year, a portion or all of the slack mined during a part or all of the season being put into the storage pile when the demand for domestic grades of coal was active.

As the coal is used principally for domestic purposes the running time of the mines depends on the seasons, usually starting in the early summer and continuing till near the end of the year. If the mines cannot operate during that season they must lie idle until the one following.

In the past all the coal has been shot from the solid, making an excessive amount of fine coal and the sizes were so badly powder-shattered that they did not stand transporting and handling as coal of this character



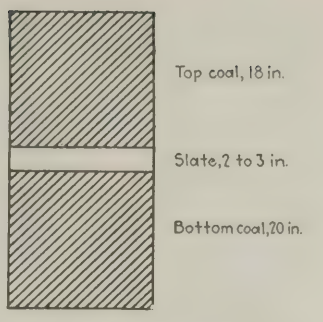
ANOTHER SHOT OF UNDERCUT COAL

As this coal was of a type not readily explosible as unfortunately is most coal in the Southwest, the demand that it be undercut before shooting was not on the grounds of greater safety but on the economic basis that without larger coal the Spadra field would be obliged to suspend operation.

should. As there is little danger that dust explosions will be caused by shots in this coal, charges that the shotfirer would not be permitted to shoot in any other coal bed were used in the Spadra mines to blast coal from the solid. All the coal close to the shots was ground to powder, and the slate band in the center of the bed was so badly shattered that it was almost physically impossible for the miner to separate it from the coal. Most of it, especially where the band was not thick, was loaded with the coal into the mine car.

It is needless to explain that this system of mining produced an excessive quantity of fine coal, for which there was little or no market for long periods at a time. As a consequence the price for the slack coal was low and that for the domestic sizes too high—several times that paid for slack. The operators tried stocking the slack, but such a large proportion of the output came under that head and under that of buckwheat that they found this a losing proposition and "quit it as a bad job."

Years ago this field paid its miners on a screen-coal basis, and this system produced a comparatively small



ARKANSAS AND ITS SEMI-ANTHRACITE FIELD

The coal area lies immediately north of Scranton, Ark., in an area so remote from the anthracite region of Pennsylvania that the demand for its product should be considerable.

proportion of fine coal, but through the efforts of the United Mine Workers the state Legislature passed a mine-run law, compelling all coal to be weighed before screening and paid for on a mine-run basis. This law was afterward repealed for Johnson County, but the operators were not able to get another scale for screen coal, so for years they had been obliged to see their coal blown to dust as a result of shooting the coal out of the solid.

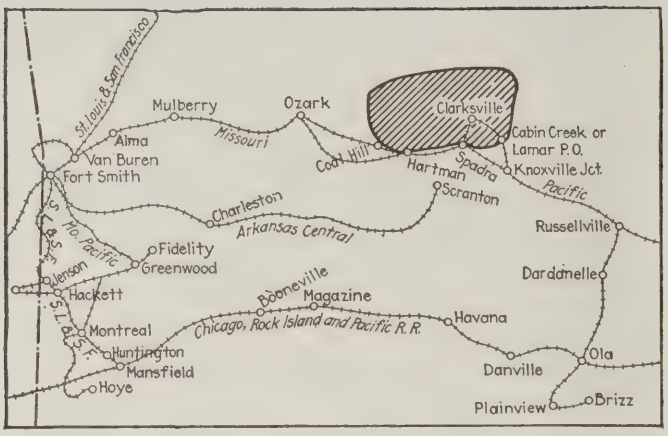
Some of the Spadra operators early realized the advantage to be derived from the use of mining machines but there were others that did not believe they could be used with success, so at first the operators were not unanimous in demanding the right to use machines.

In 1918 the Fernwood Mining Co. requested the union through the Southwestern Interstate Coal Operators' Association to provide with a machine scale for a new mine it was then opening. Some of the other operators joined in making this demand for the field. Several conferences were held from place to place without success. Finally, however, early in 1919 the chief commissioner of the Southwestern Interstate Coal Operators' Association and a number of Spadra operators met the district president of the United Mine Workers of America and other union officials and an agreement was made under which a mining machine was to be given a 30 days' trial in one of the mines with a view to determining the practicability of machine mining and the proper basis for the establishment of a machine scale. A standard electric shortwall undercutting machine was furnished by a manufacturer for trial purposes, and the Collier-Dunlap mine was chosen for the test run.

SPADRA SEAM

Two hard and thin seams of coal with a thick binder is the kind of bed to require heavy shooting unless the material is first cut by machine.

Before beginning the test and while it was being conducted there was a constant squabble over details, such as what men should do the work, whether they should be paid by the ton or on a day-wage basis and many other points of difference. Though the test was to be run 30 days, it did not actually run half that length of time owing to the many points of difference that arose. Finally by mutual agreement the test was ended. Though the days during which the machines were operated were comparatively few, many months were consumed in the "test."



It was of little value, however, for the purpose of making a machine scale, for which it was primarily intended, as the disposition of the local union officials and the men loading after the machines was to do as little as possible, with the hope that they might establish thereby a favorable loading rate. Before this test most of the miners and some of the operators thought the mining machine entirely impracticable for this field, but the actual operation of the coal cutter convinced all the operators and many of the miners that the coal could be undercut successfully by machines and that they thereby would reduce the percentage of fine coal and obtain a cleaner and firmer product. This test was conducted in the spring of 1919.

The next step was to get together with the union officials and make a scale for machine work. Then followed conference after conference, absolutely without results. After trying every means we knew or anyone could suggest, the operators nearly despaired of getting a scale. In the meantime the slack situation had grown worse and some of the operators wanted a screened-coal scale for pick mining or anything that would help to solve the slack problem. They were unable to obtain a reasonable pick scale; in fact the miners did not seem willing to make any change except one that would afford them not only the wage they were receiving but an assurance of an increase in earnings.

In 1920 the market for slack improved and the Spadra mines were able to operate that year, though it was necessary at times to dump the finer sizes on the ground. Though the mines in 1920 were working, the operators' association kept up a continuous fight for a machine scale. During this year one of the operators obtained from the district president an agreement under which another type of machine was to be given a ninety-day trial, but no permanent agreement or scale was made.

With the opening of the coal season in the spring and early summer of 1921 the usual volume of orders was received for domestic sizes but no orders were entered for slack. As a result the operators renewed their demands for a machine scale more insistently and vigorously than before. This time the demand was from every operator, and the mines closed down.

During all these years the operators proposed scale

SPADRA FIELD AND IMMEDIATE SURROUNDINGS

Spadra lies not far from Fort Smith which is one of the leading junction points of the Southwest being served by the Missouri Pacific, the St. Louis & San Francisco, the Arkansas Central, the Fort Smith & Western, the Kansas City Southern and the Midland Valley.

after scale and made concession after concession and every reasonable change was made that it was thought would meet the views of the miners' officials, but it all seemed of no avail. The miners demanded a higher scale for machine mining than had been paid in shooting from the solid. In the matter of yardage especially the miners wanted a big increase in rates and the same rate for loading coal after the machines as was paid in solid shooting, thus leaving the cutting of the coal to be added to the solid-shooting rate.

After the summer was far advanced with no mines in the field operating, the miners' officials asked that negotiations be opened with a view to making a combination pick-mining machine rate, with the rate for cutting and loading hand-picked coal far higher than the solid-shooting rate we had been paying for mine-run coal. The operators declined to go into negotiation, insisting on their original and consistent demand for a machine scale on a mine-run basis based on the solid-shooting rate in effect with a differential of 7c. per ton which they had already conceded.

They looked on the suggestion to make a pick-machine scale as only a scheme to increase the mining rates and felt sure that after the machines were installed most of the miners would load mine-run machine coal, claiming it as hand-picked. Thus the rate would be much higher than for the coal obtained from solid shooting.

It also seemed to the operators that going to a hand-picked coal basis, in which the slack is left in the mines, would prevent largely the monetary advantage of introducing machines, for, though there would be an increase in the domestic sizes, there would be nothing received for slack, because on the hand-picked basis the rate was intended to be high enough to pay the loader for leaving the slack in the mine, and the figure was based on the percentage of slack he made on the solid-shooting system of mining. The mine owners considered also that leaving a large part of the product in the mine was a waste, contrary to good public policy.

As the summer passed with none of the mines in operation, the miners, too, commenced to ask why a machine scale could not be made, as the operators had repeatedly told them that they were ready at any time to make a fair machine scale. The matter had been presented many times to John L. Lewis, international president of the United Mine Workers of America, and finally he took action and appointed John P. White, ex-president of the United Mine Workers of America, as his personal representative to meet with the miners' and operators' representatives in Kansas City. After several conferences, due largely to the influence of Mr. White, a scale was finally adopted in September, 1921, nearly four years after the first demand for a machine scale had been made.

The old rate for mine-run solid-shot coal was $1.40½ per ton of 2,000 lb. with an increase for all coal mined from seams less than 2 ft. 9 in. in thickness. The new scale for machine work was as follows: Loaders, $1.13½, mine run; machine runners, 20c.; differential, 7c.; total $1.40½.

The operators had tried so long and so unsuccessfully to get a machine scale that most of them had nearly given up hope of ever getting one. When the scale was finally agreed to it came as a surprise. No one had found the courage to buy the mining machines and other equipment in advance of the scale except one company, which had purchased two machines on trial.

The season was so far advanced and it would take so long to procure and install the necessary equipment that only a few of the mines tried to operate in 1921 and those that did make the attempt ran only about ten days.

It is impossible to estimate the loss sustained by both the miners and operators by this long delay in making the scale. Both know, or should know, that they lost heavily on account of the protracted idleness and even more in the loss of patrons, who, due to the inability of the operators to furnish them coal in 1921, had been forced to use other kinds of fuel.

Now, however, all the principal mines of the field have installed machines. One mine uses shortwalls cutting along the bottom of the seam. In nine other mines the machines are a combination of shortwall and longwall. These work as shortwall cutters with the bar about on a level with the top of the machine body. This bar is supported by a sort of underframe. This places the cutter bar so that it can mine out the slate and band rock in the middle of the seam. Light shots bring down the upper and raise the lower bench. This plan greatly increases the percentage of lump, practically reversing the old proportion of the sizes. Machines also remove most of the band rock so that the cut is made in refuse material and not in good coal. As the result of their improvement in the regularity of the work and their better pay, even the miners are losing their former resentment.

The coal is cleaner, more of it is marketable, and it is expected that the running time each year will be much greater than it ever was before now that more lump coal is produced. Machines finally came when it seemed that the operators must have them or quit business. Perhaps they saved the field.

DEMONSTRATIONS OF THE EXPLOSIBILITY of machine coal cuttings have recently been made at the Pittsburgh, Pa., experiment station of the U. S. Bureau of Mines for the chief of the mining division of West Virginia. The explosibility of starch and aluminum dust was also recently demonstrated. A general program for the scientific study of the propagation of coal dust explosions, which has been given consideration, includes a study of the time factor in the combustion of coal-dust particles, and the method for determining pressure; also a study of the influence of ionization in the propagation of a dust explosion.

Refuse from Picking Table Crushed, Cleaned and Used In Boiler Furnaces at Graham, Ky.

Tipple Refuse Too Poor to Use for Raising Steam Passes Through Crusher and Over Reciprocating Table and Makes Salable Fuel at Cost of Less Than a Dollar a Ton

By Charles M. Means*
Pittsburgh, Pa.

THE relatively high cost of producing coal has introduced new and varied problems and warrants resorting to expedients that were impracticable a few years ago. The bituminous-coal industry is destined to follow the practice of the anthracite field in reclaiming valuable fuel from refuse piles and from the material separated from the product of the mine in course of its preparation for the market.

At the plant of the W. G. Duncan Coal Co. about 80 tons of refuse is separated every working day from the coal delivered to the tipple. This refuse contains so much impurity that without being cleaned it cannot be used for fuel in any known design of furnace. Consequently until recently it was the practice to remove this material to a waste pile at a cost of about 25c. per ton. The following analysis of the refuse shows that it contains much good coal that would burn if the impurities were in part removed:

CRUSHED REFUSE FROM PICKING TABLES

	Per Cent		
Moisture	5.50	B.t.u. per lb.	9,960
Ash	21.95	Sulphur, per cent	12.02
Volatile matter	32.87		
Fixed carbon	39.68		
	100.00		

Refuse Washing Plant

The coal from the picking tables is crushed and transported by the derrick to a bin, from which it is fed to a reciprocating table, where the coal is cleaned. The clean coal goes to the boilers or even to the market, and the waste, about 30 tons a day, is taken by trucks or railroad cars and dumped.

Concentrating Table

The refuse is classified into clean coal, slate and sulphur. The clean coal has the ash reduced from 22 per cent to 6½ per cent. The sulphur content, which ran 12 per cent, falls to 3½ per cent. The sulphur and slate at present both fall into a common bin and are dumped to waste together.

After an investigation it was decided that an attempt should be made to clean the refuse so that it could be used in a power plant owned by the same company and located near by. For its preparation a hammer-type crusher and a concentrating table were installed. A guyed derrick was erected and furnished with a clam-

*Consulting engineer.

shell bucket. This derrick removes the crushed tipple refuse from the crusher to a bin over the concentrating table and the coal from the washed-coal bin below that table to an elevated bin from which it is taken to the boilers. It is used also for transferring the refuse of the reciprocating table to trucks or railroad cars for disposal.

The refuse is delivered from the tipple to a bin over the crusher, to which latter it is fed as required. After the coal has passed through the crusher it falls into a bin beneath it. It is then removed by the derrick to another bin at the concentrating table, where it is fed onto the table and the separation of the coal from its impurities is made. The bone and sulphur fall into one bin, and the coal falls into another.

Derrick Always Ready to Place Coal as Needed

The coal is picked up by the clamshell and placed in an elevated bin and loaded by gravity into industrial cars and delivered to the power plant. However, if more of the cleaned product is being made than the power plant requires, it is stored in a pile, to be picked up when the mine is not in operation or at some time when the supply of refuse from the tipple is insufficient to meet the needs of the boiler furnace. The moisture left in the coal after its preparation is not excessive and has no deterrent effect on its use in the stoking equipment.

The analysis of the coal thus saved from the tipple refuse is as follows:

CLEAN COAL PREPARED FROM TIPPLE REFUSE

	Per Cent		
Moisture	7.40	B.t.u. per lb.	12,362
Ash	6.57	Sulphur, per cent	3.63
Volatile matter	38.68		
Fixed carbon	47.33		
	100.00		

The results attained in the burning of this product have always been as good as and perhaps better than are obtained from the combustion of the regular screenings from the mine. Some of the coal thus recovered has been shipped on regular orders for screenings, and no complaints have been received from any of those to whom such shipments have been made.

Sulphur Recoverable When Occasion Requires

The sulphur thrown off by the table goes into the same bin as the bone and shale but at a different point. It will be a simple matter to recover the sulphur separately and in a sufficiently pure state for the manufacture of chemicals. At the present time the market for this material is such that the separation of the sulphur hardly is warranted.

For the various operations two men are required, one at the derrick and one at the concentrating table and washer. The labor cost is 75c. per ton of recovered coal, the power cost about 5c. and the overhead about 10c., making a total cost of about 90c. per ton of coal recovered. In other words, the separated clean coal costs only about 65c. per ton more than the cost of disposing of it as refuse, the final result being that on an average 50 tons of commercial coal is recovered per day at a relatively low cost.

This equipment has been in use about two years and the results have proved uniformly successful under various operating conditions. It is reasonable to suppose that plants of this character can be installed at many mines throughout the bituminous fields and operated at a real profit.

Basic Average Figures on Anthracite Industry Made Available

By R. V. Norris

IN ITS foreword, entitled "The Vital Need—Information," *Coal Age* of Feb. 8 said: "Industry and the world at large require facts for safety. It is the function of the engineer to supply these facts."

In the series of articles by Mr. Ashmead on "Anthracite Mining Conditions," started by him in the Feb. 22 issue of *Coal Age*, a long stride is made in furnishing in available form basic average figures applying to the industry.

Mr. Ashmead has reduced to easily studied diagrams the figures as to thickness and depth of beds, boiler equipment, transportation and, most important of all, labor output in tonnage from analysis at five-year periods, from 1872 to 1922, of the very complete reports of the Inspectors of Mines of Pennsylvania.

From these diagrams can be traced the changes in the industry through half a century of progress. As would be expected, the average thickness of coal worked shows a general decrease, and of depth of workings an increase, modified in some sections by extensive strippings and second mining of old surface workings. The rather startling increase of two and one-third times in the tons produced per mule does not indicate that the hay burner has become two and one-third times as efficient but that he probably handles less than one-third of the output now compared with his monopoly in 1872.

In the labor efficiency a marked increase in tons per day per outside man reflects the improvement in machinery, particularly in the introduction of mechanical picking, replacing boys in the breakers. The reduction in efficiency of inside employees probably is partly due to conditions and partly to actual decreased effort.

Similar articles have been prepared treating each of the mining districts in the same general manner, so that the series gives a very complete history and analysis of practice, showing the fluctuations and changes of half a century of experience.

The value of the investigation lies not only in making available valuable data previously buried in a mass of reports but in showing the tendencies for the future and in giving a basis of comparison for different operations by showing the average conditions and requirements of each region in clear and easily studied form.

These curves can and should be used by all operators to check up their own production results by comparison with their regional averages, modified by comparison of their conditions with the regional curves of depth and bed thickness. The curves will be found of great value in studying property values and particularly in forecasting the results of future changing conditions.

This work of Mr. Ashmead shows what can be done in making readily available huge accumulations of statistics, and points to a valuable service which the government should do in making its collections of data available for practical use. With the way thus blazed by private enterprise the work should be continued and extended.

Additions, removals and changes in the permissible list of explosives from March 15 to Dec. 31, 1922 are given in Serial 2,430, by S. P. Powell, explosives engineer, which was issued recently by the U. S. Bureau of Mines. The list supplements that contained in Technical Paper 307, issued in March, 1922.

Administration of Laws Regulating Conditions in Mines*

Best Results Obtained by Appointing Inspectors Through Rigid Examination, Then Giving Them Real Authority and Reasonably Secure Tenure of Office—Supplementary Regulations Should Be Alterable to Suit Changing Conditions

By E. A. Holbrook†

OUR present mining laws and codes and their administration are a growth and evolution from the older mining customs and laws of Great Britain. Today, of the coal mining codes of the various states, the Pennsylvania bituminous code is the most complete and has been the framework for the provisions and administration practices of the codes of many other states. Pennsylvania has no mining code covering ore mines and quarries, and no code to regulate petroleum and natural gas production.

The best results in administration of mining codes have been gained by appointing inspectors through rigid examination, then giving them real authority and reasonably secure tenure of office. In any mining code, instead of a collection of detailed laws whose change is difficult, it is desirable to have a body of law, supplemented by regulations which may be altered by conference of all concerned, without legislative action.

The administrative relationships of the workmen's compensation insurance inspection and merit-rating work to the state mine inspection service are supplementary and may, in a state where mining is a great industry, be operated to advantage separately without conflict or duplication.

Time to Legislate on Coal Conservation

The time has come to consider introducing into mining codes factors affecting conservation in mining the irreplaceable resources, especially coal, to be administered under the public or state department. A great state department should contain specialists to investigate and advise in the varied engineering technical problems increasingly encountered in the administration of the mining codes.

In no way can greater help come in the administration of our mining codes than by the more systematic and general training and education of the masses of the men in the industry in the elements of mining science and art that are vital to their safety and advancement, and in upbuilding the industry.

A complete State Department of Mines should administer at least the following bureaus: (1) Coal-mine inspection; (2) ore mines and quarries inspection; (3) petroleum and natural-gas production inspection; (4) mineral conservation; (5) miners' compensation insurance; (6) miners' instruction and training; (7) mine engineering and research.

The subject as first suggested was "A Code of Standard Practices in the Administration of Mine Inspection Laws." I prefer the present title, for, due to the great diversity of state mining laws in this country and more particularly the coal-mining laws, codes or regulations as they exist in twenty-nine states today, no one man is qualified to recommend a best definite detailed code to cover the great differences in practices and administration occasioned by the multitude of different conditions underground.

The more one deals with the American coal industry, the more one becomes impressed with its vastness and complexity and realizes that facts and physical conditions important in one district or state often are of minor importance in another. In general, coal-mining codes vary from state to state, not only in completeness and effectiveness but in substance and in operation.

New Laws Should Be Outcome of Conference

Thus before devising acceptable codes of procedure or altering practices dealing with mine-inspection laws it is wise to bring together for extended discussion men in the industry with wide general experience, others familiar intensively with special local conditions, specialists in modern underground machinery and appliances, the miners and the operators as most directly concerned, the experienced inspectors and the representatives of the public. Modern mining codes based on these considerations have been put in operation within recent years in Great Britain and in several of our states.

Get clearly in mind that from the earliest days mining has been considered an industry apart and by itself, its people a group distinct from the general worker in many thoughts and habits, and that it was practically the first industry generally to have codes, regulations and inspection, especially as concerns the safety, health and working conditions of the employee and his relations to the employer. When men go underground, new and unfamiliar hazards appear, new problems concerned with the conservation of life and properties arise. One man's actions may endanger the life of every man underground in the mine.

New Conditions Call for New Legislation

Our modern coal-mining laws and codes are built mostly on older ones which had their beginnings several hundred years ago in the coal-mining districts of England. Here, as men dug deeper into the earth, local rules and customs developed as safeguards to property and life underground which after a time became in effect the common laws of mines. At first these laws dealt with property rights and had little regard for protection of life. It was not until 1850 that the laws providing for government inspection of mines were passed. In 1872 many of these common customs and laws were absorbed into a general coal mines act applicable to all of Great Britain, but with individual districts still able to regulate for special local conditions. Many amendments and additions have been made since, necessitated by the revolution in mining brought about by the introduction of modern machinery, and tending strongly in administrative features toward greater centralization of and increase in authority, duties and independence of the Central Department

*An investigation made for the Director of the U. S. Bureau of Mines and published with his consent.

†Dean of the School of Mines, Pennsylvania State College; formerly assistant director of the U. S. Bureau of Mines.

of Mines; and laying increasing emphasis on the fitness of inspectors and administrators of the laws, through competitive examinations for appointments to such positions.

In Germany the history of the origin and development of coal-mining codes has been similar excepting for a fundamental difference in administration policy —i.e., in Germany and other Continental countries a mine manager may not undertake any new action or work whatsoever without the approval of the government department, whereas in England the theory has been that an individual operating a mine could continue to use his own initiative and judgment in mine development and operation so long as he observed the minimum requirements of the law as found in the codes and regulations.

In this country, largely because our first miners came from the mines of Great Britain, we have developed our codes and their administration on the English theory and groundwork. The first state laws here governing coal-mine operation and inspection were passed for the anthracite district of Pennsylvania in 1869 after efforts extending over more than ten years, and were broadened by acts of 1870 and 1871. Ohio in 1874 passed the first acts providing for state inspection and regulation of bituminous coal mines. Next, in 1877, Pennsylvania enacted laws governing mine operations and providing for state inspection for the bituminous-coal region. This bituminous code, together with its many amendments and revisions, has been the basis for practically all the coal mining codes in the rest of the twenty-nine states where coal mining is an industry. Especially noteworthy in Pennsylvania have been the revisions of the code to meet the needs brought about by modern conditions of working and the introduction underground of new appliances. For example, the use of electricity, which as it develops brings new and unknown hazards underground, is more extensively covered by the Pennsylvania bituminous code than by that of any other state.

A Mining Code Must Contain Much Detail

While the length of a state mining code is not a safe measure of its value yet, other things being equal, it may give a measure of scope, attention to details and diversity of conditions to be administered. Thus the Pennsylvania bituminous law heads the list with about 43,000 words, followed in turn by Ohio with about 40,000, Illinois 36,500, and the other states in decreasing sequence. The new federal Bureau of Mines regulations to govern operations on the public domain coal lands of the West and to properly conserve the coal therein have about 19,000 words, but in part fit into and supplement the codes of the various states in which this mining is conducted, and are therefore not detailed as to many methods and duties generally considered in state codes.

The essential object sought in the American codes is the safety and health of the miner, with minor emphasis on protection of property. I venture to emphasize that the time has come to give more attention to economic factors in coal-mining codes, having the object in view of compelling more systematic and modern methods of mining coal in order to extract the largest possible percentages of the coal before abandonment of the mine. It is true that operators of some mines now extract all the coal possible and that others will follow when it becomes profitable to do so, yet should not the decision as to whether or not certain coal should be mined or lost be from the standpoint of conservation of an irreplaceable resource rather than from the economic profit viewpoint, and a matter to be entrusted to the public administrators of our mining codes? It would mean true conservation of our resource, hand in hand with our present efforts at conservation of life.

The administration of coal-mining codes is universally in the hands of a chief inspector, having greater or less power and responsibility, according to the state. He generally is appointed by the Governor of the state, without examination for fitness and upon his general record and reputation as a mining man, although a few states make definite technical qualifications a prerequisite. The chief is assisted by deputy or district inspectors, whose duties, powers, qualifications and fitness vary widely in the various states. Since the test of a law is its enforcement, the choice and methods of appointment of a state inspection service whose duties are entirely those of administration and enforcement of the laws are equally important with the provisions of the code itself.

Pennsylvania and Illinois Inspectorates

Following English custom, Pennsylvania was the first state to appoint inspectors based on examination for fitness. Later, as the number of inspectors increased greatly, the inspection service was brought under a State Bureau of Mines (1897) and then, with prophetic vision for the necessity of a greater service to handle the greatest and most specialized of the industries, a Department of Mines was created (1903). The Pennsylvania mine-inspector examinations have, as the industry developed, been made more severe, and are generally acknowledged as being of advanced high grade and models for the examinations of many other states. In Illinois the first mine inspections were made by county surveyors who were politically elected officers. Afterward in 1883, a state inspection service modeled on the Pennsylvania laws was enacted, without, however, doing away with the county designated mine inspectors. Some counties still have their own appointed inspectors, who, however, act as deputies to the state inspectors.

In 1901 for the anthracite districts of Pennsylvania the method of electing district inspectors from a list of those who had obtained certificates of fitness was put into operation. Recently (1921) the return was made to the appointive system after examination. The elective system of selection of inspectors has not been adopted generally, although in Oklahoma, following a provision inserted in the state Constitution in 1907, the chief state inspector and the district inspectors are elected as a part of the regular party ticket. In Kansas for a time the chief inspector was elected by elected delegates of miners, but since 1913 the appointment has come under a Commissioner of Labor and Industry.

For the country in general coal mining would today be a better and a safer industry were inspectors in every state chosen as for the bituminous region of Pennsylvania, through strict examination in principles and practice of mining, at a salary sufficient to attract high-grade men, and freed from any influence save those listed in the laws and that of their superior officer, and expectant of holding office until retired by natural causes. A high grade of inspection service should exist in all districts of the country and be backed up by putting "more teeth in the laws," by giving increased author-

ity to the inspection service and by pensioning its members when they can no longer perform the arduous duties exacted by the work.

It is encouraging to record that, even in the case of the chief, usually appointed by the Governor of a state, there has been a more marked tendency during the past few years to depend on merit for continuation in office. In one case recently a state Governor reappointed a chief inspector who had been appointed first by the preceding Governor of opposite political party. Maryland even provides for a permanent man to head the department who is appointed by the Governor from a list of five persons who have passed strict civil service examination for competency. British Columbia elects a Minister of Mines who has under him a complete organization whose members are removable only through cause. To my mind, a better mine-inspection service may be built up through continuity in office of men able to build and maintain firm policies through a considerable term of years rather than through the frequent changes taking place in some states. I am totally unable to see how matters that concern the life or death of a miner should concern politics.

Some Boards Group Mine with Other Safety

During the past few years the great new factor in the administration of mine-inspection and safety work has been the coming of workmen's compensation insurance for miners, its influence on mine safety and the relationships of the industrial commissions administering the compensation insurance and inspection to the administration of the established departments of mines and related inspection service. Thus, in Wisconsin, California, Utah, Ohio and in several other states in which mining is of minor importance the State Mining Bureau or Mines Inspection Service no longer constitute major departments reporting direct to the Governor but have been merged into a major department known as the Industrial Accident Commission or Bureau of Labor and Industry or by similar name, which generally combines mines, factories and other state inspection, together with the enforcement of the various workmen's compensation acts. On the other hand, Colorado, Illinois and Maryland in revising their state departments within recent years have kept their mine-inspection departments practically independent, although combining many forms of inspectional work.

The workmen's compensation insurance inspection is related to coal-mine inspection and mine safety as follows:

Attempts were made at first to insure mines, either through state funds or private companies by a straight tonnage tax or by a tax based on the payroll. This, while applicable for states having only a few mines of similar character, did not make allowance for the wide variations in hazards, as for example, between a small mine with safe natural conditions and a large badly operated mine with gas, a bad roof and possibly other natural and moral hazards. It was as if the same fire-insurance premium rate should be assessed on a fireproof structure and a wooden shack. Consequently the system of merit rating of coal mines for safety standards for purposes of equitably assessing compensation-insurance premiums was worked out by the Mining Department of the Associated Insurance Companies in co-operation with the U. S. Bureau of Mines, and the system has been adopted as the most equitable for coal-mining insurance. All known mine hazards are listed and charged for with allowance or deductions for their non-existence or elimination at the mine in question. Thus for the first time the direct cost of a mine with low safety standards is brought home to the operator. The system has proved a real safety incentive.

Considerable discussion has taken place as to the administrative relations of this compensation-insurance inspection work to the regular work of state inspection in a Department of Mines, and so as to the advisability of grouping it with the regular state mining department inspection work. Undoubtedly, in states where mining is a minor industry, requiring at most two or three inspectors, some form of amalgamation or co-operation with state accident compensation departments is feasible. Another good point is the argument that those who pass on safety are in the best position to pass on accidents.

One of the difficulties of the regular state mining codes is that generally they are laws enacted by the Legislature, and their change or repeal as mining conditions change often is a difficult matter. On the other hand, the states of California and Utah, with mine inspection grouped with the state accident or industrial commissions, have, instead of fixed mining law codes, a body of regulations arrived at after consultation of all interested parties, and they are fairly easy to change when new conditions arise. This desirable feature, however, need not be limited to states where the mine-inspection service is affiliated with the accident commission. Without regard to the organization of a State Mining Department, it is difficult to understand why, in a highly developed and specialized art like mining, courts and legislatures should have to be educated to the needs of the industry before changes in codes can be made. A real danger in amalgamation is that of having mining policies passed upon by men who are primarily not mining men.

Merit Rating Spurs Operator Only to Safety

A study of the question in any state where coal mining is one of the important industries shows that the functions of the state mining inspection service and the inspection of mines for insurance merit rating are supplementary rather than duplicating or overlapping. The insurance inspection is an incentive to the operator only to lessen his individual hazards by economic persuasion. It follows a regular schedule, has no police power and is special work for a special purpose. It is an added incentive to increase safety above the minimum standard rather than a basic one affecting all interests. Its basis is the business of insurance. On the other hand, the regular inspection service must enforce a code of mining requirements for safety based not on economic factors but on the relationship of human society in underground hazards and conditions. Its edicts must bind miner as well as operator. Its inspectors must have real police power. Their technical knowledge must govern and decide many points not involved in the compensation work. They must spend much time on the technical side of the work, in interpreting and applying all codes and regulations with justice. They are in fact the sheriffs of the mines, often with the added power of judge and jury. In addition there is still a gap in compensation inspection through the large companies electing to carry their own risks.

Before long state mine-inspection services should have a new duty to perform, that of conserving those

resources of coal which so much in the past have been wasted by careless mining, owing largely to economic factors beyond the inspectors' control at present. For the benefit of the coming generations, should not laws require the extraction of a maximum percentage of the coal resource before abandonment of a mine? A simple statement and yet its enforcement means building a new code of mining laws and a new conception of the individual right to mine, yet one which must come, even before it is profitable to take such care.

It is pertinent that other states with ore, mineral and clay mines and quarries comparable with Pennsylvania have special mine inspection services to serve them. Pennsylvania has none. Also California and other Western states have found it in public interest to provide state agencies to regulate petroleum and natural-gas production, technology and conservation.

You all know that Pennsylvania is the great coal-mining state of the Union, producing last year about 40 per cent of the tonnage of the country and the value of which was about one-half of the value of all of our coal. Pennsylvania alone produces more coal than any foreign country excepting Great Britain, and is scarcely behind her. Yet the technical side of the coal industry in Great Britain is recognized by a major department in the home office of the British Government with a Secretary of Mines. Surely in Pennsylvania with the technical mining problems, the enforcement of the laws and the industry itself becoming more important each day and requiring at present 55 inspectors, it is vital to maintain and build up a still greater Department of Mines.

Departments of Mines Should Have Experts

Under modern mining conditions a large state department of mines is called upon to decide complicated engineering and technical questions involving standards of electrical, mechanical and chemical appliances, of passing upon highly specialized machinery and eliminating its hazards. Problems increasingly arise calling for investigation and research in general and of local conditions involving mine gases, ventilation, mine supports and other special and often unknown factors. For this work the department should have at its command specially trained men with a knowledge of engineering and research in the mines.

I believe the greatest help in the administration of our mining codes must in the future come from more intensive instruction and education of the masses of men engaged in the industry. In Pennsylvania alone coal mining commands an army of nearly 400,000 men. Tens of thousands of new men are enrolled each year and in increasing numbers. This expansion of our coal industry has caused a scarcity of men trained in those elements in the science and art of mining which is rightly required by the Pennsylvania laws before a man may be a mine official or an inspector.

The introduction of machinery, the added dangers from gas and dust as our mines grow larger and deeper and the coming necessity of preventing waste of our great non-replaceable resource all demand more trained officials and miners. Practical men are needed, but the time necessary for them to become competent workmen and officials can be greatly shortened by instruction such as is common in most foreign coal-mining countries. This training to interest the men must in turn be given by practical mining men. It is useless to make mining codes and regulations which are beyond the grasp of the mass of people they affect. Looking to the future, administration of our improved and broadened laws and codes for increased safety and efficiency should first require that to every man and boy in the mines a place and way must be offered where he can, if he chooses, acquire under practical and trained men the knowledge necessary to safeguard himself and his fellow workers and to advance himself without limit in the various positions of responsibility in the industry.

Finally, to make complete any great state department by including in it all the related services mentioned in this paper, and to form a plan for building up and administering a service which must grow and expand, I recommend a central Department of Mines to include at least the following bureaus: (1) Bureau of Coal Mine Inspection, (2) Bureau of Ore Mines and Quarries Inspection, (3) Bureau of Petroleum and Natural Gas Inspection, (4) Bureau of Mineral Conservation, (5) Bureau of Mine Compensation Insurance, (6) Bureau of Miners Instruction and Training, (7) Bureau of Mine Engineering and Research.

Thirty-four States Have Fuel Directors

Of the forty-eight states in the Union all but fourteen have State Fuel Administrators or another official appointed by state authority to regulate the distribution of coal during the present emergency. In one of these fourteen states, Connecticut, the Administrator, T. W. Russell, recently sent his resignation to Governor Templeton.

The states having Administraters, with their names and addresses, follow:

State Fuel Administrators

Alabama—William A. Darden, State Fuel Administrator, Montgomery.
Delaware—Leon Walker, Chairman, Delaware Coal Commission, 1020 Church Street, Wilmington.
District of Columbia—Walter C. Allen, Executive Secretary, Public Utilities Commission, Washington.
Florida—Florida Railroad Commission, Tallahassee.
Georgia—James T. Boifeuillet, Commissioner, Georgia Public Service Commission, Atlanta.
Illinois—Robert M. Medill, State Fuel Administrator, Chicago.
Indiana—J. W. McCardle, Chairman, State Distribution Committee, Indianapolis.
Iowa—Charles Webster, State Fuel Administrator, Des Moines.
Kansas—Court of Industrial Relations, Topeka.
Kentucky—J. Sherman Cooper, Chairman, Kentucky Railway Commission, Frankfort.
Louisiana—John G. O'Kelly, Fuel Distributor for Louisiana, Baton Rouge.
Maine—Andrew P. Lane, State Fuel Administrator, Augusta.
Maryland — William Milnes Maloy, Chairman, Public Service Commission, Baltimore.
Massachusetts—James J. Phelan, Massachusetts Emergency Fuel Administrator, State House, Boston.
Michigan—William W. Potter, State Fuel Administrator, Lansing.
Minnesota—Ivan Bowen, State Fuel Administrator, St. Paul.
Mississippi—Mississippi Railroad Commission, Jackson.
Missouri—Hugh McIndoe, Chairman, Missouri Coal Distribution Commission, Jefferson City.
Nebraska—H. G. Taylor, Chairman, Nebraska State Railway, Commission, Capitol Building, Lincoln.
New Hampshire—Charles M. Floyd, State Fuel Administrator, Manchester.
New Jersey—Wm. J. Grier, State Fuel Commission, Trenton.
New York—General George W. Goethals, New York State Fuel Commission, 165 Broadway, New York City.
North Carolina—R. O. Self, Director, State Fuel Commission, Raleigh.
North Dakota—Frank Milhollan, Fuel Director and Distributor, Bismarck.
Ohio—George T. Poor, Chairman, Public Utilities Commission of Ohio, Columbus.
Pennsylvania—William D. B. Ainey, Chairman, Pennsylvania Fuel Commission, Harrisburg.
Rhode Island—George H. Webb, State Fuel Administrator, Providence.
South Carolina—Frank W. Shealy, Chairman, Railroad Commission, Columbia.
South Dakota—J. J. Murphy, State Fuel Administrator, Pierre.
Tennessee—Wilbur A. Nelson, Chairman, Tennessee Coal Commission, Nashville.
Vermont—Hugh J. M. Jones, State Fuel Administrator, Montpelier.
Virginia—Major Alexander Forward, State Fuel Administrator, Richmond.
West Virginia—J. Walter Barnes, State Fuel Commissioner, Charleston.
Wisconsin—P. H. Pressentin, Chairman, State Coal Committee, Madison.

The states besides Connecticut that have no Fuel Administrator are: Arizona, Arkansas, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oklahoma, Oregon, Texas, Utah and Wyoming.

What Shall Be Done About the Growing Evil of the Pollution of Streams by Mine Drainage?*

Review of Proposed Laws—Neutralization of Waters Discharged Into Ohio and Its Tributaries Would Require Even Today a Million Tons of Lime Yearly—New Mines Increase Acidity—Actions in Law Courts

By Andrew B. Crichton
Johnstown, Pa.

NO MORE important question has come before the coal industry in the past decade than the prevention of stream pollution by mine drainage; especially in Pennsylvania, where large areas of coal land have been developed. It may be thought that the problems of labor or lack of transportation outweigh in importance that of stream pollution. We can see possible remedies for labor and transportation problems but there is no known satisfactory solution of the mine-drainage problem. The subject has been given little serious attention, for until recently it has been little understood; but in the past year it was brought to the attention of the coal-mining industry by the introduction in Congress of several bills designed to prevent discharge of acid waters from mines or other sources into navigable streams or their tributaries.

The first legislation proposed was the Appleby bill, H. R. 7,369, designed particularly to prevent the oil pollution of coastal waters. It contained the following provisions, which the coal men regarded as applicable to the coal industry:

> It shall be unlawful to throw . . . any refuse matter of any kind . . . into any navigable waters of the United States or into any tributaries of any navigable waters from which the same shall float or be washed into such navigable waters.

The chemical, steel, paper and other manufacturing industries, as well as the mining industry, objected to this clause, the mine operators contending that it would prevent the discharge of waste or mine drainage into any waters of the United States, for all streams or tributaries finally reach navigable waters.

The next bill introduced was that of Congressman Briggs, H. R. 7,430, an amendment to Sec. 13 of the Pollution Act of March 3, 1899. The original act referred chiefly to oil and oil refuse, but it provided also "that no material of any kind should be deposited on the bank of a navigable water or tributary which might reach the waters and interfere with or obstruct navigation." This last provision could be said to apply to mine refuse, which would produce highly acid drainage.

The Rosenbloom bill, H. R. 8,733, also an amendment to the act of March 3, 1899, provides that it shall not be lawful to deposit or discharge from "any source whatever any free acid or acid waste, or anything that may become acid after being deposited into navigable waters or tributaries of the United States." Under this bill army engineers may prohibit the discharge or may regulate the entrance of wastes or may require the treatment of such discharge to destroy its acidity. This bill aims at the mine drainage entering the Ohio River and its tributaries.

The first draft was proposed by Major General Lansing H. Beach, chief engineer, United States Army. General Beach, in his report, states that the treatment of acid mine waters is so simple and inexpensive a matter that he believes there will be no opposition on the part of the owners of mines concerned. He suggests that lime be deposited in a small box, to be built at each mine opening, through which the mine water would flow, thus neutralizing the acid.

J. T. Travers, supervisor of streams, fish and game division, State of Ohio, in the same report states that the equipment will cost about $65 for each opening and the supplies from 75c. to $1 per day. It developed, however, at the hearing held in Washington that the Travers system was applicable only to manufacturing plants discharging 3,000 to 7,000 gallons per day.

Mr. Travers thinks that coal-mine drainage is not so bad as that from manufacturing operations and that it would be comparatively simple and inexpensive to treat mine drainage. He apparently has not considered seriously the statements of mining engineers as to the enormous quantities of acid mine water daily flowing from the coal mines of the country. There would be no opposition to treatment in this manner if the problem were as simple and inexpensive as indicated in the foregoing paragraphs.

Ohio Receives 2½ Million Tons of Acid

The Chemical Alliance, in a report made at the request of the chief engineers of the United States Army, stated that 6,500 tons of sulphuric acid is discharged into the Ohio River and its tributaries every day, or 2,357,500 tons per annum, or nearly half as much as is now produced in the United States. Neutralizing this amount of acid would require 3,250 tons of lime per day, or 1,170,000 tons per annum.

Charles Dorrance, vice-president of the Hudson Coal Co., whose thirty mines produce 9,000,000 tons of anthracite annually, has stated that these mines pumped 15 tons of water for each ton of coal produced and that neutralization of the water of the anthracite region, basing the estimate on the cost to this company, would require an initial expenditure for installation of $39,000,000 and that the annual operating expense would be about $18,000,000.

Mr. Dorrance estimated that the mine drainage from the fields of the anthracite region was 700,000 gallons per day; and that neutralization would add to the consumer's bill about 50c. per ton. P. C. Madeira, of the Anthracite Coal Operators' Association, estimated that an average of 18 tons of water was hoisted or pumped for each ton of coal.

The act of 1899 placed the matter in the hands of the army engineers, but at the Congressional hearing the question was referred to the Department of Commerce for investigation and report; thus at the start jurisdiction is rather confused. In Pennsylvania Governor Pin-

*Article entitled "Mine-Drainage Stream Pollution," presented at the February meeting of the American Institute of Mining and Metallurgical Engineers, held in New York City.

chot has promised legislation to prevent stream pollution. Various Congressional candidates have based their claim for election on this issue.

The problem of pollution is squarely before the industry. It is important, it is serious, and the difficulties of the situation should be understood by the country, and more reliable data should be obtained on which to base proper legislation. Otherwise laws will be enacted that will become a burden to industries and the people as a whole. Already stream pollution has been a cause of inconvenience and expense to both mining companies and to the public. Until rather recently stream pollution has been a mining-community problem. If a water supply was destroyed through mine drainage it was customary to go farther afield for a fresh supply.

Unable to Purify Water Satisfactorily

Attempts have been made and much money spent in the building of treatment plants, which have been unsatisfactory and later have been abandoned. Many communities have had their water systems polluted and have gone farther up stream, at great expense, for fresh supplies. Johnstown, Latrobe and McKeesport have had to abandon their original sources of supply. Barnesboro, Altoona, Connellsville and many other Pennsylvania towns have acid water during certain periods of the year and eventually must seek new sources.

Nearly all the important streams of central and western Pennsylvania which were used twenty years ago for water supply are now seriously contaminated. Pittsburgh, in the center of one of the greatest mining and manufacturing districts of the world, is a particularly glaring example of a city suffering from contaminated waters. As industry expands there is a constantly growing demand for pure water for both domestic and industrial purposes; at the same time the extensive development of coal mines in the vicinity produces more and more mine drainage. During a large part of the year the quantity of water drained from the mines is small compared to the quantity of pure water flowing into the streams above Pittsburgh, and the acid water is so diluted as to render it harmless. This period grows shorter and the period of contamination longer.

The headwaters of some of the streams lie beyond the coal measures, but practically all these areas have been developed and little more fresh water can be obtained from such points. Western Pennsylvania has been developed from the standpoint of mining without regard to future water supplies.

Sulphur Water Strongest in Dry Season

Areas underlaid by coal measures that have been developed and partly or completely mined have little runoff except in wet weather. The broken ground allows easy penetration of surface water, which is later pumped out or drawn from the mine carrying much acid with it. The drought of last summer emphasized the seriousness of the problem in the Pittsburgh district.

The state and individuals have spent much money to solve the problem, but without success. It seems time for wise and careful governmental action. Secretary Hoover suggests a careful investigation of the entire problem before the passage of any legislation whatever, but this must not be deferred too long or there will be litigation between the mining interests and those of the water works.

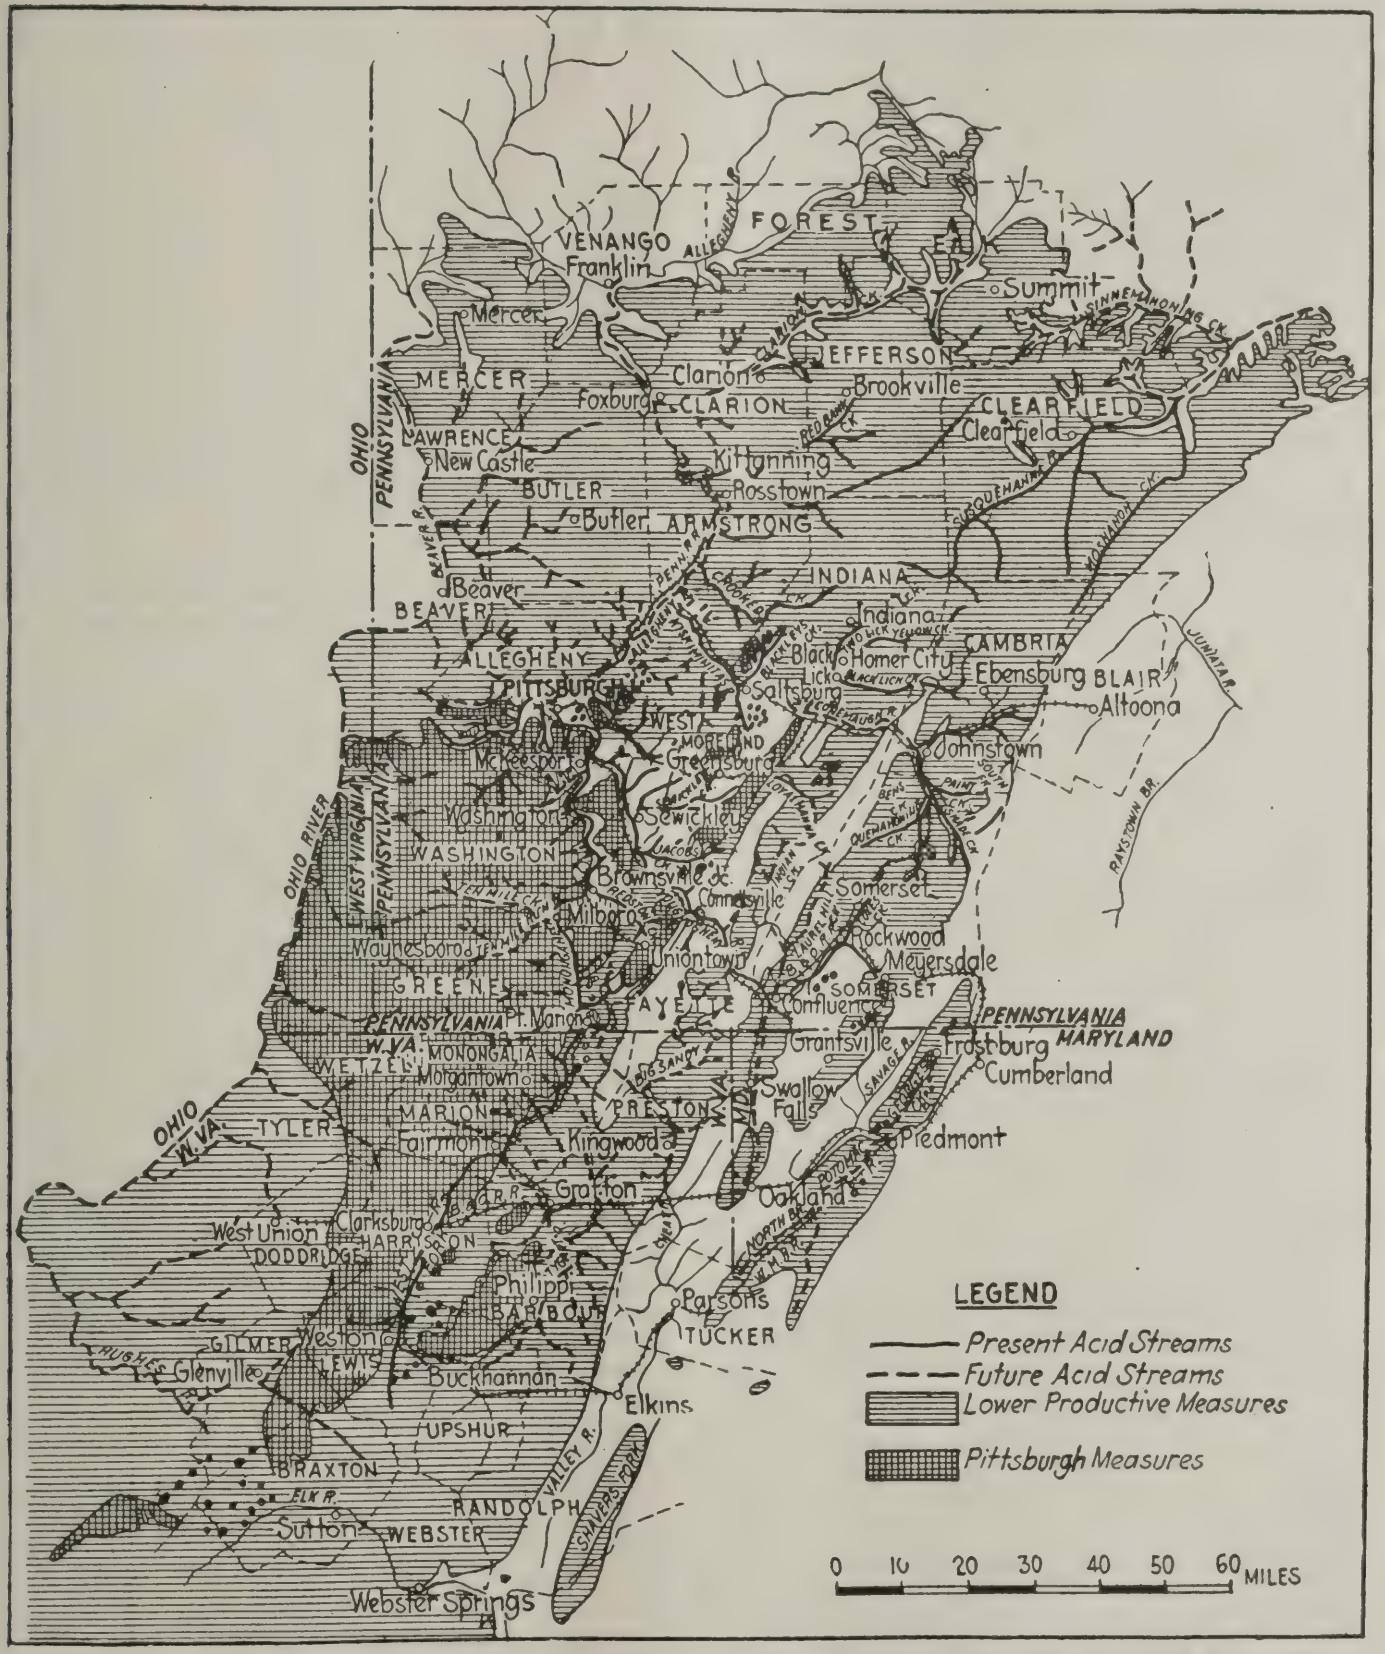
In the past the interests of the mining industry have been regarded as paramount; but while coal is a necessity, water is necessary for the industrial centers where the coal is used. Both are vital to the welfare and prosperity of the nation.

Mining has maintained its superior position to industry and the water supply of the latter partly through the decision of the Supreme Court in the Sanderson case, in 1886, which gave the Pennsylvania Coal Co. authority to conduct its work without interference by the plaintiff, who obtained his water below the exit of the mine and which maintained that the inconvenience to the plaintiff was not so serious as the closing of the mine would have been. At the same time, however, the Court pointed out that the case "may arise in which such pollution may become a nuisance, and public interest, as involved in the general health and well-being of the community, may require the abatement of the nuisance."

An important case involving stream pollution is now pending in the Court of Equity, Fayette County, Pennsylvania. In this suit the plaintiffs are the Mountain Water Supply Co., the Dunbar Water Supply Co. and the Pennsylvania R.R. About thirty operating coal companies are made the defendants.

The Pennsylvania R.R. about forty years ago gave up its water supply at Portage because of mine-drainage pollution. Several million dollars were spent to provide an adequate supply for the future needs of the company, and Indian Creek basin was developed to supply the southwestern portion of this system. The drainage area of this development is 110 square miles, half of which is underlaid by commercial coal measures, none of which were developed at that time. Since then, however, railroads have tapped this section, mines have been opened and the water supply polluted. This has rendered the situation serious. Careful study has been given to all factors entering into the problem: methods of mining, thickness of seams, drawing of pillars, pitch of the measures, the relation and quantity of water pumped to production of coal, the relation of rainfall to underground water, etc.

Old Mines Produce as Much Acid as New



It developed that percolation of water bore no relation to the quantity of coal produced but a direct relation to the extent of development. It depends directly on the extent of the surface that has been disturbed and on the decrease in the run-off owing to the ground thus broken, because for each acre of coal mined much more than an acre of surface becomes disturbed and subject to increased penetration by surface waters.

The records of 170 mines in central Pennsylvania showed that for each acre worked out, 100 to 10,000 gallons of mine water is discharged per day, the average being about 1,100 gallons. In other districts of the state the average was not far from this amount. Shallow workings produced much more than the deeper workings. Many mines produced their maximum only when the pillars were drawn and when, as a result, the surface subsided.

Except in shallow workings, mine drainage flows are quite constant. They do not vary much with rainfall, consequently in time of drought the percentage of acid in the streams is materially increased. In one area, where about half the coal had been removed and where the average depth was about 500 ft. and the rainfall 3,300 gallons per acre per day, it was found that 27 per cent of this water percolated into the mine and was pumped out as acid water. The minimum flow was only 17 per cent less than the average of the year. These

figures are not far from the average percolation in other districts where records have been carefully kept.

The quality of mine drainage is quite as important as the quantity. In practically all the coal mines the mine waters contain sulphuric acid. Of over 300 mines examined in central Pennsylvania in only four was the mine water free from acidity, and in these the absence of acid probably was due to the fact that limestone was in contact with the coal seams. While nearly all seams of coal contain iron pyrites, in the thin seams of central

BITUMINOUS-COAL REGIONS IN PENNSYLVANIA AND NORTHERN WEST VIRGINIA WITH REFERENCE TO PRESENT AND FUTURE STREAM POLLUTION BY MINE WATER

The streams that are already acid are marked in solid lines and those which are expected to become acid with time in broken lines. It will be seen that Mr. Crichton has little hope for any of the streams in the coal area. He paints a gloomy picture of the industrial future and of the social discomfort that will arise from the gradual acidification of the streams.

and western Pennsylvania there is a bone coal carrying a high percentage of sulphur at the top of the main seam, a large portion of which is thrown into the gob, though large quantities are hauled outside and dumped in the valleys. This refuse material, both outside and inside of the mine, oxidizes rapidly and furnishes a large quantity of acid. The sulphuric acid forms salts as it comes into contact with the soluble minerals present and these salts in turn, on exposure, are precipitated, forming insoluble coatings which permit the free acid and salts to flow farther down the stream.

Some mines in the Pittsburgh seam in the Greensburg district of Pennsylvania show free sulphuric acid as in Table II.

The average total acidity at sixty mines of the H. C. Frick Coke Co. was 100 gr. per U. S. gallon. Analyses of the waters of some of the polluted streams in Pennsylvania at much above minimum flows, are given in Table III.

In treating acid water the custom is to neutralize it with lime (converting it into hard water—that is, converting the acid into calcium and magnesium sulphates) then adding soda ash to soften it. The quantity of foreign matter in solution is about the same as before softening. It is the total quantity of sulphates rather than the free acid which governs the treatment.

Twelve Grains of Acid the Working Limit

Water with 4 gr. of sulphates per gallon requires treatment of the same kind, and when pollution exceeds 12 gr. per gallon the amount of soda ash required causes foaming. Treated water is not free from harmful effects, the presence of salts still causing pitting. The human system could stand more than 12 gr. of sulphates per gallon, but a water cannot be said to be healthful if it is contaminated to this extent.

Basing an estimate on the area of coal mined throughout western Pennsylvania, Maryland and West Virginia tributary to the headwaters of the Ohio River and using the average percolation of such mine areas, it is estimated that there is an excess of 5 gr. per gallon of sulphate in the river water which requires softening before using. To this, however, must be added the acid derived from refuse dumps.

In this district over 7,000 square miles are underlaid with coal, only 400 of which have as yet been mined. If the mining of 400 square miles produces water of the foregoing character, what must be in store for the rivers when ten or twenty times this area has been mined? In the past the acid waters have been largely neutralized by the natural alkalinity of the fresh waters, but once the acid exceeds the neutral point the depreciation in the quality of the water will be markedly increased and out of proportion to the area of coal development. The illustration shows the coal fields of western Pennsylvania and parts of Maryland and West Virginia; it also shows the part underlaid with coal; in solid lines the streams now acid and in dotted lines streams that probably will become acid with continued mining.

Sewickley Creek at Hunker	40.27	9.80	16.33
Turtle Creek at Wilmerding	48.40	16.33	8.75

In addition to the acid of the mines large quantities enter the rivers from various industrial plants. If all this impurity were neutralized with lime the amount of sludge resulting would be very large and the arrangements necessary to keep it from the streams would be no small item of expense.

With this general statement of the problem what are the suggested remedies? Water-softening plants will help postpone the evil day, but the step from 4 gr. of sulphate to 12 gr., where softening is no longer effective, is short, and other remedies must be sought.

What shall be done with abandoned mines that are constantly throwing quantities of acid drainage into the streams? In time all the pyrite may be exhausted, and the water again may become pure. One case has been reported where the mine ceased to produce acid water after it had been abandoned twenty-five years. It does not appear as if we could wait for time to purify the water. Sealing the abandoned mines has been suggested, but this is impracticable in fractured ground. Where the ground can be thoroughly sealed, keeping out air and keeping the pyrite under water, oxidation will certainly be diminished. This plan holds some hope. It has been suggested that mine drainage be conducted from the mines in non-destructible pipes to points on water courses, below which the water is not used for manufacturing purposes. As a practical proposition this is difficult, because the drainage deposits sediment that would tend to clog any system of piping

that could be used. An open drainage or a concrete duct would offer a better medium than any piping.

In the West barium has been used quite successfully to soften water, but its cost is excessive and water so treated is not suitable for domestic purposes. Evaporation is the only really satisfactory method of converting contaminated waters into something that can be used, but the cost is prohibitive.

The building of large storage reservoirs for impounding fresh water for the purpose of dilution has been proposed, but this would be expensive and of only temporary benefit. In the past the problem has been solved by going farther up stream to unpolluted sources, but in many instances no such sources are now available. The water companies have asked that coal mining cease in certain areas, and this the courts still have under advisement. It is certain that coal-mine development cannot be carried on without destroying the water of the immediate vicinity. It would, therefore, seem that about the only means of conserving the water supply is to stop coal mining in those little-developed areas which still contain an ample supply of fresh water. This cannot well be done as between individuals.

The State Board of Health in Pennsylvania reports ninety-six water companies with acid-pollution problems. This problem is connected and might well be considered with the matter of the overdevelopment of the coal industry. The coal industry is not to blame for this condition; it is simply a development of that industry. The public must either suffer the inconvenience or meet the cost of combating it.

We cannot learn from Europe how this problem may be handled because on that continent the coal mines do not have a similar problem. In Great Britain many of the mines use their water for boiler purposes and without treatment. In Yorkshire mine drainage is used as a source of domestic supply. In Great Britain the mines are being worked at depths varying from 1,000 to 4,000 ft. and they have relatively little water; in some of them water must be taken underground in order to lay dust. British coal mines are not acid producing because the coal is low in sulphur and often is in contact with limestone. In France the mines do not produce acid water, probably because an overlying bed of chalk extends from the surface to a depth of 300 ft.

With less than one-tenth of the coal of western Pennsylvania worked out, with continued mining, as at present conducted, and new development constantly being started, it is apparent what the results to the streams will be in a comparatively short time. The mine-drainage steam-pollution problem is serious. Its extent is not fully realized by the industry or the public. Secretary Hoover's suggestion that the question be carefully investigated in order to determine possible remedies and legislative enactment is wise and should be heartily approved and receive the co-operation of the coal industry.

Compare Coal Analyses of 25 Laboratories*

By A. C. Fieldner,† H. M. Cooper‡ and F. D. Osgood§

A STUDY of results obtained in analyzing similar samples of coal and coke by twenty-five laboratories throughout the country was recently conducted by the U. S. Bureau of Mines in comparison with results obtained in the bureau's coal laboratory at Pittsburgh, the purpose of this work being primarily to obtain a comparison of the methods of coal analysis used by the laboratories of the American Gas Association. Therefore, four standard samples of coal and one of coke were prepared in the Bureau of Mines coal laboratory at Pittsburgh, and portions were sent to each laboratory. At the same time, a like number of standard samples were submitted to twelve commercial laboratories not affiliated with the association, for the purpose of comparing their analyses with the results obtained by the U. S. Bureau of Mines and the American Gas Association. The comparison is based on the average of twenty-four analyses by the Bureau of Mines on each kind of coal, and the accompanying curves show the deviation from this average analysis, together with deviations from the check limits of the American Society for Testing Materials.

The laboratories co-operating in this standardization work are as follows:

AMERICAN GAS ASSOCIATION LABORATORIES

The Barrett Co., New York.
Boston Consolidated Gas Co., Boston, Mass.
Brooklyn Union Gas Co., Brooklyn, N. Y.
Camden Coke Co., Camden, N. J.
Chemical Service Laboratories, West Conshohocken, Pa.
Consolidated Gas Co. of New York, New York.
Henry L. Doherty & Co., New York.
Koppers Co. Laboratories, Pittsburgh, Pa.
Milwaukee Gas Light Co., Milwaukee, Wisconsin.
New England Fuel & Transportation Co., Boston, Mass.
Peoples Gas Light & Coke Co., Chicago, Ill.
Charles H. Tenney & Co., Boston, Mass.
United Gas Improvement Co., Philadelphia, Pa.

COMMERCIAL LABORATORIES NOT AFFILIATED WITH AMERICAN GAS ASSOCIATION

Perry Barker, Boston, Mass.
Commercial Testing & Engr. Co., Chicago, Ill.
Consolidation Coal Co., Fairmont, W. Va.
D. J. Demorest, Ohio State University, Columbus, Ohio.
O. L. Kowalke, University of Wisconsin, Madison, Wisconsin.
Arthur D. Little Company, Boston, Mass.
S. W. Parr, University of Illinois, Urbana, Ill.
Pittsburgh Testing Laboratory, Pittsburgh, Pa.
H. C. Porter, Philadelphia, Pa.
Public Service Electric Co., Newark, N. J.
U. S. Testing Co., New York City.
Warner Laboratories, Cresson, Pa.

The samples were carefully prepared by H. M. Cooper, chemist in charge of the Bureau of Mines coal laboratory at Pittsburgh, assisted by F. D. Osgood and W. H. Miller. The series consisted of twenty-four bottle samples each of an anthracite coal, a byproduct coke, a semi-bituminous Pocahontas coal, a low-sulphur low-ash Elkhorn Kentucky coal and a high-sulphur high-ash

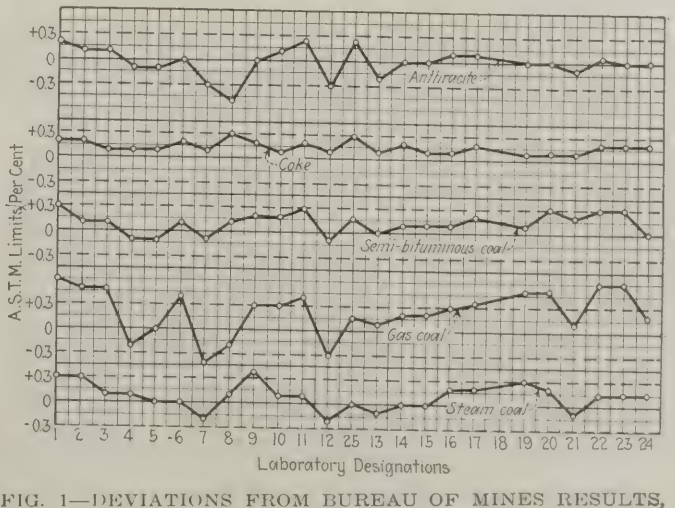

FIG. 1—DEVIATIONS FROM BUREAU OF MINES RESULTS, MOISTURE, AS RECEIVED

*Report submitted by A. C. Fieldner, chairman of Subcommittee on Analysis of Coal and Coke, American Gas Association, published in the *American Gas Association Monthly*, January, 1923.

†Superintendent, Pittsburgh experiment station, U. S. Bureau of Mines. ‡Chemist, U. S. Bureau of Mines. §Assistant chemist, U. S. Bureau of Mines.

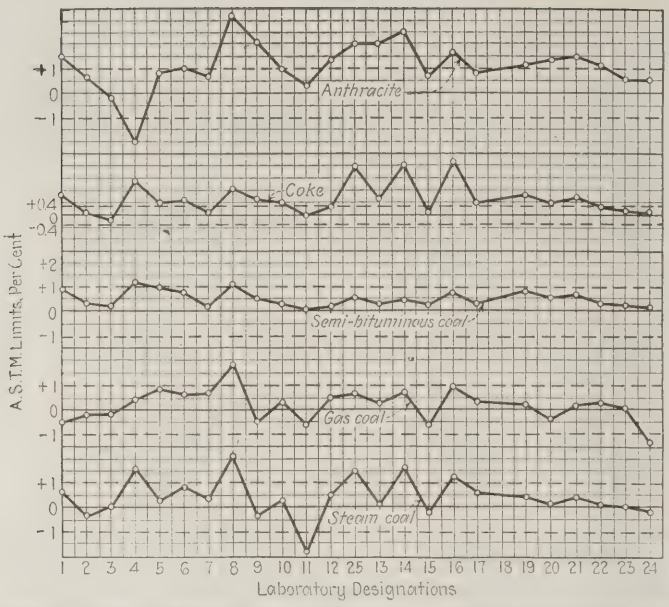

FIG. 2—DEVIATIONS FROM BUREAU OF MINES RESULTS. VOLATILE MATTER, AS RECEIVED

Pennsylvania steam coal. Laboratory No. 8 split its samples into equal parts, giving one part to laboratory No. 25 and retaining the other part.

In order that the samples would be as nearly representative as possible, the gross sample of approximately 10 lb. was thoroughly air-dried, then ground in the ball mill and passed through a 60-mesh standard sieve, after which it was mixed on a rubber cloth and quartered in the usual manner. Approximately an aliquot portion was taken from each quarter for each bottle sample.

Each bottle sample was then analyzed separately by the Bureau of Mines and transmitted to the various laboratories for analysis. The Gas Association laboratories were advised that care should be taken in determining the B.t.u. and ash content of the anthracite and coke samples on account of the tendency of incomplete combustion. They were also advised that if comparable results were to be obtained, the American Society for Testing Materials methods must be strictly followed in determining the volatile matter. These methods, as published in the *Gas Chemists' Handbook*, were not used in all the laboratories, however.

Curves showing the moisture variations are presented in Fig. 1. As a whole, the moisture determinations on the samples show good work on the part of the chemists, only 13 out of 120 determinations being outside of the check limits, and 10 of these are on the gas coal. Apparently considerable trouble was experienced with gas coal, where only 19 of the 24 laboratories are above the zero line, and 4 below and 1 checking.

Noting this tendency, the moisture was redetermined by the Bureau of Mines chemists on five additional samples of each class of coals and coke, which were held in reserve. There was no indication from these results obtained that the moisture content had changed after standing for two months. The general tendency of all determinations was to be above zero line, 85 being above, 19 below, and 16 an absolute check. The common copper drying oven and majority of electric ovens are not adapted for this determination, owing to irregular temperature and lack of proper air circulation.

Curves showing variations in the volatile-matter determinations are presented in Fig. 2. A great improvement is shown in the volatile-matter determination over the results shown in previous co-operative work. As was expected, the results on the anthracite and semi-bituminous coals and the coke sample fall above the zero line, with the exception of three determinations. The gas and steam coals are found to be on both sides of the line, 35 being above and 13 below.

Out of a total of 120 determinations, 40 do not check;

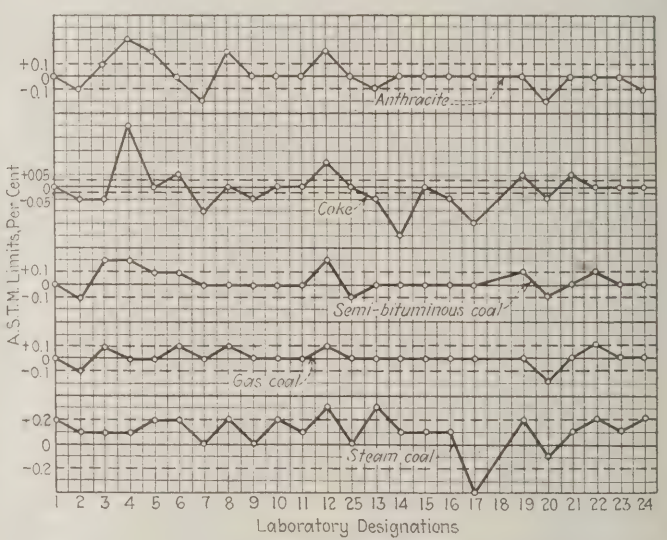

FIG. 1—DEVIATIONS FROM BUREAU OF MINES RESULTS. SULPHUR, AS RECEIVED

37 of the latter are above the limit line, and 26 of the 37 are on the anthracite and coke, which is conclusive proof that greater care is required on low-volatile materials such as anthracite and coke.

Laboratories 2, 9, and 25 reported the preheating of the sample at 105 deg. C. before making the determination of volatile matter and laboratory 21 reported the use of 20 drops of alcohol in making this determination on the coke sample. On studying the results of these laboratories it is found that this procedure did not give them any more consistent results, and past experience has not shown such modifications to be necessary. The results showing the greatest variation can be traced to the use of large crucibles with flat or loose-fitting covers.

Curves showing ash variation are presented in Fig. 3. The ash determinations show exceptionally good work on the part of the chemists, as only 5 out of 120 determinations are outside of the checking limits. Three of these results are on the coke, one on the

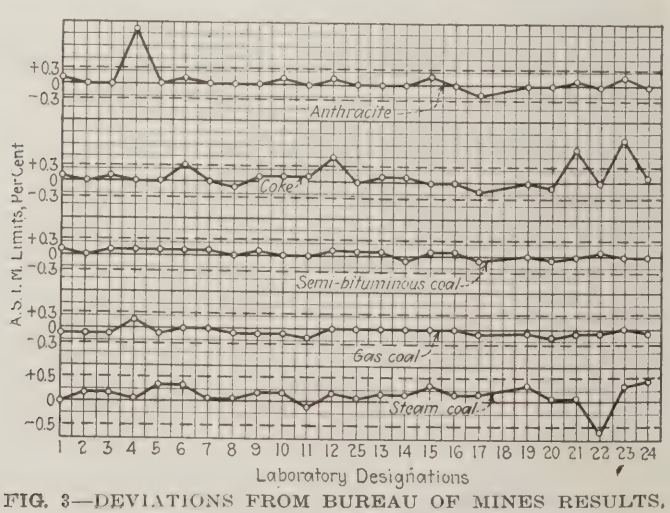

FIG. 3—DEVIATIONS FROM BUREAU OF MINES RESULTS, ASH, AS RECEIVED

anthracite, and the fifth on the steam coal. The first four probably are due to incomplete combustion, as the results are very high, and the other was ashed at a temperature of 1,000 to 1,050 deg. C., which result is low.

Curves showing sulphur variations are presented in Fig. 4. With the chemical knowledge available on sulphur one would naturally expect closer agreement of the results than is indicated by the curves, but out of the total of 120 results, 27 are outside of the checking limits. Sulphur from gas burners probably is responsible for some of the high results.

Should the checking limits on coke be increased from 0.05 to 0.1 per cent, nine of the results that fall outside of the limits would then be within the A.S.T.M. limits.

Curves showing the variations in the B.t.u. determination are presented in Fig. 5. The results obtained on the determination of heating value are very satisfactory. Much closer results were obtained on the whole series than in the previous series; 38 determinations out of 110 do not check, of which 12 are on coke, and the remainder about evenly divided between the other four classes. The widest variations are due to nickel-lined bombs and incomplete combustion, especially in the anthracite and coke samples. Evidently the warning, calling to the attention of each of the gas Association laboratories the difficulties that might be expected with these samples were not observed by some of the chemists.

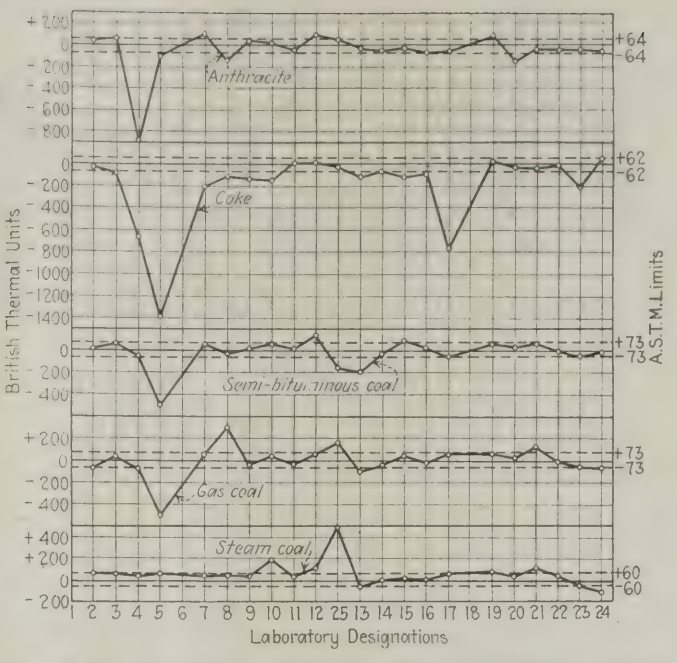

FIG. 5—DEVIATIONS FROM BUREAU OF MINES RESULTS, BRITISH THERMAL UNITS

Standardization Factors Must Be Correct

It is noted that some of the laboratories failed to make the proper corrections for acidity, sulphur, thermometer, etc. The operator can only hope to obtain the best results when these corrections are correctly applied and his standardization factors are absolutely correct. Nickel linings have no place in calorimetry and if reliable information is expected they must be discarded.

The results obtained indicate a closer application of the A.S.T.M. methods outlined in the *Gas Chemists' Handbook* than in previous comparisons. It is essential that all of the laboratories of the Gas Association as well as other coal laboratories use the standard methods in their coal work to insure accurate analysis of the fuel. Attention is called to the following points:

(1) Dry air must be circulated through the moisture oven at a sufficient rate to change the volume of the oven three to four times per minute.

(2) The best results are obtained for the determination of volatile matter when a 10-c.c. capsule-type crucible with a well-fitting cover is used. The electric furnace is superior to the Meeker burner for consistent work.

(3) The use of open burners is likely to give high results with manufactured gas in the sulphur determination. Sulphur determined from bomb washing will invariably run low, varying in proportion to the amount of sulphur present.

(4) More attention should be given to the proper application of corrections for acidity, radiation and sulphur in the calorimeter determination. The calorimeter bomb should have an inner surface of platinum, gold, porcelain enamel or other material not attacked by nitric or sulphuric acids or other products of combustion.

Nickel linings should not be used if results checking within A.S.T.M. limits are desired.

Problems of Operating Men

Edited by James T. Beard

Should the Fireboss Be Blamed or Did His Lamp Fail?

Knowledge of Conditions Not Applied in Practice —Fireboss Killed When Removing Gas—Lamp Had Become Heated Causing It to Pass Flame

IN reading the interesting letter of W. H. Moore, *Coal Age*, Jan. 25, p. 184, we are reminded again of human fallibility, in respect to safety-first on the part of men holding the most responsible positions in coal mines. Mr. Moore, however, does not appear to blame his fireboss, but attributes the accident to the failure of the bonneted Wolf double-gauze lamp the fireboss carried.

The letter gives the account of the Wakesiah explosion that cost the lives of the fireboss and a pumpman. The extent to which the writer of the letter blames the dead fireboss is found in the words with which he prefaces his remarks. He states: "Notwithstanding all knowledge of the principles and conditions affecting the use of safety lamps in practice, . . . that a safety lamp is not safe under all conditions."

Bureau of Mines Investigated Safety Lamps

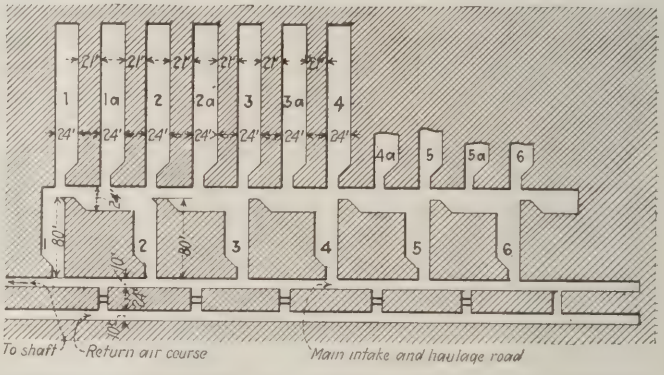
Attributing the cause to the failure of the lamp, Mr. Moore closes his letter with an appeal for further investigation of the action of safety lamps in explosive mixtures. He seems to forget or, perhaps, he has never seen the bulletin issued by the Federal Bureau of Mines, giving in great detail the series of experiments performed by the bureau on safety lamps under all conditions. These experiments were the most recent ones then performed under true mine conditions and have since been supplemented by the experiments of Prof. H. B. Wheeler, in England. What more, then, is to be done than to follow out in practice the lines laid down by these experimenters?

It is unnecessary to rehearse the account of this sad occurrence at the Wakesiah mine, which Mr. Moore has given in full detail in his letter. From the account given by him as manager of the mine, it appears that the lamp carried by the fireboss was found to be properly assembled and in perfect condition, following the explosion in the mine.

Lamp Failed Because of Overheating

However, the later examination of the interior of the gauzes showed that they had been exposed to intense heat, which was not apparent on the outside of the gauze. The conclusion seemed inevitable that the lamp had been used for illuminating purposes too long and had become heated, which caused the flame to pass through the gauze and ignite the gas outside of the lamp.

One of the lessons to be learned from this account is the need of applying what knowledge we have regarding the action and use of safety lamps, in our daily practice in the mine, and shelve for a time the possibility of a bonneted double-gauze Wolf safety lamp failing when properly used.



James Ashworth,
St. Augustine, Fla. Consulting Engineer.

Modified Double-Room Method

Plan suited to avert possible squeeze—Rooms driven on 90-ft. centers connected at face by cross-rooms—Intermediate rooms turned off cross-rooms—Advantage of the system.

REFERRING to the inquiry of Robert Holt, *Coal Age*, Feb. 1, p. 226, who asks for an expression of opinion as to whether there will be less liability to development of squeeze if the drawing back of the pillars, in a panel of thirty rooms, be delayed until the panel is complete when all the pillars can be drawn back together. Or, would it be better to draw back each pillar as the rooms reached the limit?

Judging from the information given and in the light of my own experience in working the Miller seam,

METHOD PROPOSED TO AVOID DANGER OF SQUEEZE

unless the rooms are driven quite narrow and wide pillars are left for the support of the roof, there is strong probability that a squeeze will result from the extraction of the coal in the rooms. The pillars will be crushed so that a comparatively small percentage of pillar coal can be recovered with safety.

Under this depth of cover, 250 ft., and with the conditions that prevail characteristically in the Miller seam, I would recommend trying the system of driving the first rooms turned off the entry on 90-ft. centers and connecting these by cross-rooms turned at a distance of 90 ft. from the entry and driven parallel thereto as indicated in my sketch. Other rooms are then turned off these cross-rooms, midway between the first set of rooms.

There is thus formed a system of advancing rooms, each 24 ft. wide with 21-pillars between them, as shown in the figure. The first rooms, turned on 90-ft. centers, are numbered 1, 2, 3, etc., while the intermediate rooms turned off the cross-rooms are numbered 1 *a*, 2 *a*, 3 *a*,

etc. This arrangement affords solid blocks of coal, approximately 80 ft. square, as entry stumps, which amply protect the entry and permit the drawing back of pillars, as quickly as each block of rooms is finished.

In the figure, I have shown rooms driven up in blocks of seven rooms, each. Care must be taken, however, to work a sufficient number of rooms in a block to give an area large enough to allow the roof to break readily. The breakline should be kept as straight as possible to avoid undue crushing on any of the pillars.

After the miners and their helpers have become familiar with this system, they will begin to appreciate its advantages. The work is easily handled; there is little danger of squeeze or creep occurring and a minimum of rock to handle by reason of that fact. The system will be found to guarantee a maximum recovery of coal. The expense for yardage is also reduced to a minimum. FRANK PARDOE.

Washington, Pa.

Certain Details in Humidifying

Shaft bottom and portion of main haulage road must not be neglected—Radiator system expensive to install and maintain—Direct method of applying steam better.

THE question of humidifying a mine ventilated on the exhaust system has proved an interesting one to the readers of *Coal Age*, judging from the references made to the manner of overcoming the annoyance of introducing steam into the intake which is also the haulage road in the exhaust system of ventilation. These references appeared in the issues of Dec. 21, p. 1000 and Dec. 28, p. 1043.

There are a few points, however, bearing on these methods of humidifying the mine air to which attention may well be called. In the first place, the plan of introducing the steam into the intake at a point a considerable distance inby leaves the shaft bottom and a portion of the main haulage road dry and dusty, and they receive no benefit from the steam introduced at the point beyond.

In this regard, let me say that this portion of the mine should not be neglected. I would suggest that a branch pipe be laid through the crosscut at the shaft bottom by which a portion of the steam can be conducted into the haulage road at that point, every night when the presence of the steam would not be as objectionable as during the day when the mine is running.

DAMPENING AT INTERVALS INJURIOUS TO ROOF

This should be done every night without exception and not at more or less frequent intervals when it is thought the place needs to be dampened. Nothing is more injurious to a slate roof than a constant change from a dry to a wet condition, which would result if the operation was only performed at intervals. The same injurious effect will be produced on the timbers, causing their more rapid decay.

Speaking of warming the air by the use of radiators, this plan may prove efficient when the air volume is small. The use of radiators to heat large volumes of air entering the mine will prove both expensive and cumbersome. The action of the steam on the air through the radiator walls is too slow and better results are obtained by direct contact as when the steam is blown into the air through an expanding nozzle.

My experience proves that blowing the steam into the air by a nozzle pointing in the direction in which the current is moving accomplishes the double object of warming and humidifying the air in one process and the air is cleared in less than one half the distance required by the use of radiators and bafflers or curtains.

It is important that the nozzle should be tapered outward properly to produce the best results by expanding the steam to the atmospheric pressure as it issues from the nozzle. A better distribution of the steam in the air is thus obtained.

COST OF RADIATOR SYSTEM EXCESSIVE

Such a nozzle is easily made and at little expense. It only needs to be screwed into the end of the pipe line when needed to be used. At other times, it should be put away in a dry place where it can be found when needed again.

On the other hand, the first cost of a radiator system far exceeds that of a nozzle. Moreover, unless the radiators and pipes are taken apart on the approach of the summer season and stored away in a dry place, they will be in no condition for use the following winter. Even the use of galvanized pipes gives little better results, as corrosion eats away the metal where the pipes are threaded. Iron pipes last a little longer than steel. Brass, of course, is better but too expensive.

Where live steam is used, the automatic regulation of the flow of steam from the pipe line, by means of a thermostat, will be found a great money saver, as live steam is expensive. In winter, it is nothing unusual for the temperature of the air to vary from 20 deg. or lower during the night to 40 or 50 deg. at midday. It is clear that much less steam is required to saturate the air at times under these changes of temperature. MINING ENGINEER.

Sealing Abandoned Areas Safest Practice

Arguments for and against sealing off abandoned areas—Conditions must determine question of sealing—Need of constructive suggestions—How seals should be built.

RECENT disastrous explosions have focused much attention on the hazards of the mining game. It would add greatly to the peace of mind and future happiness of those whose lot is to toil underground, if a satisfactory plan could be worked out to guard against the menace of gas in mines.

During the past few months, writers of *Coal Age* have dwelt much on this subject. Strong arguments have been offered to show that worked-out areas should never be sealed, but should be ventilated in a manner that will keep them free from dangerous accumulations of gas. On the other hand, many have argued in favor of sealing off such areas.

SEALING ABANDONED PLACES SAFEST PRACTICE

The subject of sealing abandoned places is an important one in the mining of coal. It is worthy of serious and broadminded consideration. Doubtless one's experience will largely modify his views. My own, in mines generating large quantities of gas, has led me to favor the sealing off of abandoned areas as being the safest practice.

However, I frankly admit that the question must be determined very largely by the general conditions exist-

ing underground, particularly the nature of the roof and floor of the seam. These conditions will often forecast the probability of the occurrence of squeeze, which has an important bearing on the matter of sealing.

Even so, it hardly seems commendable to leave extensive areas open for the free circulation of air, when a shorter and more direct route can be had by sealing off such places. The question has been discussed at length by other writers and little can be said, except what would be mere repetition and help not a whit in deciding the matter.

We need suggestions that are constructive and have regard to the best methods of building the seals, should this be decided on as necessary. While I know many will prefer to ventilate areas that have been worked out and are standing, my own conviction is that such territories should be sealed.

Essential Points in Building of Seals

Assuming then that seals are to be built, allow me to suggest a few essential points in their construction. First, it is absolutely imperative that solid bottom be found before the wall is started. Cracks in the bottom must be dug out, until solid formation is reached. I have known instances where the ditch had to be dug 8 or 10-ft. deep.

Hitches must then be cut 2 ft. into the solid rib coal and the equally solid roof above. These cuts should be started at a width of 2½ ft. and offset at the back of the cut, say 8 in. deep, the offset having a width equal to two cement blocks. This manner of cutting into the rib allows the builder ready access to the corners, where the greatest care must be exercised to see that every crevice is filled.

The ditch in the floor is filled with a good cement concrete, fluid enough to flow into every nook and crevice. Time is given for the concrete to set well before starting the wall, which is built up of a double thickness of concrete blocks, carefully laid in cement and tightly sealed along each rib and at the roof. A 2-in. pipe with a screw-cap must be built into the wall near the top of the seal, as a means of enabling the testing of the condition of the gas-charged air behind the seal.

Well Built Seals to Be Constantly Watched

After the seal has been completed, it must be watched, from day to day, to observe whether any settlement has taken place. If cracks develop these must be carefully plastered. In one instance that I recall, a gob fire had started in an accumulation of fine coal and slack piled with some timber near a gas wall that sealed an opening.

This wall was 40 ft. from the airway and leaking gas. The latter would accumulate and every few minutes flame would shoot across the entry in an alarming manner. This continued and, at intervals, there was heard a resounding zoom, as one explosion followed another. It is easy to imagine the feelings of those who had to contend with this danger and to realize that the situation had to be handled with much care.

In the building of seals in the manner described, ordinarily little trouble was experienced during the first year. However, owing to subsidence or squeeze occurring inside the wall, the utmost vigilance was required the second year, as the accumulated gases would be forced through the seals under high pressure. Then, let me say, woe betide that community should someone in charge sleep at the switch.

May I add, in closing, that none but thoroughly experienced and trustworthy men should be charged with the examination of a mine, each morning—examiners who will put the lives of others ahead of their own. We must remember that the night may bring to the home the blackened remains of a husband, father or brother who went out in the morning happy in the thought that he could provide the necessaries of life for those depending on him. Such a thought should suffice to stimulate every man to the greatest vigilance in the desire to avert disaster and lower the accident rate in our mines, which has been growing.

Panama, Ill. Alexander Bennett.

Inquiries Of General Interest

Flow of Water in Pipes

Explaining formula for calculating the flow of water in a given pipe, under a given head. Three factors determine total head producing the flow.

Having occasion, recently, to refer to my old friend, *Trautwine's Handbook for Engineers,* in search of a formula for calculating the amount of water that will flow through a given pipe, in a certain time and under a given head, I was puzzled to understand the formula given, which read as follows:

$$h = \frac{fl}{d} \times \frac{v^2}{2g} + \frac{1.5v^2}{2g}$$

Kindly explain this formula and say why the first two terms are multiplied together instead of being added, as is the last term and as it seems to me they should be. Also, show the same formula expressed in terms of the diameter (d) of the pipe; and the flow of water (G) in gallons per minute. Student.

Windsor, Pa.

The formula given is either wrong or copied wrongly. The first sign in the second number should be a plus sign like the last. The three terms should express, respectively, the friction head, velocity head and entrance head. But the entrance head, due to the water entering is always assumed to be one-half the velocity head, which would make the coefficient of the last term 0.5, instead of 1.5 as given above.

The corrected formula expressed in terms of d and G, asked by the correspondent, assuming a coefficient of friction for mining practice $f = 0.01$, is as follows:

$$h = \frac{lG^2}{800d^5} + 0.0026\,\frac{G^2}{d^4} + 0.0013\,\frac{G^2}{d^4}$$

$$= \frac{G^2}{d^4}\left(\frac{l + 3.12d}{800d}\right)$$

Or, solving for G, gives for the flow of water in gallons per minute, under the head h,

$$G = d^2\sqrt{\frac{800dh}{l + 3.12d}}$$

When the diameter of the pipe in inches is less than its length in hundreds of feet the second term in the denominator can be dropped with only slight error.

Examination Questions Answered

Miscellaneous Mine Examination Questions

(Answered by Request)

QUESTION—*In a mine subject to sudden outbursts of gas, what precautions would you take to prevent loss of life? What warnings usually precede outbursts of gas?*

ANSWER—When working a seam of coal subject to outbursts of gas, it is well to drive the places narrow, in the first winning, and give plenty of time for the gas to drain off before drawing back the pillars. Another precaution that may assist in relieving the situation is to drill numerous holes into the ribs and faces of the coal for the purpose of draining the gas on that portion of the seam. Where the cover is not too great, large boreholes can be sunk from the surface, at points in advance of the working faces in the mine.

Outbursts of gas are often preceded by ominous sounds that the miners call "bumps." These sounds are caused by the settlement and readjustment of the strata, resulting from the working of the gas toward the opening driven in the seam.

QUESTION—*In a mine the quantity of air measured in the return is 165,000 cu.ft. per min. (a) The return current contains 3 per cent of firedamp (marsh gas), what quantity of gas is given off in this mine? (b) What is the least decrease in the quantity of air that will render the return air explosive? (c) What increase of gas will (likewise) render the return air explosive?*

ANSWER—(a) The volume of gas in the return current is $0.03 \times 165{,}000 = 4{,}950$ cu.ft. per min.

(b) Assuming the lower explosive point of this gas is reached when the proportion of gas to air is 1 : 13, the quantity of air in circulation to produce that condition would be $13 \times 4{,}950 = 64{,}350$ cu.ft. of air. Then, the volume of air entering the mine is 165,000 — 4,950 = 160,050 cu.ft. per min. In order to reach the lower explosive limit of the gas, this volume must be decreased 160,050 — 64,350 = 95,700 cu.ft. per min.

(c) In order to produce the same condition by an increase of gas, the volume of gas generated must be $160{,}050 \div 13 = 12{,}311$ cu.ft. per min. This would call for an increase of 12,311 — 4,950 = 7,361 cu.ft. per min.

QUESTION—*What is the weight of 250 cu.ft. of marsh gas, barometer 30 in., temperature 65 deg. F.?*

ANSWER—Taking the specific gravity of marsh gas as 0.559, referred to air the same temperature and pressure, the weight of 1 cu.ft. of marsh gas, at a given temperature and pressure is

$$0.559 \frac{1{,}3273 \times 30}{460 + 65} = 0.0424 \text{ lb.}$$

The weight of 250 cu.ft. of this gas would then be $250 \times 0.0424 = 10.6$ lb.

QUESTION—*Explain the action of the Burrell gas detector.*

ANSWER—This instrument consists of a small brass tube connected at the bottom with a gage glass. At the top of the brass tube is arranged the combustion space containing a wire bridge that can be made incandescent by the current from a small electric battery. In use, water fills both the brass tube and the glass gage up to the level of the zero of the scale. By blowing gently into the rubber tube attached to the top of the glass gage, the water in the gage is depressed and rises to fill the combustion space at the top of the brass tube and is held at that level by pinching the rubber tube. The instrument is now raised to the point where a test is to be made for gas. Releasing the rubber tube draws the gas into the combustion space as the water level in that tube falls. The valve through which the air enters is now closed and the electric current turned on for a minute and a half, in which time all the gas that may be present in the air is consumed. The instrument is then shaken to cool the air remaining in the tube, after which its volume is measured on the graduated scale, which is calibrated to show the percentage of gas present.

QUESTION—*If the quantity of air passing into a mine is 75,000 cu.ft. per min., at a temperature of 50 deg. F. and the quantity measured in the return is 82,000 cu.ft. per min., at a temperature of 75 deg. F., what quantity of the increase is due to expansion from the increase in temperature and what quantity is due to the gases given off in the mine, neglecting barometric conditions?*

ANSWER—Disregarding any change in barometric pressure, the volume of air varies as the absolute temperature. Then, calling the increase volume due to the rise in temperature from 50 deg. to 75 deg. F., we have

$$75{,}000 \frac{460 + 75}{460 + 50} = \frac{75{,}000 \times 535}{510} = 78.676 \text{ cu.ft.}$$

The increase due to expansion is, therefore, 78,676 — 75,000 = 3,676 cu.ft.

Finally, the total increase as measured in the return being 82,000 — 75,000 = 7,000 cu.ft., the increase due to the gases given off in the mine is 7,000 — 3,676 = 3,324 cu.ft.

QUESTION—*Is it possible to have an explosion in a mine where the safety lamp gives no indication of firedamp?*

ANSWER—Yes. A mine generating much fine dust, particularly if the coal is highly inflammable, is liable to an explosion occurring by the ignition of the dust suspended in the air current and exposed to the flame of a blownout shot or any flame of sufficient volume of intensity. Although it is not necessary that any gas should be present, the explosion is more liable to occur if a small percentage of gas is present that gives no indication on the flame of a safety lamp. Under these conditions, every precaution should be taken to avoid the accumulation of fine dust at the working face and on the roads and traveling ways, and every means should be used to prevent the suspension of the dust in the mine air.

QUESTION—*In an air current 6 x 8 ft., in sections, and 5,500 ft. long, what is the velocity of the air current when the water gage stands at 2 inches?*

ANSWER—The sectional area and rubbing surface of this airway are respectively, $a = 6 \times 8 = 48$ sq.ft.; $s = 2(6 + 8)5{,}500 = 154{,}000$ sq.ft. The pressure due to a 2 in. water gage is $2 \times 5.2 = 10.4$ lb. per sq.ft.

Finally, substituting the given values in the formula for the velocity of an air current, we have

$$v = \sqrt{\frac{pa}{ks}} = \sqrt{\frac{10.4 \times 48}{0.00000002 \times 154{,}000}} = 402.6 \text{ ft. per min.}$$

Will Illinois Operators Consolidate? And What About Frank Farrington?

Consolidation of the three operators' associations of Illinois is again being discussed hopefully by at least one group of operating interests within that state. The matter got a good deal of consideration in January immediately after the national settlement with the United Mine Workers and was frankly urged by a few men as a measure to strengthen the operators' position in labor relations as well as to spare the officers of the present associations the expensive and tiresome consumption of time from their personal business.

"Is Frank Farrington the man to be labor commissioner for such a united association?" is a question which comes up immediately in these discussions. "I should say not," one group of operators invariably replies. But there are others not so positive. Various other men are suggested as the logical candidates for such an important work, though it is difficult for anyone to suggest a man sufficiently gifted with "super-diplomacy" to draw together all the interests in that turbulent state and satisfy even a bare majority.

It is openly declared by men in the 5th and 9th District Operators' Association that the whole scheme would be nothing but a maneuver to put the mastery of the state in the hands of the operators of the southern Illinois field on a tonnage voting basis. The response is that southern Illinois has no such designs because the voting basis might be shifted to that of membership instead of tonnage, thus putting the power in the hands of the other regions of the state as opposed to the southern field.

In spite of the stirring up of waters just now it is well known that a serious effort will be made to draw together as much of the state as possible into a single operators' labor organization even if it means only the consolidation of the Central Illinois Operators' Association with the stronger Illinois Operators' Association, made up largely of operators in the great southern field of the state.

French Charge Germans with Bad Faith in Matter of Coke Supplies

The necessity of buying British coke at high prices has caused the Société des Coke de Hauts-Fourneaux, the pooling agency for the sale of metallurgical coke to French blast furnaces, to cancel as of Feb. 15 the price fixed for February delivery (Franco-German frontier basis) of 110 fr. up to 40 or 50 per cent of the capacity of consumption of the furnaces and 155 fr. beyond that. The new prices decided upon are 150 fr. and 200 fr. respectively. This action was made necessary by the inadequacy of coke supplies from Germany for the French blast furnaces and is one of the grievances of France against that country.

M. Robert Pinot, vice-president of the Comité des Forges de France, in a recent interview laid stress on the fact that one of the last notes of the German Government explicitly declared that "Germany was ready to supply French metallurgists with all the coke they needed, provided only they paid for it direct to Germany." It is contended by French metallurgists that there could have been no plainer confession of Germany's bad faith in this matter.

Would Require Certificate of Competence For Bituminous-Coal Miners

A bill introduced in the Pennsylvania House of Representatives by Representative James T. Heffran, Washington County, provides that there shall be established in each of the inspection districts in the bituminous-coal region of the state, a miners' examining board to consist of nine miners who shall be appointed by the Governor as soon as the measure becomes a law and every two years thereafter. These boards shall examine all persons desiring to qualify as miners. Each member of the board shall be a miner with at least five years' practical experience. Upon his appointment he will serve for two years and his compensation will be $7.50 a day for each day served in connection with the work of the board.

The dates for the meetings of the board shall be advertised in two newspapers in each district and monthly meetings are provided for. These meetings will be public and any person desiring to become a bituminous-coal miner shall be examined as to his fitness for the work. Certificates of competency will be issued to all those who pass the examinations. The certificate will entitle a miner to work in any other district in the bituminous field, provided he is registered in the district to which he removes.

Each applicant must have had at least two years' experience as a miner and he must answer in the English language at least twelve questions pertaining to the requirements of a practical miner. The fee of each applicant is fixed at $2 while a registration fee of 25c. will be charged where a miner moves from one district to another.

No person will be permitted to work as a bituminous miner after Jan. 1, next, without having obtained a certificate, unless he is actually engaged in mining at the time the bill becomes a law, when he will be entitled to registration without examination upon producing satisfactory proof that he has been employed in any bituminous mine for a period of two years.

Rocky Mountain Coal Men in Winter Meet

The winter meeting of the Rocky Mountain Coal Mining Institute, held in Denver, Colo., Feb. 26, 27 and 28, was the most successful in years from the standpoint of attendance, entertainment and technical data presented. More than one hundred members registered, mostly from the states of Colorado, Utah, Wyoming and New Mexico.

An organization meeting was held Monday morning at the call of President F. W. Whiteside. The afternoon session was devoted to the reading of papers by A. L. Jones, district engineer for the General Electric Co., on "Electrical Problems in the Coal Mine," and by C. E. Drennan, electrical engineer for Hendrie & Bolthoff Manufacturing & Supply Co., entitled, "Why Alternating Current?" Both papers were of considerable interest and were thoroughly discussed. Extracts from papers and discussions of the whole program will be found in later issues of *Coal Age*.

Two hundred and fifty members and their ladies assembled in the banquet room of the Albany Hotel early in the evening for the banquet and "high jinx." Harry F. Nash, vice-president of the Oakdale and the Alamo coal companies, as toastmaster, introduced the speaker of the evening, George Sanford Holmes, of the *Denver Times*. The "high jinx," a fictitious meeting of the "Fact-Finding Commission," was put on by certain members of the Institute and was roundly applauded. A dance was enjoyed afterward.

On Tuesday morning F. A. Young, chief engineer of the St. Louis, Rocky Mountain & Pacific Co., presented an unusually interesting paper, "Air Cleaning of Coal at Brilliant, N. M." This was followed by "Pulverized Fuel," written by T. H. O'Brien, general manager of the Inspiration Consolidated Copper Co., but read by the secretary in Mr. O'Brien's absence.

In the afternoon Charles M. Schloss read the paper prepared by D. Harrington, supervising mining engineer of the U. S. Bureau of Mines; James C. Rae, general superintendent of the Owl Creek Coal Co., and himself, entitled, "Mining the Pitching Vein at Gebo, Wyo." The paper included the showing of moving pictures taken of this unusual operation. This was followed by moving pictures of rock drilling. Tuesday evening many members of the Institute went to the Orpheum Theater.

The Wednesday meeting was devoted to several short discussions and to the unanimous election of the following officers: President, George B. Pryde, general superintendent, Union Pacific Coal Co., Rock Springs, Wyo.; vice-president from Colorado, W. S. Getchell, superintendent, Walsen Mine, Colorado Fuel & Iron Co., Walsenburg; vice-president from New Mexico, W. D. Brennan, general manager, Phelps Dodge Corporation, Dawson; vice-president from Utah, Frank N. Cameron, general manager, Utah Fuel Co., Salt Lake City; vice-president from Wyoming, E. S. Brooks, vice-president and general manager, Union Pacific Coal Co., Rock Springs; secretary-treasurer, Benedict Shubart, Lindrooth, Shubart & Co., Denver, Colo.

Bituminous Coal Stocks Gain 2,000,000 Tons in Month; Higher Consumption Rate Lowers Days' Supply

Commercial consumers had in storage on Feb. 1, 1923, according to a survey undertaken by the Bureau of the Census and the U. S. Geological Survey, under authority of the Federal Fuel Distributor, approximately 38,000,000 tons of soft coal. This was 2,000,000 tons more than the stocks on Jan. 1, 1923, and represents a total increase of 16,000,000 tons since Sept. 1, 1922, when mining was resumed in the union fields that had been affected by the strike. Strictly comparable records are not available, but from the data at hand it is obvious that stocks on Feb. 1 must have been less than on the corresponding date in years for which statistics on stocks exist.

Measured in tons, stocks increased 5.5 per cent between Jan. 1 and Feb. 1. Measured in terms of days' supply, there was a decrease of 7.7 per cent, due to the increase in the rate of consumption in January. Assuming that the stocks were evenly divided, the supply on Feb. 1 was sufficient to last 24 days, against 26 days on Jan. 1. Such assumption may be made only for comparative purposes, however, as stocks are never evenly divided.

The trend of production has been downward during February and it is doubtful if stocks have increased perceptibly, if indeed there has not been a decrease.

Stocks on the Lake docks, classed as coal in transit, were 2,355,511 tons. Reports from a group of producers show that 730,000 tons of soft coal were in storage at the mines or at points between the mines and consuming centers.

Reports from byproduct coke plants indicate that there is no longer a surplus quantity of coke in storage. On Feb. 1 there were 146,000 tons on hand, which represented only a normal working supply.

Stocks of anthracite in the yards of retail dealers on Feb. 1 were 13 per cent less than on Jan. 1. The quantity of anthracite on the Lake docks was 68 per cent less than on the first of the year.

ESTIMATED TOTAL COMMERCIAL STOCKS OF BITUMINOUS COAL IN THE UNITED STATES *a*

(Net Tons)

Oct. 1, 1916	27,000,000	Aug. 1, 1921	41,100,000
Oct. 1, 1917	28,100,000	Nov. 1, 1921	48,500,000
July 15, 1918	39,700,000	Jan. 1, 1922	48,000,000*b*
Oct. 1, 1918	59,000,000	March 1, 1922	52,500,000*b*
Day of the Armistice	63,000,000	April 1, 1922	
Jan. 1, 1919	57,900,000	At least	63,000,000*bc*
April 1, 1919	40,400,000	Sept. 1, 1922	22,000,000*b*
March 1, 1920	24,000,000	Oct. 1, 1922	26,000,000*b*
June 1, 1920	20,000,000	Nov. 1, 1922	32,000,000*b*
Jan. 1, 1921	45,800,000	Jan. 1, 1923	36,000,000*b*
April 1, 1921	39,500,000	Feb. 1, 1923	38,000,000*b*

(*a*) The figures for 1918 in this table are based upon an actual count. Beginning April 1, 1919, the figures are estimates based upon reports from a selected list of 5,000 consumers whose stocks in 1918 bore a known relation to the known total stocks. (*b*) Subject to revision. (*c*) No canvass of consumers was made on this date. The total stock was estimated from the stock on March 1, ascertained by questionnaire.

From the foregoing table and the graphic presentation of the same data in Fig. 1 it is seen that coal flowed into storage during January at approximately the same rate as in the last two months of 1922. To those who have been watching the current statistics of production, it may seem surprising that only 2,000,000 tons were added to stocks in January, when production was nearly 4,000,000 tons more than in December. As a matter of fact, an appreciable part of the January production had not reached its destination on Feb. 1, and it could not therefore be taken into account in reckoning stocks. The most important factor which tended to keep stocks from reaching a higher level was a sharp increase in the rate of consumption. It is estimated that consumption plus exports during January was approximately 47,400,000 tons, or at the rate of about 10,700,000 tons per seven-day week.

Fig. 3 shows graphically the variation in stocks in each state. The map shows the days' supply held at general industrial establishments excluding steel and byproduct coke plants. This is the largest group of consumers and the one that shows best the distribution of stocks. Changes in activity in this group are quickly reflected in the coal market, and likewise changes in the coal market soon become apparent in the reserve stocks of industrials.

Taking the country as a whole, the stocks held by general industrials were sufficient to last 36 days. This was a decrease of 4 days from the supply on Jan. 1, 1923. Comparison with dates during preceding winter seasons for which records are available shows that on Feb. 1, 1923, stocks were lower than on any date except March 1, 1920. In six states only, Connecticut, Rhode Island, Louisiana, Oklahoma, Washington and the Northern Peninsula of Michigan, would the supply have lasted 60 days or more. In 15 states the supply was sufficient for less than 30 days.

Reports from the electric utilities indicated a slow accumulation of reserve coal, and the supply on Feb. 1 was sufficient to last 35 days. This was lower than the quantity usually on hand during the winter months.

As usual, the coal-gas plants had stocks much larger than any other class of consumers. On Feb. 1 such plants had on the average a 63-day supply, or more than two and a half times the average for all consumers combined. In ten states where coal gas is manufactured the plants had at least a 60-day supply.

Incomplete returns from byproduct coke and steel plants indicated an increase of about 10 per cent in the tonnage on hand. Owing to the increase in the rate of consumption, however, the days' supply—22 days—was the same as on Jan. 1. Steadily increasing activity in the steel industry has been responsible for a rapid increase in stocks of coal at byproduct coke and steel plants since the end of the miners' strike on Sept. 1, 1922. It is estimated that the total quantity on hand on Feb. 1 was no less than 112 per cent greater than on Sept. 1. The total stocks held by these two important classes of consumers has now reached a level where it compares favorably with the supply on dates when stocks were largest. The supply on hand Feb. 1 was 16 per cent less than on Jan. 1, 1922, 20 per cent less than on March 1, 1922, and 29 per cent less than on Jan. 1, 1919, when stocks at such plants were at the highest level recorded during the period over which stock statistics extend.

Estimates of railroad-fuel stocks, based on reports submitted by the American Railway Association, place the total quantity held by the railroads in stockpiles, cars and chutes on Feb. 1 at 7,573,000 tons, a supply sufficient for 18 days. In comparison with Jan. 1 this was an increase of 12 per cent.

Outside anthracite-burning territory the situation was

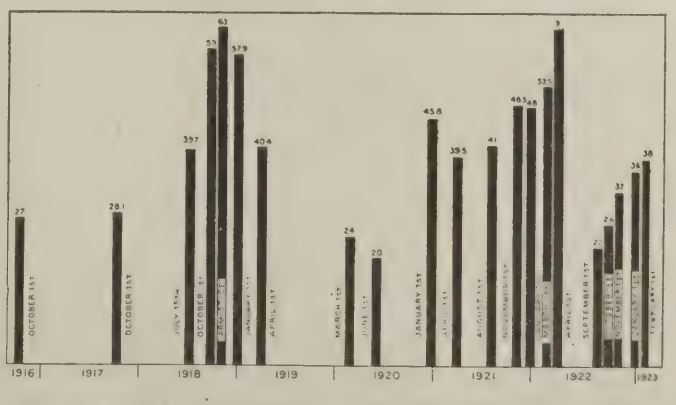

FIG. 1—TOTAL COMMERCIAL STOCKS OF BITUMINOUS COAL, OCT. 1, 1916, TO FEB. 1, 1923

Figures represent million net tons and include coal in hands of railroads, industrial consumers, public utilities and retailers. Coal for steamship fuel, on Lake docks, and in transit is not included. Figures for 1922 and 1923 are subject to revision.

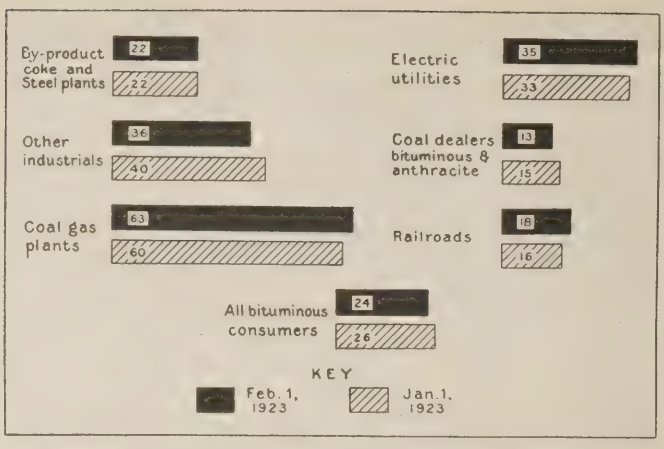

FIG. 2—DAYS' SUPPLY HELD BY DIFFERENT CLASSES OF CONSUMERS ON FEB. 1, 1923, AND JAN. 1, 1923

At the rate soft coal was burned in January, 1923, the stocks on hand Feb. 1 were sufficient to last 24 days. The stocks on Jan. 1 were sufficient to last 26 days at the rate of consumption in November and December, 1922. Thus, owing to the increase in the rate of consumption during January, the larger stocks on Feb. 1 were sufficient for 2 days less time than the stocks on Jan. 1.

as follows: Stocks increased perceptibly in the Middle Atlantic States and in the coal-producing states north of Tennessee and west to Utah. In New England and in the Southern and Gulf States stocks decreased. Despite the increases in many states. in only six was the supply sufficient to last 30 days or more.

It is estimated that during January there was an increase of at least 1,500,000 tons in the tonnage moving to consumers, and which was not accounted for in their reports.

Drafts on the stocks of bituminous coal on the commercial docks of Lakes Superior and Michigan totaled 760,152 tons. There were no receipts and the tonnage on hand declined from 3,129,206 tons on Jan. 1 to 2,369,054 tons on Feb. 1. In comparison with the stocks on the corresponding date a year ago there was a decrease of 61 per cent. These figures do not include coal on private docks of industrial consumers, which is included in consumers' supply.

The quantity of unbilled coal in cars at the mines increased from 73,000 tons on Jan. 1 to approximately 165,000 tons on Feb. 1. Thus it is seen that the coal already mined and awaiting purchasers no longer forms an appreciable part of the reserve.

The accumulation of cars at gateways and terminals increased in January, but the quantity at such points—65,000 tons—was much smaller than during the period of acute traffic congestion following the miners' strike during the past summer.

Reports from an incomplete list of producers equipped to store show that 730,000 tons were in storage on Feb. 1 at the mines, against 770,000 tons held by the same producers on Jan. 1. The number of producers who store is small, but the quantity in storage at times may be considerable.

Reports received from 20 byproduct coke plants stated that the quantity now on hand from day to day represents merely a normal working supply. On Feb. 1, 1923, these plants had on hand 145,839 tons of coke. On Jan. 1 the same plants had 212,261 tons and on March 1, 1922, when the accumulation was largest, the quantity of unsold coke was 870,000 tons. A large part of the surplus found its way to householders as a substitute for anthracite.

Owing to the large deficit in anthracite production in 1922, caused by the 23-weeks miners' strike, consumers of this fuel have turned to bituminous coal as a substitute. It is necessary therefore to reckon the supply of the retailers in anthracite-consuming territory in terms of anthracite and bituminous combined.

There are no available statistics on householders' stocks but in view of the fact that householders had but little opportunity to lay in supplies during the summer and that shipments since September have been on the basis of 60 per cent of shipments in 1921, it seems highly improbable that householders now have any considerable supply.

January deliveries of anthracite by retailers exceeded receipts and stocks declined to the lowest point on record, excepting only Sept. 1 and Oct. 1, 1922. Stocks in the yards of 371 dealers were nearly 13 per cent less on Feb. 1, 1923, than on Jan. 1, and they were a bare third and even a quarter of those during preceding winter seasons. On the average retailers' stocks of anthracite were sufficient to last 8 days, whereas the supply on March 1, 1920, a month later in the season, were sufficient for 21 days, and on March 1, 1922, for 28 days.

The production of anthracite continued at a high rate during February, but severe winter weather has prevailed in the anthracite consuming area, and it hardly seems probable that the reserve is now any larger than on Feb. 1.

DAY'S SUPPLY OF BITUMINOUS COAL IN HANDS OF VARIOUS CLASSES OF CONSUMERS IN THE UNITED STATES, NOVEMBER, 1918, TO FEB. 1, 1923 (*a*)

(Figures represent number of days supply would last at current rate of consumption at time of stock-taking)

	Nov. 11, 1918	Jan. 1, 1919	Mar. 1, 1920	Jan. 1, 1921	Apr. 1, 1921	Jan. 1, 1922	Mar. 1, 1922	Sept. 1, 1922	Oct. 1, 1922	Nov. 1, 1922	Jan. 1 (*b*) 1923	Feb. 1 (*b*) 1923

Total bituminous	45	42	18	39	36	41	43	17*c*	21*c*	23*c*	26*c*	24*c*

(*a*) The figures in this table are estimates based on incomplete data. (*b*) See text for rate consumption at which these figures were calculated. (*c*) Subject to revision.

ANTHRACITE IN YARDS OF A SELECTED LIST OF RETAIL COAL DEALERS (*a*)

Date	Net Tons	Days' Supply (*b*)	Date	Net Tons	Days' Supply (*b*)
1919—Jan. 1	902,950	36	1922—Sept. 1	138,399	5*c*
Apr. 1	846,731	31	Oct. 1	276,480	7*c*
1920—Mar. 1	709,552	21	Nov. 1	448.944	11
1921—Jan. 1	687,851	24	1923—Jan. 1	402,407	11
1922—Jan. 1	1,295,806	44	Feb. 1	351,083	8
Mar. 1	1,075,319	28			

(*a*) Based on statements from 371 identical dealers who reported on each date. (*b*) Calculated at current rate of delivery to consumers, which varies. (*c*) Calculated at rate of delivery in September, 1921.

According to the reports received from retailers the rate of delivery of bituminous coal in the anthracite consuming territory during January was 20 per cent larger than in November and December, 1922, during which period such deliveries were 40 per cent larger than in the corresponding period of 1921. This may be accepted as a broad measure of the extent to which bituminous coal has been used to fill the gap in anthracite production.

Despite the substitution of bituminous coal for anthracite, total stocks of all coal, anthracite and bituminous, in the

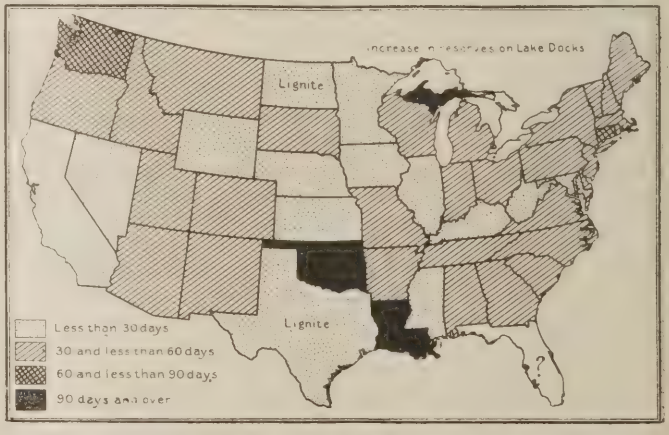

FIG. 3—DAYS' SUPPLY OF SOFT COAL ON HAND AT INDUSTRIAL PLANTS ON FEB. 1, 1923

At the rate of consumption prevailing in January, stocks at industrial plants other than steel and byproduct coke would last on the average 36 days. How the supply varied from state to state is shown in the diagram. The darker the shading the heavier were the stocks. Any change in business activity affecting coal consumption would be reflected in the days' supply. Based on reports from 2,172 plants.

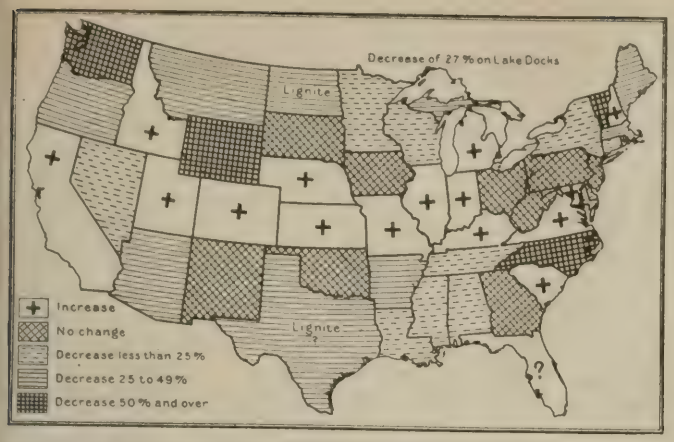

FIG. 4—HOW RETAILERS' STOCKS OF ALL COAL, ANTHRACITE AND BITUMINOUS, ON FEB. 1, 1923, COMPARED WITH THOSE ON JAN. 1, 1923

Stocks of bituminous coal in retail yards on Feb. 1 were 3 per cent less than on Jan. 1. Stocks of anthracite were 13 per cent less than on New Year's Day. The total stocks of retailers, including both hard and soft coal, decreased 6 per cent during January. The map shows the decline to have been most severe in the North Atlantic states, the Northwest territory served from the Lake docks, and in the South and Southwest. In the belt of states from Virginia and the Southern Peninsula of Michigan to Utah stocks in the hands of retailers increased.

retail yards of the anthracite territory was considerably below normal. On Jan. 1, 1923, the total reserve supply was nearly 50 per cent less than on Jan. 1, 1922. Stocks continued to decline in January, and on Feb. 1 the total coal held by retailers was nearly 7 per cent less than on Jan. 1, 1923. Over the country as a whole, retailers' total stocks were 6 per cent less on Feb. 1 than on Jan. 1. From the map in Fig. 4 it is seen that stocks declined in nearly every state in the anthracite-consuming territory. The most notable exception was the Southern Peninsula of Michigan, where increased receipts of bituminous coal were responsible for a 9 per cent increase in total stocks.

Stocks of anthracite on the Upper Lake Docks, as reported by the Northwestern Coal Dock Operators' Association, stood at 57,636 tons on Feb. 1, against 177,644 tons on Jan. 1, 1923. Stocks of anthracite on the Lake docks were less than 6 per cent of those on Feb. 1 a year ago.

Jan. 1, 1922	1,331,507	Jan. 1, 1923	177,644
Feb. 1, 1922	1,030,170	Feb. 1, 1923	57,636

Lack of complete information makes it impossible to state the quantity of coal in the storage yards of producers. The demand has been such, however, that it seems improbable that any considerable quantity was added to stocks, in which event the quantity was practically negligible.

Permanent Injunction in Maynard Case May Have Far-Reaching Effect

The entire coal industry of the United States may be affected by the decision handed down by Justice Bailey, in the Supreme Court in the District of Columbia, making permanent an injunction restraining the Federal Trade Commission from requiring the Maynard Coal Co., of Columbus, Ohio, to submit monthly reports on the cost of coal production. The case had been pending in the court for three years. A temporary injunction was first granted.

The suit was brought by the National Coal Association, using the name of the Maynard Coal Co., according to George H. Barker, vice-president of the company. Mr. Barker stated that the action was filed on the ground that information sought was a duplication of reports submitted to other government departments, one of them the Treasury Department, and that to file reports on special blanks required by the Trade Commission would involve unnecessary expense in the accounting division of every coal company in the country.

Mr. Barker stated that he was unable to say whether Justice Bailey, in his decision, would relieve all other coal companies from the necessity of submitting monthly reports.

Heavy Premium Paid in Massachusetts for "Independent" Anthracite, Report Says

Retail coal dealers in Massachusetts paid over $800,000 premiums in excess of "company" prices for anthracite during the period between Oct. 1, 1922, and Jan. 1, 1923, declares a report of the Special Commission on Necessaries of Life filed with the Legislature of that state.

The commission makes public a list of Massachusetts jobbers and outside jobbers who, it asserts, charged more than $9.50 per ton for coal. Massachusetts jobbers, the report shows, sold to the retail dealers of the state 154,491 tons of coal at prices ranging from $9.65 to $14.50 per ton while outside jobbers sold 85,390 tons at prices ranging from $10 to $14.50 per ton.

Declaring that "there was considerable criticism" when the Federal Fuel Administration during the war allowed all "independent" producers a maximum premium of 75c. a ton over the price of "company" coal, its purpose being to stimulate production, the commission in its report says: "In the present emergency the premium on spot 'independent' coal is as high as $6.25 a ton over the price of 'company' coal."

Some jobbers informed the commission that they handled only a few cars of the high-priced coal as an accommodation to regular customers. Some stated that their margin of profit was only 25c. per ton, while others made no qualifying statement in regard to their dealings.

Commenting on the plan of distribution the commission's report says: "Under the prevailing system of the Pennsylvania Fuel Commission for distributing anthracite this large amount of high-priced coal has reduced the allotment to Massachusetts of a larger amount of lower-priced coal. There is no apparent shortage of this high-priced coal. Undoubtedly our retail dealers intended by purchasing this coal to increase the amount of coal received by their communities. Their action, however, apparently has resulted in raising the price of speculative coal and thus the price our householders must pay."

Arista Disaster Laid to Blown-out Shot

The coroner's jury investigating the explosion on Friday, March 2, at the Arista mine of the Weyanoke Coal & Coke Co., in Mercer County, West Virginia, in which ten lost their lives and twenty-eight others were injured, found that it was due to a blown-out shot, unlawfully loaded, unlawfully tamped or not tamped at all, in the working place of James B. McCloud, who was among those killed. There were no eye-witnesses at the inquest, as all the men in the immediate vicinity of where the explosion had occurred were killed, and hence the mine department had only supposition upon which to proceed. The hole in the working place of McCloud which caused the explosion and three sticks of dynamite found in McCloud's powder box were a part of the evidence upon which witnesses based their testimony. The opinion entertained by mine inspectors, as told to the coroner's jury, was that the dynamite had exploded first, shaking the walls of the mine and raising the dust, and that the powder had then become ignited, blowing out the drillhole and setting fire to the dust.

Fuel Situation Improved in Northeast; To Report Stocks April 1 and June 1

Federal Fuel Distributor Wadleigh reported on March 11 that there has been some improvement in the fuel situation in New England and northern New York. Largely due to motive power trouble, there still is room for great improvement in the railway service. Difficulties continue in New England harbors and a number of applications for service orders intended to give priority to the discharge of coal cargoes have been filed. Mr. Wadleigh stated that it is the present plan to issue another stock report on April 1 and still another on June 1.

E. J. Gealy Joins Staff of Coal Age

E. J. Gealy, recently assistant electrical engineer for the Lehigh Valley Coal Co. and supervisor of the Wilkes-Barre branch of the Pennsylvania State College Extension School, has joined the editorial staff of *Coal Age*.

Mr. Gealy was born in Scranton and is a graduate of Pennsylvania State College, where he studied electrical engineering with respect to its application to the coal-mining industry, receiving the degree of B. S. on graduation.

Following his graduation Mr. Gealy was employed by the D., L. & W., now the Glen Alden Coal Co., of Scranton. Several years later he received an advanced degree in electrical engineering covered by a thesis on "The Alternating-Current Induction Motor as Applied to Mine Hoists."

Within the past five years Mr. Gealy has been a teacher on the staff of the Y. M. C. A. Mining Institute at Wilkes-Barre as well as the Pennsylvania State College Engineering School, of which he has been supervisor for the past three years. Six years ago he entered the employ of Lehigh Valley Coal Co., where his work covered every phase of electrical mining development, including layouts, construction and maintenance for haulage systems, locomotives, hoists, pumps, fans, substations, power plans, power lines, breaker drives, washery drives and compressor drives.

Mr. Gealy also had charge of the layout of the first automatic substation in the anthracite field, located at Drifton.

I. R. T. Asks Approval on Bids for Coal On Basis of $3.89 per Net Ton at Mine

The Interborough Rapid Transit Co., New York City, will get its coal supply for this year on a base price of $7.50 per gross ton at the power houses, or a mine price of about $3.89 per net ton at the mines, if the Transit Commission of New York approves of the proposed agreement.

The contract provides that the 800,000 gross tons to be furnished by the companies to whom it is apportioned shall be Pennsylvania low-volatile bituminous coal, navy standard, as heretofore supplied. Of the tonnage the Berwind-White Coal Mining Co. is to furnish 444,000 tons; Consolidation Coal Co., 296,000 tons and the Logan Coal Co., a Philadelphia organization with mines at Dunlo, Pa., 60,000 tons.

The proposed contract contains a sliding-scale provision for any increase or decrease in freight rates or miners' pay and the contractors also agree to give the transit company the benefit of lower prices if they make contracts for coal of the same grade at lower prices to other consumers at New York harbor, or if they sell without contracts any such coal at lower prices they agree to furnish the transit company with an equal amount under contracts at such prices.

The committee of the Board of Directors of the Interborough Rapid Transit Co. that drew up the contract believes that these provisions, "which are unusual in contracts of this kind, insure a lower cost per heat unit than could be obtained by any other method, in view of existing conditions."

Referring to the investigation recently made by a committee representing New York City, of which David Hirshfield, Commissioner of Accounts, was chairman, into conditions at the mines of the Berwind-White Coal Mining Co. the committee's report says:

"We have not overlooked certain matters relating to labor disputes and alleged mining conditions at the Berwind-White mines. We have looked into these matters not only in the interest of the Interborough company but out of courtesy to the city administration, which has given attention to the subject. We are not able, however, to convince ourselves that these matters should be permitted to swerve our business judgment as to what is best for the public, the city and our own company. All things considered, we believe that we have taken the only prudent course open to us in the circumstances."

The committee says that during the coming year it will give consideration to the use of oil for fuel and also to the acquisition of storage facilities and additional equipment, so that, if deemed advisable, coal may be purchased in open competition.

The committee that drew up the proposed contract, after considerable study of the fuel situation, was composed of Abel E. Blackmar, former Chief Justice of the Appellate Division, Supreme Court, Second Department, Kings County, who represents the public on the Board of Directors; Thomas I. Parkinson, vice-president of the Equitable Life Assurance Co., and Samuel W. Reyburn, of Lord & Taylor. Before it is accepted by the Interborough Co. the contract must be passed upon by the Transit Commission.

Second Herrin Trial Reviews Massacre; More Politics in the Case

The second Herrin trial now progressing at Marion, Ill., has developed little evidence concerning the slaughter of 22 non-union strip miners near Herrin, Ill., last June that was not brought out in the first trial which ended six weeks ago in acquittal for the prisoners—union miners in a solidly unionized community. Hugh Willis, union board member and one of the five defendants charged with the murder of a Polish guard at the besieged strip mine of the Southern Illinois Coal Co., has again and again been charged by witnesses with inciting the mob to the slaughter after the non-union men had surrendered to the mob. The bloody details of the killing have been reviewed in various ways and the testimony of state's witnesses plods steadily along while the Williamson County populace pays little attention to the case and none of the observers feels that a conviction is possible.

Some of the witnesses for the state, who testified clearly and damningly against the mine-union defendants at the first trial, have been put back on the stand during the past week, but too often they have "forgotten" so much about the case that their evidence has not been weighty and the prosecutors have dismissed them with disgust.

While the trial droned along the state appropriation of $75,000 to finance the prosecution, which passed the Legislature late in February, had to be rescued from the dust at the bottom of a drawer in Governor Small's desk. Somebody pointed out in a Senate session that the Governor's allotted ten days to sign or return the bill had elapsed, that nothing had happened and that the bill might die from inaction. So a committee waited to His Excellency.

"Do you mind if we take this bill to the Secretary of State now that you have decided not to sign it?" asked the chairman of the committee.

"I don't care anything about it," said the Governor. "Take it along."

So they took it along, while a Senator remarked that he was informed by old-time state officials that never before had a Governor proceeded in such a manner regarding a bill.

Assured of Funds to Complete Its Investigation, Coal Commission Speeds Up Work

By Paul Wooton
Washington Correspondent of *Coal Age*

With the removal of uncertainty with regard to its appropriation and in fact its very existence, the President's Coal Commission is bustling with increased activity. The statistical force has been expanded and tabulation of information contained on the questionnaires has been speeded up decidedly. During the week ended March 10 a material increase in the rate of tabulation was achieved. The returns also are coming in in greater numbers.

A large number of the questionnaires were filled out prior to the enactment of the law providing special penalties for false returns. It is probable that the commission will send out some form of statement to be signed by the persons making those returns which will certify that the questionnaire is resubmitted as correct. This action will not be taken with any idea that incorrect returns have been made but on the belief that the conclusions of the commission will have more weight with the public if it is known that they are based on sworn statements. As a matter of fact, it is probable that the original act fixed full legal responsibility for the correctness of returns. Certainly were the commission to entertain any doubt as to the correctness of any return, it could have compelled verification, even if it were necessary to bring all the books of the company to Washington. In that connection, however, Commissioner Smith points out that the club provided was too big to use.

New questionnaires now are being prepared to cover certain phases of distribution. The American Wholesale Coal Association and the Retail Coal Merchants Association are being consulted in connection with the preparation of these schedules.

The field investigations in connection with wholesale and retail practices in the larger cities are now being completed. The work is practically complete in Buffalo, Chicago, Columbus, Detroit, Indianapolis, St. Louis, Minneapolis and St. Paul. The survey of the Northwest docks also is practically complete.

Commissioner Smith announced on March 10 that C. E. Lesher, who is in charge of the engineering phases of the commission's investigation, is strengthening his force and will speed up that important part of the fact finding. Through an arrangement with the Bureau of Mines, George T. Halderman has been added to the engineering staff. Mr. Halderman is a coal-mining engineer with diplomas from Pennsylvania State College and the University of Pittsburgh. Prior to accepting service with the Bureau of Mines he was employed by the Lehigh Valley Coal Co., the Peabody Coal Co., the Colorado-Utah Coal Co. and other producers.

When Commissioner Smith was informed that all of the retailers were not prepared to "swallow" the commission's plan for encouraging storage during the summer of domestic fuel, he remarked that such plans as that proposed by the Connecticut company and the modifications of that plan likely to be adopted by other large employers could be made unnecessary were retail dealers willing to work out some plan of their own to stimulate summer storage of household fuel. It is understood that the Retail Coal Merchants Association will call a meeting in the near future to consider the whole subject of storage.

The commission cannot be accused of setting the scene for its report, Dr. Smith pointed out, since, by doing all in its power to encourage storage and to prevent any shortage next autumn, a situation has been created whereby the public will not be concerned about coal at the time the commission's report will be issued. It can clearly be foreseen that Sept. 22 will not be a highly propitious time to obtain for the report the maximum amount of public attention. Nevertheless Dr. Smith believes that there has been a widespread absorption of knowledge concerning coal during the past few years.

It is the plan of the commission to make available to the conferees on anthracite wage scales all information that will be of service to them at the earliest possible time.

Dr. Smith spent most of the week of March 5 in New York and Philadelphia, where he conferred with a number of persons interested in the coal investigation.

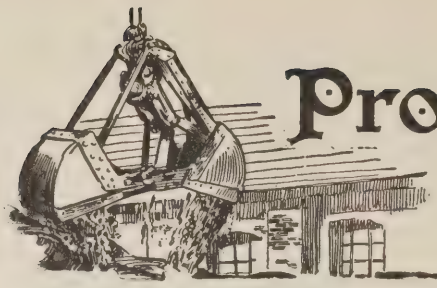
Washington Mines May All Be Open Shop

A request for a reduction of $1.50 in the day-wage scale of union coal miners in Washington State having been refused at a joint conference at Seattle, March 5, and adjournment taken *sine die*, indications point to the five remaining union companies going on an open-shop basis.

The present situation in the Washington coal-mining district began to develop with the refusal of the international union to authorize the Allport commission recommendations determined under instructions by the Bituminous Coal Commission award of March 10, 1920, and concurred in by John P. White, minority member of the commission. This award provided approximately 14 per cent above the 1919 scale award, but it was nevertheless repudiated and a demand made for an advance of $1.50 in the day-wage scale, effective Aug. 16, 1920.

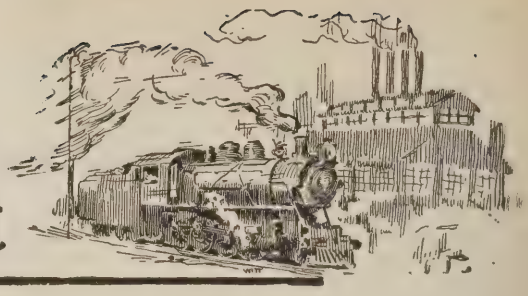
This increase was paid until March, 1921, commercial mines continuing to operate on account of the urgent necessity for railway fuel, but then the State Director of Labor and Industries, to break the deadlock, reconvened the Allport commission and a modified scale was indorsed by the state union. Official concurrence by the international union was again withheld, and as result all but five companies became open shop on the basis of the Allport rates, the five remaining companies, including railroad mines, seeking continuation of relations with the union until the U. S. Coal Commission could determine the facts and make recommendations.

M. H. Taylor, of Pittsburgh Coal Co., Dies



Matthew H. Taylor, chairman of the Board of Directors of the Pittsburgh Coal Co. since 1907, died in Atlantic City on March 7. He was 75 years old. Mr. Taylor was born in Huntingdon, Pa., a son of Judge Taylor. Early in life he moved to Erie, Pa., where he became identified with the W. L. Scott coal interests and at the time of his death was a trustee of the W. L. Scott estate.

Besides being chairman of the Board of Directors of the Pittsburgh Coal Co. Mr. Taylor was vice-president of the Erie & Pittsburgh Railroad Co., president of the Montour Railroad Co. and a director of the Second National Bank of Erie.



Industrial Activity Pronounced in January

Late figures on January business conditions, according to the survey of current business, reprinted from Commerce Reports, continue to show pronounced activity throughout the industries. Although the building-material industry shows the most activity, there has been a noticeable advance in activity in almost all lines, with production figures close to or exceeding the 1920 peaks. Additional high production records since early in 1920 were made in January by copper, glass bottles, clay fire brick, silica brick, and enamel sanitary ware.

The cost of living figures show a slight decline in spite of the rising tendency of wholesale prices. Prices received by farmers for crops and live stock also advanced, notwithstanding declines in wholesale prices of agricultural products.

Production and the Market

Weekly Review

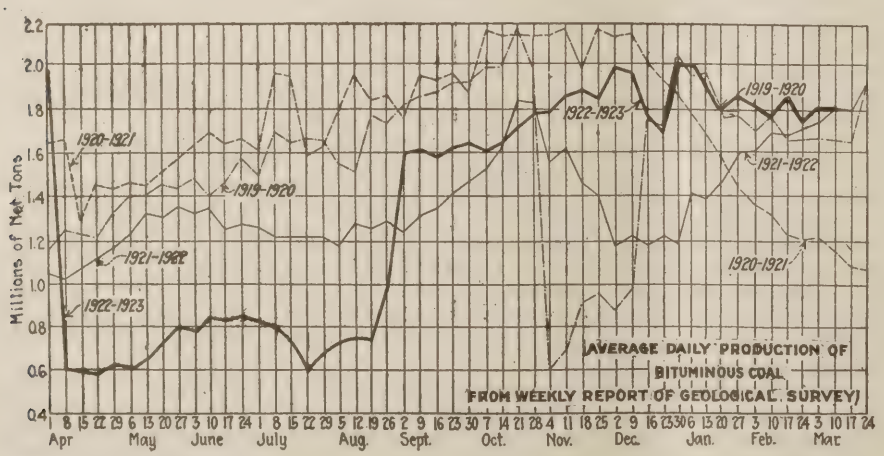
No surprise was occasioned in the coal trade by the government stock report, issued late last week, showing a gain during January of 2,000,000 tons of soft coal in the hands of consumers, thus indicating a total of 38,000,000 tons on Feb. 1. It is conceded that almost an equal amount was lost during February, for consumption was at a higher rate than in January and production at a lower rate. February output of soft coal was 42,130,000 tons, a drop of 16 per cent in average daily production. Consumption and exports during January are estimated by the government at 10,700,000 tons per week.

Demand for soft coal in the East is fast being relieved of retail-dealer orders, a fact partly accounting for the softness of the market. *Coal Age* Index of spot prices of bituminous coal at the mines dropped 11 points to 268 on March 12, the corresponding average price being $3.24.

Export Demand Strong

The only feature of the week is the gradual development of export demand. Interest, of course, lies in the inquiries for Germany, France, and other continental European countries. Some orders have been closed and vessels have been chartered. The immediate effect has been a gain in movement to the West Indies and other nearby offshore markets. A sharp demand last week advanced Pocahontas at Hampton Roads by $1 per ton and high-volatile Kanawha gas coals were up to $6@ $6.25 f.o.b. Hampton Roads on March 10. Altogether it was estimated that upward of 250,000 tons of coal had been engaged for shipment to foreign countries and that 25 vessels had been chartered.

In the Midwest the domestic market has been affected by the season. The volume of domestic coals has fallen off, with indications of a further slump in prices. There is enough coal in the Northwest to keep the market calm on almost every kind of coal. Industrial conditions have improved sufficiently around the upper Lakes to move considerable coal off the docks, leaving little except fuel under contract. Of the 1,200,000 tons on the Duluth-Superior docks, most of it is screenings. Quotations for southern Illinois and Standard coals remained on about the same basis, while nearly every other grade, excepting Pocahontas and New River took a drop.



Eastern Situation Quiet

In the East there is less complaint about car shortage, which has not changed materially from last week. Coal stocks are equal to requirements and consumers in some sections appear to be eating into their reserve supplies. In New England manufacturers are endeavoring to maintain their 60- and 90-day reserves. There is a better outlook for manufactured goods and mill buyers show more interest in the market. The demand for Southern coals from abroad had a tendency to increase the activity of large consumers. At various terminals there was some delay in discharging boats.

Present estimates of soft-coal production in the week ended March 3, according to the Geological Survey, indicate a total output of 10,860,000 net tons, including coal shipped, mine fuel, local sales, and coal coked. This is an increase of more than one-half million tons over the revised estimate of 10,323,000 tons for the week preceding.

Preliminary reports of cars loaded in the week of March 5-10 show 42,194 cars loaded on Monday, a decrease to 33,181 cars on Tuesday and to 28,296 cars on Thursday. Loadings for the first four days of the week were slightly below those for the corresponding days of the preceding week. The total output probably will be between 10,750,000 and 10,850,000 tons.

The anthracite situation continues active. Domestic

sizes are moving steadily, but there has been less demand for the product of the small independent operators, with the result that their quotations have dropped. Steam coals are easier and quotations also are easier.

The movement in contracting for Connellsville furnace coke for the second quarter is now nearly completed. The great bulk was done at $7 but three or four of the latest contracts were at $7.25, the operators holding out for that price on account of quality and service. Car service in the region has been practically adequate for the past thirty days.

Midwestern Steam Market Firmer

It is obvious to most coal producers and sales companies in the Midwest that the domestic market is flat for the season. The volume of domestic coals from all fields has fallen off steadily and swiftly during the last ten days and efforts to hold circular prices in line cannot be effectual much longer. The dealer trade is determined that lump, egg and nut prices must drop lower at once. The result of all this is that the high-cost mines are beginning to shut down and the volume of coal produced has fallen to such an extent that screenings are giving just enough evidence of shortness so that the prices on them are firming a little at last. Southern Illinois screenings, which have sold down to $2.25 as a regular thing, have risen until $2.50 is more nearly an average. Central Illinois screenings have inched upward from $1.15@$1.25 nearly to $1.50, leaving only Standard district screenings unchanged from the week before. The principal reason for this is that Standard domestic sizes have been selling more steadily as they are the cheapest fuel in Illinois.

Southern Illinois field conditions are not happy. No-bills are piling up there, as they have been in all other Illinois regions for weeks. Railroad tonnage is light. Most roads have been entirely satisfied with their minimum contract quantities. Unfilled orders are now largely a thing of the past, for car supply has grown better and almost any mine that wants to run can easily get 60 jer cent of its rating, if not more. Shutdowns are the result.

Kentucky Prices Breaking

In Kentucky mild weather has cut down demand for domestic fuel, and as a result of there being some distress transit coal on some of the markets, there probably is no coal

* Net tons, f.o.b. mines † Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 268, Week of March 12, 1923. Average spot price for same period $3.24. This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

now shipping on consignment. Prices are weaker all along the line, and lump broke under $3 last week for the first time in months, while mine-run is quoted under $2. Car allotments show larger on a percentage basis as a result of railroads cutting back to June 10 and adding 10 per cent to the May loading records in alloting cars. However, for the first time in months there was a little surplus of cars on the Illinois Central lines in western Kentucky on Monday as a result of idleness on Sunday. For the month, as far as railroads have reported, the Illinois Central shows 46 per cent of cars supplied, while the Owensboro division of the L. & N. is improving with 33 per cent and the Henderson division shows 28 per cent.

Operators acknowledge that the outlook is not promising in view of the fact that no early movement in a big way is anticipated north.

Market Sags in Northwest, Too

About the only shortage that causes even a ripple in the Northwest is the lack of coke for local use in Milwaukee. While docks in that city are scraped clean, car-ferry deliveries have improved a little. During February 23,605 tons of anthracite arrived and 62,383 tons of bituminous. By rail there arrived a little anthracite and 79,184 tons of soft coal. Interior dealers, who have been ordering broadcast and getting nothing, are not worrying much any more. Lake traffic may open up within six weeks.

The dock men are now deeply engrossed in the campaign of showing the country they cannot continue to do business unless the Interstate Commerce Commission alters rates so as to give the docks a better shake as against all-rail coal from Illinois and Indiana.

Stormy weather and some industrial activity, which have held up the market for Utah coal, are no longer effective. Mines throughout the state are shutting down. A railroad ruling that no mine shall get cars so long as it has as many as 50 per cent no-bills on hand is indicative of the situation. The mild weather is having exactly the same effect in Colorado. Fully 50 per cent of the coal operations of the state are down just now. Circulars issued in Kansas City March 8 show a 50c. break on both Kansas lump and nut and on Arkansas lump and mine run.

Ohio Hears of Smokeless Price Cut

In Ohio steel interests are inclined to talk about contracts. Demand for smokeless slack coals have picked up. Reports have it that smokeless operators are going to reduce prices on April 1. The movement for high-volatile coals has stiffened both in price and in the tone of the market. The railways have cleaned up considerably and the movement through the gateway is much better.

While steam grades are holding fairly well in the Columbus market there was a slump in domestic sizes, due largely to higher temperatures and the fact that dealers are moving slowly in placing orders. Retail prices have weakened a little because of weather conditions. Buying of both mine-run and screenings is more active and there is little free coal of those varieties on the market. With car supply reduced to about 15 to 20 per cent of capacity, steam grades are not as plentiful as formerly. Railroads with their assigned cars are taking a large part of the steam production in certain districts. Embargoes are affecting sections of Michigan and Indiana as well as some parts of Ohio.

Eastern Ohio mines are operating at a little less than 40 per cent of capacity, due to car shortage and transportation difficulties. During the week ended March 3, these mines produced 305,000 tons of coal, or 52,000 tons more than during the previous week, which however, consisted of only five work days. Manufacturers stocks are small but there are no indications any difficulty will be experienced by this class of consumer in getting his coal as needed.

Car shortage throughout West Virginia is very pronounced. There was a slight increase in production in the Pocahontas and Tug River districts, as congestion in some sections was relieved. Smokeless coal is on a firmer basis as a result of export inquiries. Quotations for mine-run ranged from $3.75 to $4.25 per ton.

Producers of high-volatile coals in West Virginia are feeling more optimistic as a result of increased industrial activity in the Eastern market and look forward to further improvement.

In the Pittsburgh district car supply is hardly any better, but there is less complaint, operators finding that production is equal to requirements. There is no demand for domestic coal except from the territory normally tributary to the district. Consumption by public service companies, manufacturers and the steel industry is heavy.

Production in the Birmingham (Ala.) district is being maintained around 385,000 tons weekly and there has been an improvement in car supply. Bunker trade at the Gulf ports has been somewhat better and some coal has been exported to Cuba. There has been a falling off in demand for domestic coals due to warmer weather.

The demand for soft coal in Buffalo is quiet.

New England Market Takes Turn for Better

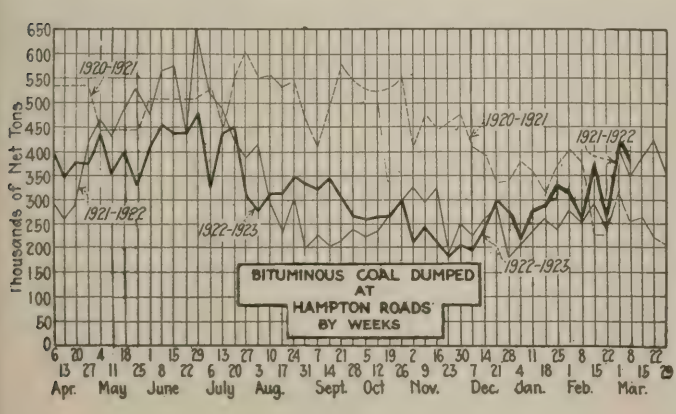
With practically no advance indications the soft coal market in New England took a turn for the better something more than a week ago. Influenced partly by continuing embargoes all-rail and by a somewhat better outlook for manufactured goods mill buyers have shown more interest in current quotations. There has developed a disposition to hedge on the course of the spring market and it is probable that the remainder of March will show heavier purchases than were expected.

Both Italian and English orders have materialized within

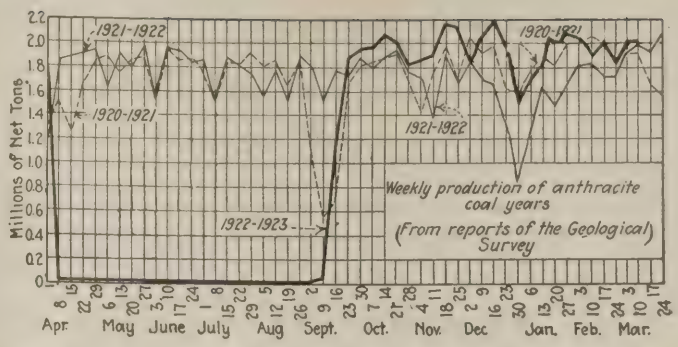
a week's time, and while there is a tendency to exaggerate the tonnage required it is a fact that cargoes are not only in process but steamers have already made their departure for Mediterranean ports. So recent is this feature that ships are passing each other on the high seas, some of them bound this way with English coal on commitments of thirty days ago while others are outward bound with American coal destined to British agents. This new foreign demand is particularly difficult to gage because inquiries find their way to so many brokers and tonnages are often multiplied tenfold.

To all this promise of spot business the Southern smokeless coals have reacted sharply. Medium to second-grade low-volatile that were a drug a few days ago at $6@$6.25 have sold within a day or two up to $7, while navy standard coals have risen to $7.25 per gross ton f.o.b. vessel.

At Providence, Boston and Portland rehandlers are in more or less distress over terminal delays. At Portland cargoes are being detained ten days or so awaiting berth, while at Boston and Providence there are instances where boats will not be discharged before the first week in April. Some of the congestion is due to railroad fuel from Welsh ports, but perhaps the bulk of the coal awaiting disposition results from the attempts of some of the agencies to force shipments on reluctant buyers. Where a fortnight or so ago there were reasonably large accumulations at Hampton Roads daily receipts are now being absorbed with little or no delay. If car-supply can be improved on the Virginia railroads there probably is little doubt now that a materially increased output can be taken care of.



All-rail inquiry also has shown an improvement, although there has been no appreciable change in prices. In fact spot coal from central Pennsylvania was sold at a lower range than applied on December purchases for deliveries extended through February. The permit system is in use on the three chief New England carriers, especially on coal originating on the New York Central, but authority to ship is not difficult to obtain where moderate tonnages are involved, and the trade expects the gateway situation to improve measureably by April 1. Meanwhile many shippers are continuing their active canvass for contract business. Apparently they believe that taking the season as a whole it will be to their advantage to close a large proportion of anticipated output about on the basis of present spot prices. By the same logic the larger consumers here are less inclined to make contracts than to buy moderately in the present market.



Market at New York Still Quiet

The New York market continues quiet, but most operators are optimistic. The better grades are sold up. Local houses are receiving many inquiries for foreign shipments for coal as well as for coke.

Conditions in the Philadelphia market show no change. Most consumers are buying to meet current requirements, but with active industrial conditions the actual consumption of coal is increasing.

There has been a gradual resumption of export movement at Baltimore. One steamer leaving Baltimore with 5,677 tons of Fairmont coal for Leghorn, Italy, had discharged Welsh coal at Boston. Another vessel that brought coal to Providence will load coal for Italy at the Western Maryland docks. There was a gradual growth in demand for bunker coal, with quotations for Pool 9 around $6.45 at the piers.

Domestic Anthracite Finds Ready Market

Domestic sizes of anthracite are finding a ready market. Consumers in New York territory are placing orders for next winter's supply and are telling their dealers to put the coal into their bins as soon as possible. Producers do not look for any let-up in demand this spring and summer, at least not until most consumers have put in their coal. Similar conditions exist in Philadelphia. In Baltimore, where dealers have not been able to deliver all of their orders, some consumers have cancelled parts of their orders, having sufficient deliveries to last them the balance of the season. Orders are being cut from various parts of the country. Some coal has been refused by dealers from Canada unless it is of high quality.

The production of anthracite in the week ended March 3, according to the Geological Survey, increased notably over the production in the week before and is estimated at 2,104,000 net tons, including coal shipped, mine fuel, local sales and dredge and washery output.

Early returns on car loadings during the first four days of the week March 5-10 indicate somewhat lower rate of production and a probable total output for the week of approximately 2,000,000 tons.

Foreign Market And Export News

Demand for Welsh Coal for Export Increases; Production Shows Slight Decrease

There was a further drop in British coal production during the week ended Feb. 24, according to a cable received by *Coal Age*. The output amounted to 5,519,000 tons, as compared with 5,560,000 tons the previous week. This is the fifth consecutive week in which production has shown a decline.

Demand upon the South Wales operators is increasing and they are heavily booked for March and April deliveries. It is reported that the German State Railways are inviting offers of any quantity of Northumberland and Durham coals for delivery at stated periods throughout the year.

There was a heavy demand for coke and coking smalls from Germany, as well as from France, Italy and Belgium.

The negotiations for the three-shift day at the docks have been broken off and the coal exporters, dock owners and others interested have asked the Industrial Court to make an inquiry.

German buyers are buying heavily in the North of England market, at prices quoted for late March and April delivery. Belgium, France and Italy also are making inquiries.

Within the past few weeks there have been strikes in various parts of South Wales over the non-unionist question, affecting several thousand men in the aggregate.

Hampton Roads Market Brisk

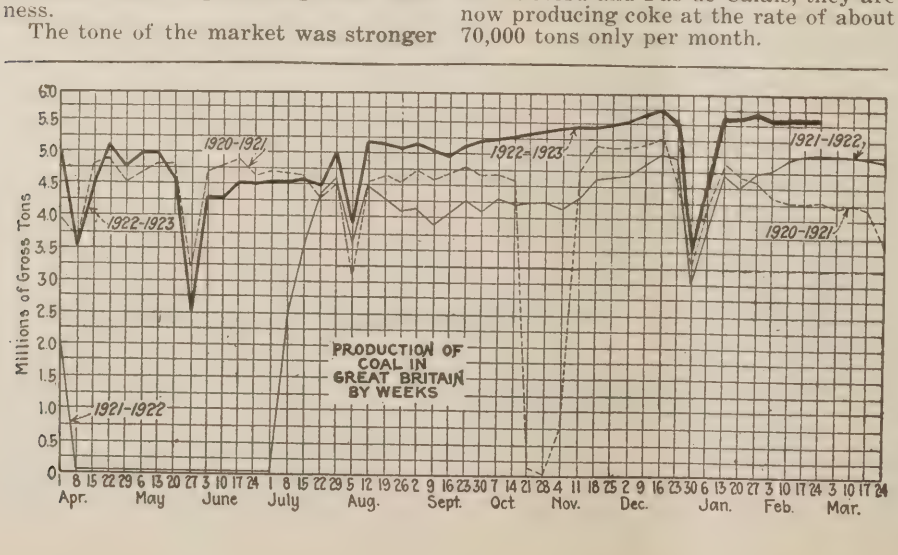
Business was more brisk at Hampton Roads, with prices stiffening and with a considerable volume of coal for export moving for the first time in many months. One steamer loaded coal for Germany.

Coastwise business was better, also, and supplies at the piers were being cut down materially. The eyes of the trade turned to the export field, speculating on the outcome of the German situation which is promising much business.

The tone of the market was stronger than for many weeks, and coal moved on a better schedule from the mines. The general outlook was much brighter and a better feeling throughout the trade resulted.

French Miners Get Wage Increase

Except in Lorraine and in the Saar, where the present agitation is partly due to influences from Berlin, the strikes which broke out on Feb. 16 in various French coal fields are now ended. The miners obtained the following wage increases per shift:



Nord and Pas-de-Calais	3 fr., 25
Loire	3 fr.
Aveyron (Decazeville)	3 fr.
Blanzy colliery	2 fr., 50
Gard	2 fr., 50

On the whole, the wages of French coal miners are brought back to their record level of 1921.

Pending the publication of their new schedules for renewal of annual contracts, the bulk of which start from April 1, collieries of the Nord and Pas-de-Calais have raised by 7 to 10 frs. prices to be applied to isolated orders or to contracts renewed before the end of March.

The interruption of shipments from the Ruhr, as well as the strikes in the Saar and in Lorraine, have taken away from the French market about one million tons per month.

French blast-furnaces, especially those of the East of France, are in a bad way as regards coke supplies. From Feb. 12 to Feb. 20, they received only 6,400 tons of coke from the Ruhr. Shipments of Belgian coke are being suspended pending the conclusion of an agreement relative to exchange shipments of French iron scrap to Belgium. British coke can of course be obtained, but in insufficient supplies and at excessive prices. As to French coke ovens of the Nord and Pas-de-Calais, they are now producing coke at the rate of about 70,000 tons only per month.

News Items From Field and Trade

ALABAMA

The Kewanee Coal Co. at Jasper has been incorporated by W. G. Duffee, J. R. Smith and A. K. Smith.

CALIFORNIA

The Chicago Pneumatic Tool Co., New York, announces the appointment of **H. J. Bradley** as San Francisco branch manager succeeding J. K. Haigh, who has been transferred to the Chicago branch to resume sales work.

COLORADO

The Colorado Fuel & Iron Co. reports for the year ended Dec. 31 last **net earnings of $3,261,327**, compared with $1,773,505 in 1921, and a deficit after depreciation, taxes, etc., of $654,944, against $2,371,171 in the previous year. J. F. Welborn, president, says that the coal strike did not adversely affect business, the average coal production during the strike period being several thousand tons in excess of the monthly average for the year.

CONNECTICUT

Governor Templeton has announced that, immediately following the adjournment of the Legislature, he **will invite the Governors of all the New England states and Pennsylvania to a conference** in Hartford to prepare for a possible repetition of the coal emergency next winter.

ILLINOIS

The Central Illinois Traffic Bureau, with offices in Chicago, is to be continued and **W. H. Holley**, manager for three years until last winter, when he joined the Nason Coal Co. at Chicago, returns to the bureau. **George Hemphill**, who has been temporarily in charge of the bureau, remains in his former capacity as Mr. Holley's right-hand man.

Between 60 and 90 tons of coal is being mined daily from the new Shuler mine near Alpha. There are 13 miners at work in the mine and as soon as the mine is enlarged the force will be increased. The Burlington R.R. has completed the switch to the mine, but the owners of the mine have not laid the track up the mine, so that coal is being transported from the mine by wagon and truck.

Is the Peabody Coal Co. of Chicago going to acquire and operate a section of the old **Chicago, Peoria & St. Louis Ry.?** The report gained circulation late in February when Stuyvesant Peabody, president of the Peabody Coal Co., inspected part of the line with engineers. "Not a word to say," was his only comment after he returned to Chicago. W. C. Hurst, general manager of the railroad said in Springfield that no offer had been made for any part of the road and that this was not the first time the Peabody interests had looked over the property. The railroad company has been petitioning the State Commerce Commission and the I. C. C. for permission to dispose of the line. That part of the railroad from Pekin south and east to Springfield makes junctions with the Illinois Central, Chicago & Alton, Chicago & Northwestern and the Burlington railroads and might be of some value as a coal originating line for a coal company with operations on it. The line now serves five mines jointly with other roads and four mines exclusively. Mr. Peabody denies that his company has bought any more mines on the line. It now operates its No. 51 mine at Andrews on the C. P. & St. L.

Frank W. DeWolf, who has been chief of the Illinois State Geological Survey at the University of Illinois, Urbana, announced his resignation Feb. 28 to engage in commercial work with The Humphreys-Gohs Oil Co., with headquarters at Dallas, Tex. Mr. DeWolf has been with the Illinois State Geological Survey since 1907 and has been in administrative charge since 1909. During this time, the most important investigations carried on by the Survey have dealt with coal and oil possibilities of Illinois. Mr. DeWolf is especially well known in mining circles in Illinois and the Central West.

Consolidation of ownership of the three Franco coal mines in Williamson County, near Marion, with capitalization at $1,500,000 has been announced by R. B. Mitchell, of Marion, vice-president and general manager of the new corporation, known as the Cosgrove Meehan Coal Co., of Illinois. Franco Nos. 1 and 2 were owned by the Ernest Coal Co. and Franco No. 3 by the Sandford Coal Co., both Cosgrove interests centering in Johnstown, Pa.

Reports are that the **Big Four railroad is to build an extension** out of Harrisburg towards West Frankfort, tapping a large section of Franklin County and its many mining centers. It is to be known as the Saline Valley Ry. and acording to reports the right of way has been acquired and work is to be started soon on the project. The proposed extension for a few miles will run parallel to the proposed Illinois Central branch which is now practicailly assured.

Despite adverse working conditions in January the Coal Operators' Association of the Fifth and Ninth Districts of Illinois, embracing 83 mines in the southern part of Illinois, report that the **output that month was greater than either November or December**, the total for the month reaching 1,770,879 tons. In December the tonnage was 1,589,619 and in November the production was 1,404,637 tons. The report for the week ending Feb. 3, shows a slackening of production with 329,297 tons hoisted, or 50,000 tons less than in the preceding week. Time worked dropped from 49 per cent of potential hours to 45 per cent. Hours lost because railroad cars were not available showed a considerable increase, and amounted to a greater number of hours than were actually put in by the miners.

R. B. Starek has been appointed executive vice-president of the **Binkley Coal Co.**, which recently purchased the properties of the W. S. Bogle Coal Co., of Chicago. H. A. Stark, former president and general manager of W. S. Bogle & Co., has been named vice-president and general manager. The company has also taken over the Essanbee Mining Co., of Clinton, Ind. The reorganization gives the Binkley company a total of 5,000 acres of coal land and an estimated output of 8,000 tons a day. W. H. Baker has charge of the Chicago sales, while Mr. Stark is in charge of all mine operations as general superintendent, with offices at Clinton, Ind.

INDIANA

The Love Coal Co. has been organized at Anderson, to mine coal. The company has a capital stock of $50,000 and the directors are Eldra O. Love, E. C. Love and L. B. DeSanctis.

The Penna, a new mine of the Templeton Coal Co., Terre Haute, located on the C. M. & St.. P. R.R., was opened Nov. 27, 1922.

The Eagle, a new mine operated by the Eagle Coal & Mining Co., Terre Haute, located on the C. & E. I. R.R., was opened Aug. 31, 1922.

The City Mine, of the City Coal Co., Jasonville, on the C. M. & St. P. R.R., was opened on Oct. 9, 1922.

More than 4,000 miners in the Terre Haute district went on vacation recently and more than twenty mines located north of that city were idle. The cause, it is said, is that the C. M. & St. P. R.R. did not send a train to the Bardyke mine the day previous, when a breakdown occurred, and no means were provided to return the men to their homes until the regular evening miner trains. In the meantime while the miners punish the railroad by not riding trains, the operators are doing repair work.

Dealers and operators of the Brazil block coal field, officially known as District No. 8, reached an agreement at a meeting recently for a continuance of the present wage contract after April 1. The contract is based on the New York agreement for soft-coal mining, but as the block coal is mined under different conditions, a separate scale is made for the Brazil district, providing a differential in favor of the block coal miners.

The Supreme Court of Indiana has ruled that coal operators need not pay employees twice a month and in cash. Numerous cases where payrolls were stolen were cited in argument against the proposed law.

IOWA

The Independent Coal Co. of Burlington has been incorporated with capital of $10,000 by A. G. Ruge and John McMahon.

KANSAS

Mine No. 11 of the Oberzan Coal Co., Mineral, located in Cherokee County on the M. K. & T. R.R., which was closed Sept. 30, 1921, was reopened in July, 1922.

The Old Smith mine, operated by George Dixon and others, of Mineral, located in Cherokee County, which was closed a number of years ago, was reopened in September, 1922. This was formerly connected with the M. K. & T. Railroad and it is the intention of the new company to re-lay the switch.

Mine No. 20 of the Sheridan Coal Co., Mulberry, located in Crawford County, is now being developed. A railroad switch has not been laid yet, but connections will be made with either the Missouri Pacific or the Kansas City Southern, or both.

Mine No. 3 of the McGrath Coal Co., of Pittsburg, in Crawford County on the Frisco R.R., a new operation, is now being developed.

Mine No. 11 of the Graham Coal Co., Pittsburg, located in Crawford County on the Santa Fe R.R., which was closed on Sept. 30, 1921, reopened Aug. 20, 1922.

KENTUCKY

A group of Luisa capitalists, headed by T. B. Lane and M. F. Conley, have formed the **Coalburg Collieries Co.** with a capital of $20,000, and with headquarters at Lawrence, where coal properties will be developed.

The Red Top Coal Co., of Lexington, has announced that it will establish a plant for the manufacture of smokeless blasting powder and that the new plant will be conducted in conjunction with its coal-mining operations.

The Midland Mining Co., of Tribbey, has announced a program of improvement, including the construction of a new tipple, mining houses and the like.

New coal companies which have filed for incorporation at Louisville are these: **Liberty Coal & Coke Co.** with a capital stock of $50,000, of 500 shares. A. R. Anderson holds 50; R. R. Atkins, 50; M. S. B. Barker, 134; A. G. Stith, 133, and T. H. Helm, 133. Limit of debt, $250,000. **L. N. L. Coal and Mining Co.**, Bell; $25,000; M, D. Bell, E. R. Martin and J. E. Bell, all of Pineville. **White Elkhorn Mining Co.**, Letchner; $25,000; Thomas Fugate and J. W. Craft, Hazard, and H. A. Price, Detroit, Mich.

The Oak Ridge Coal Co. has been incorporated at Louisville, with a capital of $50,000. The incorporators are R. Montgomery and J. L. Morris, both of Louisville, and W. R. Hudspeth, of Greenville.

The Virginia Coal & Coke Corporation, with main offices at Roanoke, Va., has leased acreage in the Elkhorn and Hazard fields of eastern Kentucky, near Whiteburg, which it will develop.

The Blackwell mine of the Blackwell Bros. Coal Co., at Powderly, on the Illinois Central Ry., was reopened on Dec. 20, 1922.

The Pond Creek mine of the Pond Creek Coal Co., Central City, on the Kentucky Midland R.R., was opened on Sept. 15, 1922.

The Nonnel mine of the Kentucky Washed Coal Co., Greenville, a strip mine, located on the Louisville & Nashville R.R., was reopened on Dec. 10, 1922.

The No. 3 mine of the Black Diamond Coal Co., Drakesboro, on the Louisville & Nashville R.R., was opened Sept. 15, 1922.

The Lelia mine of the Liberty Coal Mining Co., at Hillside, on the Illinois Central R.R., was reopened Sept. 1, 1922.

In order to relieve congestion in the Louisville terminals the **Louisville & Nashville R.R. has started work on new yards** at Highland Park, where trackage for 1,000 cars will be installed at once, with plans for later materially enlarging switching facilities. More than a year ago the company purchased 463 acres adjoining the present yards on the south.

Jacob Hetzel, M. F. Patrick and D. Glenn Sublett have incorporated the **Laurel Fork Coal Co.** at Salyersville.

A. B. Culton, of the firm of Culton & Sherwin, mining engineers, Pineville, has been **appointed to head the L. & N. rating commission** with offices in Louisville. For the present he will continue to reside in Pineville. The firm of Culton & Sherwin will continue as heretofore with Mr. Culton in a consulting capacity.

Robert Jameson, Earl Jameson and Beatrice Jameson have incorporated the **Edythe Coal Co.**, at Beattyville, Ky., with a capital stock of $20,000.

The Smothers-Gooch Coal Co., at Pineville, has been organized with the election of the following officers: President and manager, Estill A. Smothers; secretary, treasurer and construction engineer, C. L. Gooch. The company was recently incorporated for $10,000. The company plans to install a bucket system at a cost of $15,000 and will develop 300 acres of coal land with a daily capacity of five cars. Purchase of the mining equipment needed is to be made soon.

Patrick Calhoun, president of the Inland Waterways Co., Louisville, declares that by **next winter large quantities of coal will be moving into Louisville by water** from the Kentucky River section of eastern Kentucky and from the Kanawha river section of West Virginia, the company having arranged to go ahead with installation of barge unloading equipment at the old Consolidated Coal Co. yard in Portland, Louisville, where an incline and other equipment will be installed for mechanically transferring coal from barges to yards and to railroad cars for distribution about the city and to other points on a combination water and rail haul. The company is now operating several towboats and barges and is having additional equipment built for its use.

The Kentucky Utilities Co., Louisville, an Insull organization, operating great transmission lines in both the eastern and western Kentucky fields and utilities in various sections of the state, at its annual meeting in Louisville on Feb. 27, **re-elected directors and officers.** Samuel Insull is chairman of the board, Harry Reid, president; L. B. Herrington vice-president; and A. A. Tuttle, secretary. The report showed an increase of surplus from $272,108 to $400,429 for the year. During that period the company completed 121 miles of additional transmission lines in the coal fields, and now has 504 miles of sucn line in service. Plans call for additional generating capacity for eastern Kentucky to take care of increasing demand from the coal operations. It is believed this demand will become much greater as the Louisville & Nashville R.R. carries out its plans for spending large sums in improving service to the coal fields of southeastern Kentucky.

MINNESOTA

The bill proposed before the Minnesota legislature to sell coal on the basis of heat units, by a system of grading, **has been dropped.** The bill was based upon a proposition from Fuel Commisioner Bowen.

Judge McGee, of Federal Fuel Administrator fame in Minnesota, **has been named for a federal judge in this state** and the nomination has been confirmed in the Senate. As Fuel Administrator the Judge antagonized many, but he had many friends who have been pushing him for this position.

MISSOURI

A coal mine has been opened on the Luys' farb, east of Carthage, and is being operated by H. C. Campbell, D. W. Short and M. Branson, of Purcell. Several tons of coal already have been taken out and operations will be pushed. The shaft was sunk about a year ago but little mining has been done since that time. The mine seems to be in the heart of a coal bed.

George McGuire and James Holman, who have been in charge of a coal mine at Vibbar, Mo., have **leased 40 acres near Chillicothe**, and have brought equipment to open a new shaft. The mine is to be tunneled into the side of a hill. McGuire and Holman report they have 25 experienced miners they will bring here as soon as the shaft is ready.

C. C. Carpenter, of Trenton, who has just returned from Woreland, reports that **27 coal mines have been opened in the vicinity of Woreland** recently. The mines are strip mines and the coal is shipped direct to Kansas City. According to Carpenter the payroll of the mines in one month amounted to $100,000 and, because of the shortage of houses, there were 100 tents in the town before the cold weather set in.

NEW YORK

Assemblyman Coughlin, of Kings County, has offered a resolution to the State Assembly at Albany **calling on the federal government to operate the mines and distribute coal.** Mr. Coughlin maintains that the fuel shortage this winter was due in large measure to the absence of unified action and co-operation between the mines and the railroads.

The city **water works of Buffalo** has asked for bids on **furnishing 45,000 tons of "three-quarter slack" coal**, tenders to be opened March 20.

A pure coal bill was introduced in the State Senate at Albany March 5 by Senator Ryan, of Rensselaer. Under its provisions it would be a misdemeanor for any person, firm or corporation to sell or offer for sale as coal any fuel mixed with coke, charcoal, slag, limestone or slate, unless the purchaser was notified in advance of the adulteration.

The Perryman-Burns Coal Co., Inc., has been organized to deal in anthracite and bituminous coals, with offices at 90 West Street, New York City. David P. Burns, and his brother Archibald P. Burns, both formerly connected with the Tuttle-Burger Coal Co., are members of the new concern. Archibald P. Burns, who covered the New Jersey territory for the Tuttle-Burger company, will represent the new concern in that state.

Koppers coke ovens, arranged in two batteries of 57 ovens each, together with byproduct and benzol plants, coal- and coke-handling equipment, etc., **are to be built at the Lackawanna plant (at Buffalo) of the Bethlehem Steel Co.** Construction will be started at once and it is expected that the plant will be completed within a year.

OHIO

The Besola Coal Co., St. Clairsville, has been chartered with a capital of $25,000, to mine and sell coal, by W. E. Lahm, J. O. Somers, B. H. Beatty, Laura L. Somers and Emma C. Beatty.

The Middle West Coal Co., of Cincinnati, has announced the appointment of **Burke H. Keeney**, as manager and treasurer to succeed E. H. Doyle.

The property of the **Caledonian Coal Co.**, of Columbus, consisting of 385 acres and an operating mine on the T. & O. C. R.R., south of New Lexington, **has been sold to D. J. Malone**, of Fort Smith, Ark. The consideration was in the neighborhood of $168,000.

The Romaine Coal Co. has been chartered with an authorized capital of $350,000 to mine and sell coal in Jefferson County. Incorporators are Fred H. Clark, Frank R. McGee, M. B. Cole, A. B. Imhoff and J. S. Butts.

H. W. Hawk, head of the Long Hollow Coal Co., of Nelsonville, has returned from Pittsburgh, where he closed a deal for the purchase from the National Fireproofing Co. of a large acreage adjoining his property. This will be used to enlarge his mine and modern equipment will be installed, including shaker screens. The mine will be electrically equipped.

S. H. Robbins, president of the Youghiogheny & Ohio Coal Co., has been appointed chairman of the board of directors and **acting president of the Midland Bank**, Cleveland, until such time as a successor to William P. Sharer is named. Mr. Robbins also is president of the Northern Coal & Dock Co. and the Progress Coal Co. He also is a director of the Big Vein Coal Co.

The Piney Fork Coal Co., a subsidiary of the Hisylvania Coal Co., of Columbus, which was opened several years ago as a stripping operation, **has been converted to a drift-mining proposition**, as all of the coal that could be mined by stripping has been taken.

At the Canton and Columbus plants of the Timken Roller Bearing Co. provision is being made for a **considerable increase in production** of Timken tapered roller bearings. At the Canton plant a large modern factory building is in process of construction, on which work is being rushed to completion as rapidly as possible.

PENNSYLVANIA

A per capita tax of 50c. is being levied against the members of those unions which have not contributed **toward the memorial to be erected to John Mitchell**, former president of the United Mine Workers of America. The memorial is to be erected in Scranton to commemorate the unionizing of the hard-coal fields by Mr. Mitchell.

A meeting of the tri-district executive board of the Districts 1, 7 and 9 of the United Mine Workers of America **will soon be called to determine the new policy of the union** in the anthracite field in the coming negotiations with the mine owners. Two courses are said to be open to the men, one the calling of a tri-district convention to frame new demands and the other a referendum vote to have the members indorse a renewal of the demands as framed at the Shamokin convention in January, 1922.

A new mine-cave bill was introduced in the State Legislature on March 6 by Representative Walter W. Kohler of Lackawanna County. The bill provides that any persons, association, copartnership or corporation owning land in any districts in which anthracite or bituminous coal mining has been carried on may send into the mine openings competent mining engineers, agents or inspectors for the purpose of ascertaining to what extent and where and how much coal has been mined from beneath the property of the complainant. It is further provided that the owners or operators of the mine, their agents and employees shall be obliged to render such aid to the investigators as will enable them to make the examination with safety to themselves. Refusal of the owners or operators for a period of ten days after the demand to enter the mine has been made is interpreted by the provisions of the bill as a misdemeanor and upon conviction for this they shall be sentenced to pay a fine not to exceed $10,000. **Representative Kohler also introduced a bill** providing that in all cases where a right to recover damages for injuries to persons or property caused by the subsiding or caving in of the ground covering any mine or excavation the statute of limitations shall begin to run against such right of action from the time of the cave-in.

Augustus McDade, mine inspector of the **Seventh anthracite district**, reports 13 fatal accidents and 18 non-fatal accidents in that district during 1922, while **1,595,942 tons of coal were mined.** Of the coal mined 1,455,746 tons was shipped to market. In the **Thirteenth anthracite district 2,511,550 tons of coal was mined during 1922**, according to the report of Mine Inspector Frank Kettle, and that 2,511,550 tons was sent to market. There were 24 fatal accidents in the mines of the district, of which all but one occurred inside the mines. Richard Maize, Mine Inspector for the **Fifth bituminous district reports 4,203,256 tons of coal and 1,225,028 tons of coke** produced in that district during 1922. There were 12 fatal accidents inside the mines and three outside. The H. C. Frick Coke Co., the largest producer in the district, led with a total output of 2,069,863 tons. There were **4,230,024 tons of coal produced in the 20th bituminous district** in 1922, says Mine Inspector Fletcher W. Cunningham in his annual report. This was 57,882 tons more than in the previous year. Mine Inspector Nicholas Evans, of the **24th bituminous district**, reports that **3,700,193 tons of coal was produced** in that district during 1922, of which 3,600,086 tons went to market. The 1922 tonnage was about 65 per cent of the 1921 tonnage. The report of Harry Phythyon, mine inspector of the **27th bituminous district**, shows **production of coal in 1922** to have been **3,004,317 tons.**

The Fowler bill repealing the state anthracite coal tax law of 1921 has been amended to provide that the repeal shall not take effect until Jan. 1, 1925. When the bill was reached on the third-reading calendar March 6, its sponsor, Representative David Fowler, Lackawanna County, **moved that it be postponed for the present.**

In a letter to W. Clyde Harer, a Representative from Lycoming County and chairman of the House Appropriations Committee, on March 5, **Governor Pinchot suggested a giant power system** based on the principles of quantity production through utilization of the water power of the state and the power that can be generated through steam. He suggested the location of the steam stations near the coal mines and the use in them and in gas works of the by-products of coal now wasted. He asked the appropriations chairman for $35,000 with which to have a comprehensive survey made.

Attorney J. Hayden Oliver, Glen Alden Coal Co. (chairman), W. L. Allen, Scranton Coal Co.; Charles Dorrance, Hudson Coal Co.; W. A. May, Pennsylvania Coal Co., and M. J. Martin, who it was announced will represent various companies, have been chosen to represent the coal companies operating in Scranton and vicinity that will meet a committee representing the city and civic organizations to discuss **remedial mine-cave legislation.** The committee consists of fifteen members, ten representing the city and its organizations and five the coal companies.

Governor Pinchot on March 7 informed a delegation of Scranton citizens interested in the repeal of the anthracite coal tax that he was **opposed to the repeal.** He said that the state needed the money and that four-fifths of the tax was paid by residents outside the state.

The Board of Directors of the **Lehigh Valley Coal Sales Co.** have declared **a dividend of $2** per share payable April 2, 1923, to those stockholders of the company who are holders of full share certificates of stock, registered on the company's books at the close of business March 15, 1923.

The Pittsburgh Coal Co. report for 1922, just issued, shows an **output for the year of 6,612,717 net tons**, of which 5,452,255 was

produced and 1,160,462 tons purchased, a decrease from 1921 of 2,343,845 tons, or 26 per cent. For this, of course, the strike was responsible. The net earnings for the year, after full charges for interest, depletion and depreciation, but before deducting Federal income tax, were $3,714,952.84. After payment of dividends and 1921 taxes the surplus on Dec. 31, 1922, was $2,932,-714.22, an increase of $148,822.56 for the year. Full quarterly dividend payments for the year were declared on preferred stock and 3½ per cent was paid on common stock. Employees own 10,444 shares of preferred stock and 11,401 shares of common. Acreage exhausted in 1922 was 666, leaving unmined reserves owned of 164,351 acres and under lease 634 acres.

Dever C. Ashmead, associate editor of *Coal Age*, gave an **illustrated talk on "The Mining and Preparation of Anthracite"** at a meeting of Wilkes-Barre Rotary, Tuesday, March 13. James Purdue, a mining engineer, assisted in the presentation of the subject.

The administration is reported to be planning a tax on bituminous coal. What effect such a measure will have on the move to repeal the anthracite tax measure is a matter of speculation. The need for addition revenue is becoming more and more apparent, if the present educational program is to be carried out.

TENNESEE

Officials of the United Mine Workers of America in District No. 19 have annouced that **more than a hundred mines in southwestern Kentucky and Tennessee have signed wage agreements** with their men by which the 1920 wage, based on the Central Competitive Field agreement, is to be continued in force until April, 1924. The agreement will affect 8,000 miners, the union officials declare. The production of coal in Tennessee during 1922 totaled 4,-350,000 net tons, valued at $15,000,000. O. P. Pilam, state mine inspector, declares that the 1922 production was the lowest in efficiency in the history of the state. There were 13,500 miners employed, compared with 10,653 in 1921, and the production was about equal to 1921, but less than 1920 when 6,921,848 tons were produced.

The Pocahontas & Sewanee Coal & Iron Co., of Pikeville, has the development of 1,900 acres of coal land under way and this will have a 2,000-ton capacity. The company is planning to install electrical equipment and machinery.

UTAH

The I. C. C. has given permission for the **construction of the Utah Central Railroad's line in the coal-producing sections of the state.** The line will be about 50 miles long, with main and side tracks, and will tap the Denver & Rio Grande Western R.R.'s main line near Castlegate and extend southeast through Carbon County into the northeastern section of Emery County, terminating in Huntington Canyon, where the principal mines it is intended to develop are located. The company holds thousands of acres of coal land on patents and also leased government land. Several of the mines have already been developed to a limited extent as wagon mines. It is estimated that many millions of tons of coal lie undeveloped in the section about to be tapped. Former Representative James H. Mays heads the $1,000,000 company which will construct the road. The company will be permitted to retain for a period of 10 years any revenues which it receives from operating the line in excess of 5.75 per cent of the capital invested.

The Columbia Steel Corp. will construct the first unit of its blast furnace immediately, the contract having already been let.

VIRGINIA

E. White Atkinson has opened offices in Norfolk to represent the Coal River Collieries, owned and operated by the Brotherhood of Locomotive Engineers. This is the first time this company has made an effort to handle its coal through an agency here. An unfavorable freight rate has made it impossible for these mines to compete in the Hampton Roads trade, but arrangements have been made with the Chesapeake & Ohio Ry. whereby this rate is placed on a basis for competition with other coal dealers.

The Old Virginia Coal Co., has been incorporated at St. Charles with a capital of $10,000 and with E. B. Cullen as president and E. L. Fuller as secretary.

The City of Norfolk will receive bids this week for 12,000 tons of coal of mixed grades, to be delivered beginning April 1. The bidding, usually, is confined somewhat largely to local wholesalers. No announcement has been made of other bids being asked at any time soon.

WEST VIRGINIA

When a state road is damaged through loss of material support resulting from the removal of coal adjoining the right of way, a coal company is responsible, according to an opinion of Attorney General E. T. England of West Virginia.

The Gulf Smokeless Coal Co. and the **Gulf Coal Co.**, both of Beckley, have changed their principal office from Beckley to Tams. W. P. Tams, of Tams, is the president of both of the companies. The Logan Fuel Co. will hereafter have its principal office at Charleston instead of Huntington.

The Jack Run Coal Co., which was recently incorporated with a capital of $60,-000, has perfected its organization with the election of John Batturo as president and William D. Andrea as secretary. The company has 24 acres of coal land under development and expects to add to this holding to make the daily output 250 tons.

The Fire Creek Pocahontas Fuel Co. of Huntington, which was recently incorporated with a capital stock of $150,000, has organized by electing the following officers: President, C. B. Lee; Secretary, William J. Harvie; Manager; Harold E. Wilson. The company succeeds the Hump Mountain Smokeless Coal Co. It contemplates making extensive repairs and installing new machinery, so as to develop 200 acres of coal land to produce a daily output of 350 tons.

Among the recent West Virginia companies to place orders for Nolan automatic feeders are the Grey Eagle Coal Co. for their Grey Eagle No. 1 mine, the Flat-Top Pocahontas Coal Co. at Herndon, and the American Coal Co. at McComas.

Holdings of Sewickley coal in the Scott's Run field of Monongalia County have been materially increased by **E. H. Gilbert** and **R. M. Davis**, operators in that field, through the purchase of 138 acres of coal land in Cass district.

The Andrew Coal Co., operating at Granville, on the Monongahela Ry., in Monongahela County, has been sold to Fred Tropf and Frank L. Bowman of Morgantown for the sum of approximately $150,000 and in the future its mine will be operated by the **Tropf-Bowman Coal Co.**, with general offices in Monongalia County.

The Blackfield mines, hitherto owned and operated by F. B. and J. M. Black and associates as a portion of the Atlantic Coal Co. operations, **have passed into new hands**, the Blacks having disposed of their entire interests in the property, which had been in litigation for some time. Frank Romesberg, of Salisbury, is president of the new company; C. M. Bird, vice-president and superintendent; John Kretchman, secretary, and Norman Romesberg of Garrett, treasurer. Included in the deal are 1,000 acres of coal, together with tipple and bin which has a capacity of 600 tons, 200 mine cars, two steam dinkey engines, two electric motors and all other equipment that was used in operating the Blackfield mines.

The Edna Gas & Coal Co. of Fairmont, which was recently incorporated with a capital of $1,500,000, has been organized with the election of R. M. Hite as president. The company has purchased from the Jamison Coal & Coke Co. their Lehigh and No. 11 mines, with a daily capacity of 1,000 tons. The company plans to install additional equipment, which will increase the output of the plants to 2,000 tons a day.

The Main Island Creek Coal Co. at Omar has been incorporated with a capital of $25,000 by J. Henry Bell and W. H. Courtney of Lexington, and W. H. Hoover of Nicholasville, Ky.

The Weyanoke Coal & Coke Co. of Springton, of which R. D. Patterson is president, has consolidated with the **A. J. Patterson Pocahontas Co.** and the capital increased to $1,000,000.

The Richland Coal Co., of Wheeling, has increased its capital from $200,000 to $600,000.

H. H. Randolph and associates, of Burch, plan to organize the **Milestone Coal Co.** and to invest $1,000,000 in coal properties.

Cleveland people, including F. M. Kirk and others, having acquired the capital stock of the Melrose Coal Co. of Fairmont, have also **leased the mine of the Consolidation Coal Co.** at Enterprise. The company will operate under the name of the Melrose Coal Co. Pittsburgh coal is produced at the Enterprise mine, which has a capacity of from eight to ten cars of coal a day. The Melrose company is capitalized at $100,000.

Directors and officers were elected at the annual meeting of the **Atlantic Smokeless Coal Co.** held in Welch, on Feb. 27. The board as elected will be composed of the following: George Wolfe, Beckley; W. M. Black, of Lynchburg, Va.; Dr. C. R. Woolwine, of Davy; Dr. J. Howard Anderson, of Marytown; Richard Hancock of Lynchburg, Va.; J. B. Clifton, of Beckley; A. F. Wysong, of Princeton. Following the election of the board of directors, that body selected the following officers: George Wolfe, Beckley, president, treasurer and general manager; Dr. J. Howard Anderson, of Marytown, vice-president; W. M. Black, Lynchburg, secretary, and R. E. Brockman, superintendent. This company operates a mine at Asco, McDowell County, in the Tug River field. Before adjournment of the board of directors **a dividend of $26 a share was declared**, payable as of March 1.

In a $150,000 fire at Beckley late in February the Ernest M. Merrill Engineering Co. of Beckley, lost much valuable equipment, data, records, paraphernalia, etc. Within a period of 24 hours however the company had rehabilitated itself in temporary quarters and was ready to transact business as usual.

The Westmoreland Coal Co., of Philadelphia **paid $120 an acre for 5,500 acres of coal land** on Ford Fork of Little Coal River owned by the Laurel Coal & Land Co., of which Major J. E. Chilton and former Senator William E. Chilton were the largest stockholders. Through this purchase the Westmoreland company becomes one of the largest holders of coal land in southern West Virginia.

Under the terms of the **Byrer Bill** (Senate Bill No. 360), which its sponsor states is **patterned after the anthracite tax bill in Pennsylvania**, there would be levied upon every net ton of coal mined, washed, screened or otherwise prepared for market in West Virginia a tax of 2 per cent of the gross value thereof when prepared for market. Such a tax would be assessed at the time the coal was mined. Taxes so received would be placed to the credit of the "state producers' depletion fund," 50 per cent of which would be paid to the State Road Commission to be applied to the payment of interest and sinking fund, and 50 per cent of which would be paid to the boards of education in each county in the state.

Authority has just been granted by the directors of the **West Virginia Coal & Coke Co. to improve the Norton plant** of the company in Randolph County which will involve an expenditure of between $50,000 and $60,000, including the construction of a new store building, an office building, a central warehouse or supply house, a machine shop and complete equipment and a general repair shop to repair mine cars and motors. The company also will construct a macadam road leading to the Norton plant as well as a concrete bridge across Grassy Run. The office of the company physician, superintendent, chief electrician and others connected with the plant in an executive and clerical capacity will be in the new office building. Work will be begun as soon as plans and specifications can be drawn. The Norton plant is the largest of the West Virginia Coal & Coke Co., having a capacity of about 2,500 tons of coal a day.

The invasion of Logan County by representatives of **the American Civil Liberties Union**, which had been widely advertised for several weeks, **failed to make much of an impression** in the vicinity of the mining center. The party of speakers addressed perhaps 1,000 people from the court house steps in the city of Logan, on Sunday night, March 4. Instead of encountering opposition, as members of the party had indicated they expected, they were given an opportunity to present their arguments and to test the "right of free speech." The addresses were mild. Those of Heber Blankenhorn, of the Bureau of Industrial Research, and of the Rev. Henry S. Huntington, associate editor of the *Christian Work*, made little or no impression and met with no response. That of Arthur Garfield Hays, being of a humorous nature and dealing with his experiences in Pennsylvania, excited the risibilities of the crowd.

Not only have extensive improvements been made at the No. 1 mine of the **Pond Creek Coal Co.**, of which J. C. Sullivan is president, but it is now proposed **to build two miles of railroad** in order to permit the further development of the property. A contract has been let for the railroad construction to the No. 2 mine, where a modern plant will be built, fully equipped and capable of producing from 2,000 to 3,000 tons of coal a day. At the No. 1 mine the finishing touches have just been put on an all-steel tipple and it is proposed to build additional mining houses, all with a view to increasing the output of the No. 1 mine, which adjoins the property recently acquired by the Ford Motor Co.

WISCONSIN

Frank R. Bacon was elected **president of the Cutler-Hammer Co.** of Milwaukee, at a recent meeting of stockholders. The only change in the nine officers who also constitute the board of directors was the election of F. L. Pierce as vice-president in place of A. W. Berresford, who retired. The other officers of the company are as follows: Second Vice President, B. L. Worden; Treasurer, F. L. Pierce; Assistant Treasurer, L. F. Vogt; Secretary, T. E. Barnum; Manager of Operations, H. J. Wiegand; General Sales Manager, W. C. Stevens; Assistant to the president, J. C. Wilson; Director of Purchases, W. S. Hopkins.

WYOMING

According to Denver newspapers, the **Chicago, Burlington & Quincy R.R. is planning the construction of a $2,500,000 branch railroad in northeastern Wyoming and southeastern Montana** to tap the semi-bituminous coal fields of that region. Right-of-way from Sheridan, northeast into the Rosebud District, is being purchased by agents of the railroad. Construction is to start this spring.

"The new road will be a sixty-mile branch and will start from the main line which runs from Billings, Mont., through the southwest corner of South Dakota, through Nebraska, and into the network of Burlington lines which lead into Chicago, Kansas City, St. Louis and Omaha."

It is also reported that the Northern Pacific railway is about to build a similar line south from its main line, taking off at Forsyth and extending into the same fields. The Northern Pacific, already operating mines at Red Lodge, is expected to develop large stripping operations in the district.

CANADA

A resolution empowering the Standing Committee on Mines and Minerals to inquire into coal supplies, costs, transportation, desirable inter-provincial action and other **means whereby Canada may be rendered self-sustaining as regards bituminous coal**, is to be moved in the House of Commons at Ottawa, this session, by a Nova Scotia member who asks that the committee inquire into the necessity and possibility of supplying substitutes for coal.

That the government feels that **no good purpose would be served by appointing a special committee of the House to consider Canada's fuel problem** with a view to the adoption of a national and British coal policy for Canada, was the information given in the House at Ottawa a few days ago in answer to a question placed on the order paper by T. L. Church, North Toronto.

Because of the fact that no election of officers was held for District 26, United Mine Workers of America, which, according to the district constitution, must be held on the second Tuesday of December of each year, Springfield Local has forwarded a resolution to the International Executive Committee in which it is **requested that President Lewis take immediate action to enforce the constitution.**

At a well-attended meeting of the Associated Boards of Trade of eastern British Columbia, at Trail, on Feb. 22, it was resolved that **"price adjustments in the coal industry are long overdue**, and that, in the interest of the industry itself, dependent industries and the general public such adjustments should be made forthwith, and that the Dominion Government should probe the whole situation."

The British Empire Steel Corporation, which aims at an output of 400,000 tons of coal this year, made a good beginning in January, considering that much idleness was caused by severe storms. The output for the month shows an increase of 175,000 tons over that of January, 1922. In order to carry out its plans its **transportation equipment will be renewed on a large scale.**

Traffic News

Freight cars of all descriptions **on order by railroads** on Feb. 15 **totaled 97,932**, according to a report by the Car Service Division of the American Railway Association. This was an increase of 29,600 over the number on order on Jan. 1 last and 6,578 more than were on order on Feb. 1 last. Of the total orders placed, 49,646 are for box cars, an increase of 14,029 since Jan. 1. **Coal cars on order totaled 37,680**, an increase since the first of the year of 13,462. Reports up to Feb. 15 also showed that orders had been placed for 1,915 locomotives, which was an increase of 470 over the number on order on Jan. 1 last. Of the total number ordered, 1,407 were freight locomotives, 376 passenger and 132 switch engines.

New equipment ordered by the Pennsylvania Railroad system to be placed in service this year—some of it already being delivered—involves an expenditure of more than $57,000,000. In order to handle its share of the country's growing business—normally about 11 per cent of the freight and 17 per cent of the passenger traffic of the nation—the company is making large additions to its present car and locomotive capacity. Since the first of this year the Pennsylvania has ordered 500 new steam locomotives. Last fall work was started on changing 50-ton trucks to 70-ton trucks under about 10,000 coal cars, which will increase the capacity of these cars by approximately 31 per cent.

The New York Central R.R. has been ordered by the Ohio Public Service Commission to join its lines at Hopedale with the Pittsburgh & West Virginia Ry. Coal operators complained that the lack of such a connection was causing them great loss and preventing the proper distribution of coal in Ohio. The case is scheduled to be argued before the Interstate Commerce Commission on March 27.

In pursuance of a recommendation by the Federal Fuel Distributor the Interstate Commerce Commission issued March 5 **Service Order No. 39**, directing the New York, New Haven & Hartford R.R. **to permit the docking of the vessel Maumee out of its turn** at Belle Dock, New Haven, Conn., so as to provide coal to meet an emergency at the plant of the Springfield Gas Light Co. at Springfield, Mass. This order was necessary because of the regulations that vessels must be docked in turn. There were 23 ships ahead of the Maumee, which was carrying coal for the gas light company. On the showing that the coal supply of the company will have been exhausted prior to the docking of the Maumee in turn, the Interstate Commerce Commission issued its service order and also authorized priority in the placement of cars for the transportation of the coal from New Haven to Springfield.

Adjustment of Lake freight rates is being sought by operators from northern West Virginia who attended a conference early in March in Washington at which complaint was made that all-rail rates from southern Illinois were discriminatory. Representatives of the railroads said that there would be no change in the rates. The coal operators however propose to appeal directly to the presidents of the various Lake coal-carrying railroads and hope to obtain a reduction of 57c. a ton as compared with present rates, such a reduction to be absorbed by the railroads and the boat owners. It is contended by northern West Virginia shippers that inequitably low all-rail rates will interfere with the movement of a larger tonnage over the Great Lakes.

Coal dealers conferred recently with officials of the Virginian and Norfolk & Western railways regarding the **proposal** of the latter **to discontinue barging coal to waterfront customers**. No decision was reached. The proposal was scheduled to be effective April 1, but no tariffs have been published and the regulation cannot go into effect at that time.

Shipments of railroad locomotives from the principal manufacturing plants **declined slightly in February**, according to figures published by the Department of Commerce from compilations by the Bureau of the Census. Unfilled orders, however, reached a new high record at 2,220 locomotives at the end of February, an increase of 432 during the month. Both shipments and unfilled orders on foreign account continue to decline and now form but a small proportion of the total.

Association Activities

Clarksburg Coal Club

At the last meeting of the Clarksburg Coal Club of Clarksburg, W. Va., the opinion prevailed that lack of direct rail connection to New England was penalizing mines on the Baltimore & Ohio and led to an expression of hope that it might be possible to induce the Pennsylvania R.R. to extend its line from Fairmont to Clarksburg. Among those who spoke at the meeting were A. Lisle White, formerly president of the Northern West Virginia Coal Operators' Association, and "Uncle Dan" Howard, one of the well known operators of northern West Virginia. It was stated during the discussion that operators on the Pennsylvania near Fairmont were able to obtain as much as $1 a ton more for their product than operators on the Baltimore & Ohio, just across the Monongahela River from the Pennsylvania. It also was stated that the operators on the Pennsylvania system could ship direct to New England, whereas the B. & O. is unwilling to accept shipments to New England states owing to the difficulty in having cars returned. Clarksburg operators desire the Pennsylvania extended to Clarksburg not only because it will enable them to broaden their markets, but will afford them better transportation facilities than they assert they are now receiving.

Obituary

Milton Graves, 58 years old, operator of a small coal mine near Carbon, Ind., committed suicide recently by shooting himself through the head with a large revolver. He leaves a widow. No cause was given for the act.

Henry E. Patrick, 71, vice-president of C. M. Moderwell & Co. at Chicago, died Feb. 28, in a hospital near his home in Oak Park, a Chicago suburb. Death followed a stroke of paralysis. Mr. Patrick left the dry goods business in Chicago 20 years ago to join the Moderwell organization and was one of the first sales managers to handle Franklin County (Illinois) coal, now a leader among Western fuels. Mr. Patrick remained sales manager until 1917, when he was made vice-president and a director of the company. Burial was in Marengo, Ill.

Charles T. Boynton, 65, vice-president of Pickands, Brown & Co., a coal, coke and iron concern of Chicago, died of pneumonia Feb. 28 at his home in Highland Park, near Chicago. He was also vice-president and a director of the By-Products Coke Corporation, of Chicago.

M. L. Marks, a well-known coal salesman in Chicago for Walter Bledsoe & Co., an Indiana operating concern, died Feb. 28. He was once with the Dering Coal Co. and later with the Lill, Robinson Coal Co., which was absorbed by the Consumers Co.

Coming Meetings

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24. Secretary-treasurer, J. G. Crawford, Chicago, Ill.

The American Mining Congress will hold its twenty-sixth annual convention in conjunction with the **National Exposition of Mines and Mining Equipment**, Sept. 24-29, at the Milwaukee Auditorium, Milwaukee, Wis. Secretary, J. F. Callbreath, Washington, D. C.

Indiana Retail Coal Merchants' Association will hold its annual meeting April 25 and 26 at the Severin Hotel, Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

International Chamber of Commerce will hold its second general meeting in Rome, Italy, March 19-26.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., Dec. 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

The Gas and Fuel Section of the American Chemical Society is arranging a second sectional meeting at the New Haven meeting of the American Chemical Society during the first week in April. The section program will consist of papers on gas and fuel chemistry and a symposium on motor fuels, held jointly with the petroleum division.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, THURSDAY, MARCH 22, 1923 Number 12

By Order of the Commission

THERE was a time in this country when private initiative, enterprise and resourcefulness were sufficient to meet an emergency. If a man's wagon became bogged, friendly neighbors gathered and pulled it out. If a family was in distress, townspeople flocked to the rescue. It was not considered either necessary or good form to lay the matter before the magistrate first and obtain an order from him before administering to the needs of those in distress. No good citizen thus evaded responsibility.

A few weeks ago a gas company in a New England town was short of coal. A vessel bringing a fresh supply arrived at the port and was ready to discharge its cargo and relieve the emergency. But there were twenty-three other ships in the harbor which had arrived prior to this vessel's coming. There was a rule, just a man-made rule, to provide fair play and expedite business, a rule of the railroad controlling the pier at which these boats must dock to discharge their cargoes, which prescribed that each vessel must take its turn.

Before that ship could have reached the dock and been unloaded, the gas company would have been out of coal. Such a thing was obviously against the public interest, but do you suppose those in charge did the perfectly obvious neighborly thing and hurried that boat into the dock, unmindful of turn, and hastened the coal to the anxious gas company?

Not at all. Those good old days must be gone. A railroad company operated the dock and stood between the boat and the consumer. Railroads no longer have initiative, or if they have any they do not seem disposed or privileged to use it. At any rate the matter was taken from far-off Connecticut to Washington and soon there issued from the office of the Interstate Commerce Commission at the capitol city Service Order No. 39, which orders and directs the railroad to do the obvious thing. This is government regulation with a vengeance.

Branding All for the Sins of a Few

THE popularity of the "coal barons" has had recent certification in the attacks of Hearst's *New York American*. That paper has been carrying a series of stories and editorials assailing the hard-coal operators for shipping "fireproof coal." There is a definite background of fact behind these stories, for refuse and uncleaned coal—material almost unburnable—has been loaded out of the region this winter. Anything would sell if it were called hard coal, and advantage has been taken of that situation by certain unscrupulous people. The facts, however, have been grossly distorted. Nothing else was to have been expected from the *American*, which delights in and is devoted to sensationalism.

No matter, it seems, from what angle it is desired to attack the coal men, some facts can be found to support the desire. It will be remembered that during the war another New York paper, employing the pen of Sophie Irene Loeb, assailed the coal barons for *not* shipping this self-same culm to New York.

Back of the attack of the *American* is the fact that a few are guilty of shipping unmerchantable coal—the Federal Fuel Distributor names six, it is alleged. The names are little known in the trade—certainly not regular producers or shippers. But what they have done in giving the whole hard-coal industry a bad name will star their names in history. No one should get the idea that culm-bank and washery coal is necessarily dirty coal, for it is not. Out of total daily shipments of around 6,000 cars of all coal from the anthracite region, not to exceed thirty cars per day is this "unmerchantable coal"—which is less than 1 per cent of the household sizes. For this the whole industry is damned.

There is one satisfactory answer to such a situation and that, of course, is suitably to punish those who are guilty. The Interstate Commerce Commission has decided that it will keep hands off and has notified the Fuel Distributor that it cannot accede to his request to withhold cars from the offenders, who it appears have been known in Washington for some time. The sufferers and complainants are householders in far-off cities, yet they are supposed to bring civil or criminal action to obtain redress. Instead they find solace in the vituperation of the *New York American*. The General Policies Committee of the Anthracite Operators tells their side of the story in a page advertisement in the *American*, which story the paper seeks to tear down in a half-page editorial in the same issue.

It may occur to some that the real cause of the trouble, the real reason why it has been possible for some to market "fireproof coal," is the long strike of last summer, when some 40,000,000 tons of production was permanently lost.

Technical Education

NO one is a worse salesman than the average college professor. Poorly indeed have the deans of colleges sold the scholastic idea. Apologists they are one and all of them. In general the maker of the poorest product is immeasurably the best salesman. The eye of the professor is on the mind of the man himself, not on the public reaction to his services. He is more interested in the work of creation than in the art of distribution.

Every now and then college professors have traveled the country round with the cry "What is wrong with our work? You are a practical man, versed in big affairs. Tell us what is wrong with us?" Thus approached the superiority complex masters the magnate thus addressed and he accordingly swells up and delivers himself as follows: "Your college men are not versed in the management of men; they do not under-

stand accounts and organization. They view matters from a scientific, not a practical, point of view." And the college dean accepts that as a good answer.

But why? The qualities of management and discrimination are largely innate. Their students have it or they have it not. If they have it not, if they ever get it it will be by experience, not by education. In that matter they are like other men. The remarkable fact about college training is that men who have it succeed more generally than men not having it. Hardly a man around the mines who has a college education fails to make some sort of mark in the world. His average certainly is higher than that attained by other men. You will see him dominated at times—not always or unduly often—by men of exceptional genius who lack college education, but even then he nevertheless is essential to the organization to which he belongs. He fills a gap that the man of exceptional talent but no scholastic training could not fill.

Treat it as we will we cannot make tool steel out of material without the proper constituents or with earthy minerals that are of a harmful character, but who, knowing this, will condemn the treatment of steel?

It is remarkable how often we find men of education succeeding solely because of their knowledge. They are not born leaders of men; they are not of the right social quality. All they have is the gift of the schools and yet they are recognized, for what they know makes them sought by others.

Today the human element is getting less important. Brute strength is giving way to science. Our mines are filled with machinery that is handled best by men knowing thermal units, volts, amperes, tensile strengths and chemical qualities better than they do brute strength and the characteristics of the superman. Furthermore, it has been found that on the whole the college man has been a safer industrialist than that numerous class of practical men who have dominated for a time solely by a disregard of human rights and aspirations.

Again and again we hear that readers do not think and thinkers do not read—a most pernicious doctrine. Carried to its true conclusion it would prove beyond peradventure that the peasants of Russia who have not even the rudiments of education are superior to the people of the United States, who as a whole are the most persistent readers of any time or country.

Fayol's Dome Theory

IN ANDREW B. CRICHTON'S paper on "Mine-Drainage Stream Pollution," before the American Institute of Mining and Metallurgical Engineers, he says that "in one area, where about half the coal had been removed and where the average depth was about 500 ft. and the rainfall 3,300 gallons per acre per day, it was found that 27 per cent of this water percolated into the mine and was pumped out." Clearly the measures above the mine were broken to the surface. We must therefore presume, if we believe in Fayol's dome theory, that the measures failed to choke themselves in a height of 500 ft. or, rejecting the theory, we must assume that the rocks were cracked by subsidence and came down into the mine with their relative position unchanged. Further, we must assume that as the surface rocks in subsidence are compressed what cracks are formed over the subsided area near the surface, if indeed there be any, must be closed and consequently most of the water must first enter through the cracks in surface rocks over the unmined coal rather than in those over the subsided area.

In Howard N. Eavenson's paper on "Mining an Upper Bituminous Seam After a Lower One Has Been Extracted," delivered before the same body, he holds that it is possible to mine a seam in some cases 19 ft. above one that has been extracted. What, then, becomes of Fayol's dome theory? It would certainly appear that there must be crevicing above the dome in the case of the mine mentioned as being situated about 500 ft. below the surface and that the dome cannot be 19 ft. high in the instance cited by Mr. Eavenson.

What is left of the Fayol theory may safely be granted to its advocates. There *is* a tumbling of rock for a certain distance above the coal, but with this the subsidence and cracking has to do only as a causative action. Both would occur and but little modified in character or extent if the tumbling did not take place. The adjustment depends mainly on subsidence, and the bending that takes place as the result of that subsidence is the cause of most of the tumbling of the rock which Fayol noted and which every engineer or laboring man who ever stepped inside a mine could not fail to observe.

It should be added that some of the tumbled rock falls only because it is really a drawslate and does not act monolithically with the main roof above. That freedom of action is the determinant quality of a drawslate. It is not monolithic with the roof. It "draws" away from it; therefore it is a *draw*slate. We frequently do not realize, however, that the depth of the rock thus drawn away may be greater than we expect.

But what, indeed, does it profit us to argue? Evidence enough has been obtained in England and perhaps in other countries that fracture and, less often, caving occurs over the pillar. All over the European coal fields we learn definite facts about subsidence. So Fayol's theory has been disproved times without number. Why should we still be bound by the fairy tales in the mining books of our youth? Surely we know that in our wooded, leaf-strewn and bramble-covered areas and from the surface of our plowed fields and glacial drift we are not likely to see evidences of cracks in the rocks below. It is only when houses and streams are met that the secret is revealed, and not often then, for our houses are not on the rock as a rule and the tilting is gradual, and when it takes place and notice is taken of it, no one has laid out the pillar line on the surface to serve as evidence that Fayol's theory has failed again to explain what happens when land is undermined.

Such cracks, moreover, are often so small as to escape observation even when they may appear on the top of the ground. It is interesting to note that General O'Toole declared that streams were robbed of their water by mining even before extraction had reached that part of the coal bed that lay immediately under them, thus evidencing that even with room-and-pillar workings the tearing action extends beyond the line of operation.

We must learn to look under the surface of things. We have been prone to judge of a rope by the fractures which can be seen in an exterior inspection and now we learn that in the heart of the rope occur breakages and cracks not visible to the inspector but equally expressive of rope failure. To deny all that we do not see is fatuous in the extreme.

In Half Century Depth of Coal at Wilkes-Barre More Than Doubles and Thickness Falls 30 per Cent

Mines Leaving Pillars to Support "Buried Valley" Forced to Work Deep Beds—In 45 Years Coal Output per Employee Has Fallen 38 per Cent, Fine Sizes Being Considered Whether Sold or Stored

By Dever C. Ashmead*
Kingston, Pa.

EXHAUSTION of the thick coal that made the early mining of anthracite famous compelled producers last year to open thinner beds or suffer material decreases in output. In *Coal Age* of Feb. 22 it was recounted how in the Lackawanna district there had been a decrease in average thickness from 6.83 ft. in 1872 to 4.88 ft. in 1922 and an increase in average depth from 229 ft. to 268 ft. This paper covers the area adjoining on the south—the Wilkes-Barre district. In the period between 1872 and 1922 the average thickness there declined from 8.76 ft. to 5.90 ft. and the average depth of working increased from 170 ft. to 399 ft.

The Wilkes-Barre district includes that part of the Northern anthracite coal field southwest of the Lackawanna-Luzerne County line. The beds of coal lie at greater depths in this district than they do in the Lackawanna district. (See Fig. 13.) At the southern edge of the anthracite field the beds pitch steeply and with many rolls and some faults. In the northern end the beds are flatter and only along the outcrop are they steeply pitching. The coal beds in this district are thicker than in the Lackawanna district and there are more of them. From the top down the beds are: Abbott, Kidney, Hillman, Stanton, Five Foot, Cooper and Bennett (Baltimore), Skidmore, Top Red Ash, Middle Red Ash, and Bottom Red Ash.

One of the noteworthy features of this district is the "buried valley." An old river bed filled with glacial drift as much as 200 ft. thick in places, this buried valley is heavily laden with water and quicksand. It is extremely dangerous to mine under this cover unless there is heavy rock intervening. Very little second mining has been done in this area, although some of the mines are being forced to do it in order to maintain their output.

The beds mined in the Wilkes-Barre district in 1872 averaged 8.8 ft. in thickness (Fig. 15). In the fifty years that have intervened there has been a steady decrease in the average thickness of coal mined and by 1922 the weighted average thickness had declined to less than 6 ft. Exhaustion of the thicker measures and increased workings in thin coal accounts for this change. (See Fig. 16.) In 1872 about 82.5 per cent of the beds being mined were thicker than 5 ft. and 65 per cent of the beds were thicker than the average for the year 1922. In 1922 57 per cent of the beds were thicker than 5 ft., against 82.5 per cent in 1872. Prior to 1882 no coal less than 3 ft. thick was mined, but by 1922 practically 10 per cent of the beds mined were less than 3 ft. in thickness and some were reported at less than 2 ft.

TABLE XI—AVERAGE DEPTH AND THICKNESS OF COAL MINED IN THE WILKES-BARRE DISTRICT, IN FEET

Years	Average Depth of Workings	Average Thickness of Beds	Years	Average Depth of Workings	Average Thickness of Beds
1872	170	8.76	1902	377	6.62
1877	250	8.59	1907	374	6.30
1882	296	8.75	1912	382	6.06
1887	330	7.64	1917	380	6.03
1892	350	7.66	1922	399	5.90
1897	341	6.80			

The Red Ash bed is one of the most important in this district. In most parts of the field it is divided into two and in some places into three splits. It is the lowest workable bed in the district and it also is one of the thickest. Most of the first mining has been completed in the Red Ash bed and in places second mining is now going on. The next bed of major importance is the Baltimore, which is divided quite generally into two main splits known as the Cooper and the Bennett. In the lower regions of the anthracite field the Baltimore bed is known as the Mammoth. First mining has been

Footnote—This is the second of a series of articles by Mr. Ashmead describing mining conditions in seven sections of the anthracite region. The first of the series, covering the Lackawanna district, appeared in *Coal Age* of Feb. 22, 1923. The third of the series, describing the district will appear in an early issue.—Editor.

*Assistant editor, *Coal Age*.

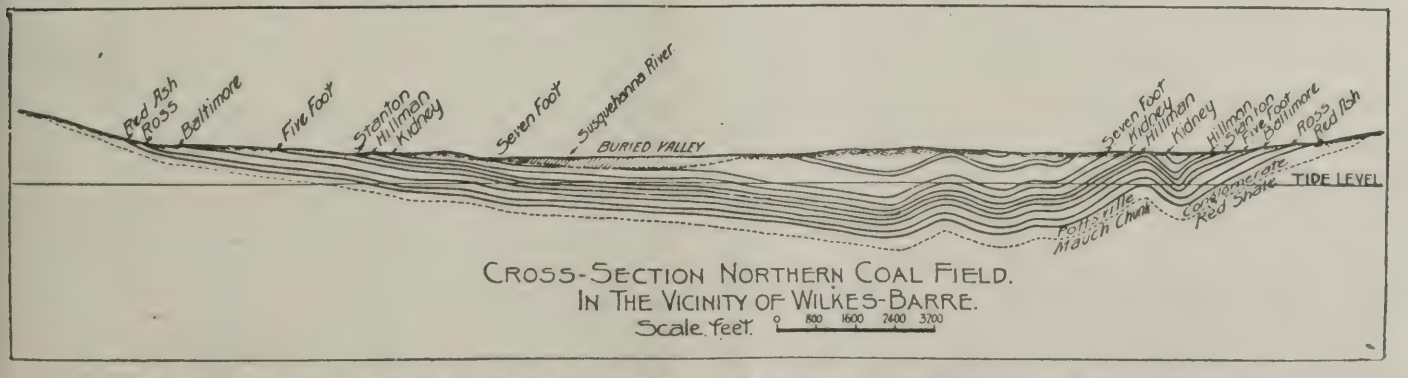

FIG. 13—SECTION OF THE NORTHERN ANTHRACITE FIELD IN THE VICINITY OF WILKES-BARRE
This is a typical section and shows the general flatness of the beds. It also shows that the beds are steeply pitching near the outcrop, particularly on the southern side of the field. The beds here are of greater depth than in the Lackawanna district

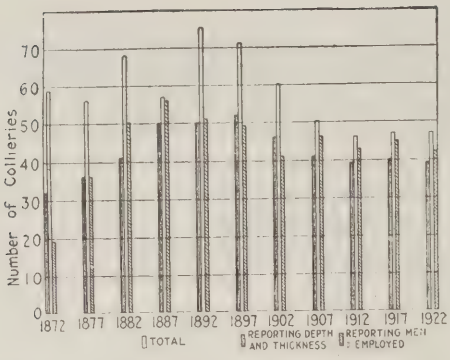

FIG. 14—NUMBER OF COLLIERIES IN THE WILKES-BARRE DISTRICT

The diagram shows the number of plants from which statistics on depth and thickness of coal mined were available and the number from which data was obtained with respect to men employed, as compared with the total.

practically completed and second mining is progressing generally throughout the district. Most of the first mining that remains is in thinner beds, as thin as 2 ft. The thinner beds, as the Ross, Skidmore, Stanton, Abbott and Five Foot, are scattered throughout the vertical section of the measures, so although the lowest bed is being mined to exhaustion, the mining of the thinner beds, which lie below the Cooper and the Bennett, pushes the average depth of workings down. Since there will be increased outputs from the thinner beds it appears that the average depth of workings will remain about what it is now.

Fig. 17 shows the change in the depth of workings in the Wilkes-Barre district. From 1872 to 1892 the depth increased rapidly, then, as the Red Ash and the Baltimore beds were developed to a maximum the average depth increased slowly, gaining only about 35 ft. in the period from 1892 to 1912, an average rate of 1.7 ft. per year. From 1912 to 1922 the change in the depth had decreased to a rate of 0.8 ft. per year. Some time in the not distant future, when the lowest measures become completely second mined, it may be expected that the curve will turn over and the average depth decrease.

In studying Fig. 18, which shows the percentage of beds being worked at 100 ft. intervals, it will be noted that since 1892 there has been no increase in the maximum depth, 1,400 ft., at which the beds are being worked. The percentage of beds within 100 ft. of the surface has been constant as has the percentage of beds between the 300 and 400 ft.

The increase in the average depth of all beds being worked is due to less workings between the 100- and 300-ft. intervals. From 1892 to 1922 the percentage of beds in the 200- to 300-ft. level decreased from 28 to 19, while in the same period the percentage of beds in the 100- to 200-ft. interval decreased from 27 to 20. At the same time the percentage of beds being worked deeper than 400 ft. has increased about 15 per cent.

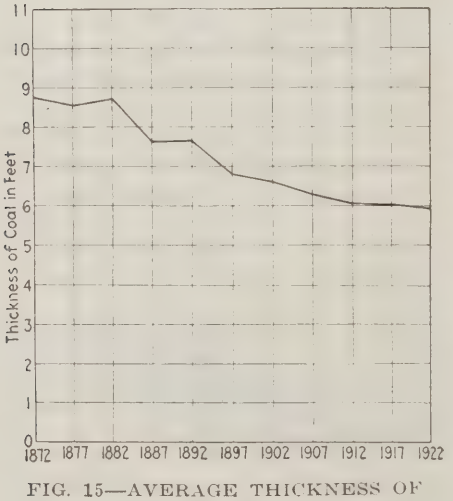

FIG. 15—AVERAGE THICKNESS OF COAL MINED AT FIVE YEAR INTERVALS IN THE WILKES-BARRE DISTRICT

The method of making the calculations shown in this diagram was the same as that described under Fig. 3 in the first installment of this article (*Coal Age*, Vol. 23, No. 8, p. 324).

TABLE XII—NUMBER OF COLLIERIES IN THE WILKES-BARRE DISTRICT

Year	Total as Reported by the Department of Mines	Having Depth Data	Having Thickness Data	Having Tonnage Data
1872	59	32	32	19
1877	56	37	37	37
1882	68	41	41	50
1887	57	50	50	56
1892	74	50	50	51
1897	71	52	52	49
1902	60	46	46	41
1907	50	41	41	46
1912	46	39	39	42
1917	47	40	40	45
1922	47	39	39	42

A rather interesting story is told by the sets of curves in Fig. 19, showing the average thickness of the beds at each 100-ft. interval in depth. In practically every case the thickness of the beds being mined has decreased

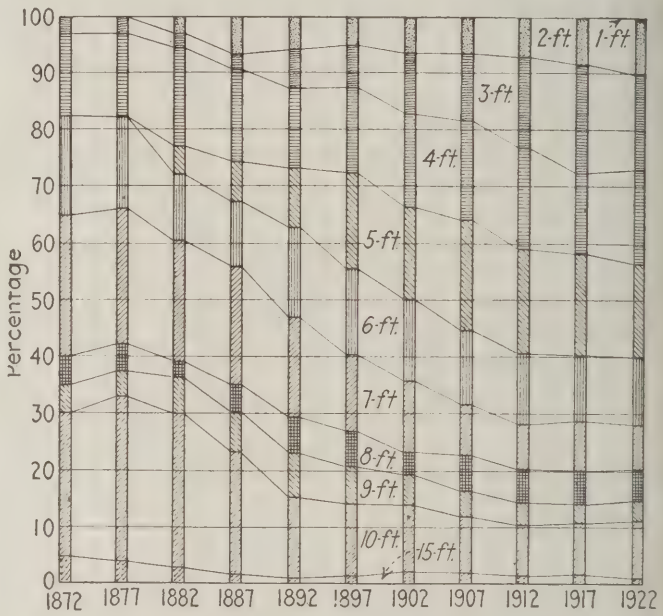

FIG. 16—PERCENTAGE DISTRIBUTION OF NUMBER OF BEDS WORKED BY THICKNESS IN THE LACKAWANNA DISTRICT

This diagram shows the percentage of the total number of beds of each thickness mined in each year.

from 1872 to date, but the greatest decrease in thickness has been in those intervals which lie between 600 and 1,000 ft. Here, in the earlier years, the beds averaged around 15 ft. in thickness, but now, due to the increased number of thin beds being worked, the average has dropped to about 7 ft. Below 1,000 ft. mining in late years of the thin splits of the Red Ash bed has reduced the average. The same is true at depths between 600 and 1,000 ft., where also there has been increased mining of the Ross and Skidmore beds.

The increase in power required to produce coal is illustrated in Fig. 20, which shows a declining output

TABLE XIII—POWER USED IN THE PRODUCTION OF ANTHRACEIT IN THE WILKES-BARRE DISTRICT

Year	Boiler Hp. Installed	Engine Hp. Installed	Tons of Coal Produced per Boiler, Hp.	Tons of Coal Produced per Engine, Hp.	Tons per Mule Daily	Number of Underground Locomotives per 100,000 Tons of Annual Production
1877	11,970	.....	1.64	....	20.32	....
1882	19,800	19,166	1.17	1.21	16.30	....
1887	24,870	.....	1.23	....	15.93	....
1892	31,500	.....	1.21	....	16.18	....
1897	27,900	.....	1.90	....	19.99	....
1902	54,526	69,167	1.08	.85	19.90	.09
1907	67,031	77,335	.70	.61	16.87	.28
1912	83,947	100,125	.64	.53	15.53	.70
1917	96,914	129,125	.61	.47	19.56	1.98

TABLE XIV—MULES AND LOCOMOTIVES IN MINES IN THE WILKES-BARRE DISTRICT

Year	Mules in Service	Inside Locomotives	Year	Mules in Service	Inside Locomotives
1877	963	...	1902	2,960	16
1882	1,442	...	1907	2,780	40
1887	1,916	...	1912	3,404	122
1892	2,337	...	1917	3,724	363
1897	2,662	...			

TABLE XV—PRODUCTION AND DAYS WORKED AT ANTHRACITE MINES IN THE WILKES-BARRE DISTRICT

Year	Production in Gross Tons	Average Days Worked	Year	Production in Gross Tons	Average Days Worked
1872	1,112,829	...	1902	5,287,853	106
1877	2,895,836	156	1907	12,002,337	216
1882	4,744,117	224	1912	13,121,885	220
1887	6,961,850	212	1917	14,789,815	283
1892	7,166,809	192	1921	13,875,753	267
1897	7,240,881	135			

per boiler and engine horsepower installed. As the difficulties of mining increase with the working of thinner beds at greater depths, ventilation and haulage requirements become greater, better preparation is needed and a larger amount of water must be handled, hence more power is required than in the old days when the beds were thick and not so deep, when hauls were short and coal was cleaner.

In 1877 the average output was 1.65 tons per boiler horsepower installed. In 1917 it had declined to 0.63 ton, a drop of more than 62 per cent. In other words, it is now necessary to install 1.59 hp. to produce a ton

TABLE XVI—MEN EMPLOYED IN THE PRODUCTION OF ANTHRACITE IN THE WILKES-BARRE DISTRICT

	Total	Inside Employees	Outside Employees	Miners and Miners' Laborers	Inside Company Men
1872	2,681	1,894	787	1,413	481
1877	9,199	6,291	2,908	4,127	2,164
1882	12,110	8,160	3,950	5,260	2,900
1887	17,489	11,409	6,080	7,694	3,715
1892	19,990	12,960	7,030	8,695	4,265
1897	24,741	16,110	8,367	10,910	5,200
1902	21,973	15,437	6,536	9,999	5,438
1907	28,144	20,637	7,597	13,353	7,284
1912	29,983	22,680	7,303	14,483	8,197
1917	28,803	21,712	7,091	13,932	7,780
1921	29,466	22,483	6,733	13,796	8,687

compared with 0.6 hp. in 1877. Corrected for small sizes not included in the earlier years, the figure for 1877 would have been about 0.4 hp. instead of 0.6.

During the last fifteen years the decrease in the amount of coal produced per horsepower installed has not been as great as previously, due to better practice in power generation and because to some extent in this district power is purchased.

Data with respect to haulage in the Wilkes-Barre district, as shown in Fig. 21, are not very enlightening. There is no apparent explanation, save that of possible errors in the annual inspectors' reports, for the discrepancies indicated for 1897 and 1902. If records for these two years be thrown out, it appears that the amount of coal hauled per mule has remained constant even since the introduction of the underground locomotive. This is taken to mean that the length of haul has rapidly increased in this district and has not as yet reached its maximum, as was concluded with respect to the Lackawanna district.

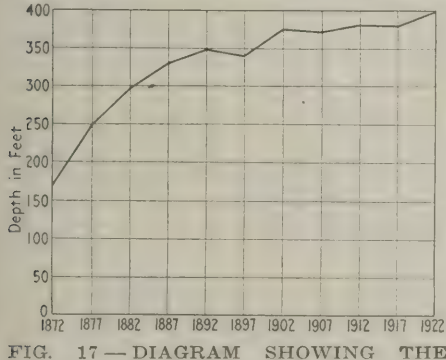

FIG. 17—DIAGRAM SHOWING THE INCREASING DEPTH AT WHICH ANTHRACITE HAS BEEN MINED IN THE WILKES-BARRE DISTRICT FROM 1872 TO 1922

The method of making the calculations on which this diagram is based was described in *Coal Age*, Vol. 23, No. 8, p. 325.

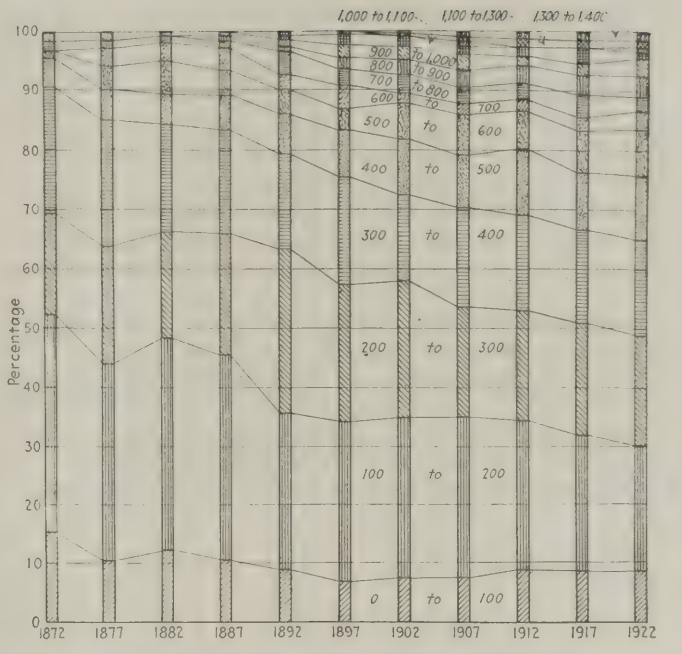

FIG. 18—PERCENTAGE DISTRIBUTION OF NUMBER OF BEDS BEING WORKED IN EACH 100-FT. INTERVAL OF DEPTH IN THE WILKES-BARRE DISTRICT

A count was made of the number of beds being worked in each 100-ft. interval of depth and their ratio to the total determined. The full description of how the calculations were made will be found in *Coal Age*, Vol. 23, No. 8, p. 325.

The average daily output, all men considered, decreased from 1877 to 1882 and then steadily gained until 1902, after which it has dropped to the present time. The explanation of these changes is found in the variations in the average daily outputs of the outside men between 1877 and 1907 and subsequently in the drop in average production by inside men.

The average daily output of the inside men increased in the earlier years to a maximum in 1902 (ignoring 1897 as incorrect), thereafter declining. Corrected for the small sizes, the data show a steady drop in the average from 1877 to 1921. With the final correction to the 8-hour day the figures show a fairly uniform figure to 1902 and thereafter a marked drop. From 1877 to 1921 the drop is from 3.98 tons to 2.45 tons, a difference of 1.55 tons, or 39 per cent. The explanation, as will later be shown, is found in the changes in the records for underground employees.

TABLE XVII—AVERAGE DAILY PRODUCTION OF ANTHRACITE PER EMPLOYEE, WILKES-BARRE DISTRICT, IN GROSS TONS

	Tons of Coal Produced per Day								
	Per Total Employee			Per Inside Employee			Per Outside Employee		
	Reported	Corrected for Small Sizes	Corrected to 8-Hour Day	Reported	Corrected for Small Sizes	Corrected to 8-Hour Day	Reported	Corrected for Small Sizes	Corrected to 8-Hour Day
1877	1.63	2.39	2.12	2.95	4.32	3.98	6.37	9.34	7.49
1882	1.18	1.67	1.47	2.95	3.67	3.38	5.35	7.60	6.08
1887	1.28	1.63	1.43	2.88	3.68	3.40	5.41	6.91	5.53
1892	1.51	1.85	1.62	2.89	3.55	3.28	5.32	6.54	5.23
1897	1.77	2.07	1.82	3.33	3.88	3.59	6.42	7.50	6.00
1902	1.85	2.00	1.86	3.22	3.40	3.33	7.60	8.20	6.78
1907	1.64	1.75	1.65	2.69	2.87	2.75	7.40	7.86	7.00
1912	1.65	1.71	1.61	2.63	2.73	2.62	8.16	8.48	7.57
1917	1.50	1.50	1.50	2.41	2.41	2.41	7.38	7.38	7.38
1922	1.48	1.48	1.48	2.31	2.31	2.31	7.71	7.71	7.71

TABLE XVIII—AVERAGE DAILY PRODUCTION OF INSIDE MEN

	Miners and Miners' Laborers		Inside Company Men		
	Reported	Corrected for Small Sizes	Reported	Corrected for Small Sizes	Corrected to 8-Hour Day
1877	4.49	6.58	8.56	12.56	10.05
1882	4.02	5.70	7.29	10.35	8.28
1887	4.27	5.45	8.85	11.30	9.04
1892	4.30	5.30	8.77	10.77	8.56
1897	4.92	5.76	10.33	12.07	9.66
1902	4.97	5.38	9.14	9.87	8.15
1907	4.16	4.41	7.63	8.11	7.22
1912	4.12	4.28	7.27	7.56	6.73
1917	3.75	3.75	6.72	6.72	6.72
1921	3.76	3.76	5.98	5.98	5.98

In the earlier years there was a steady decrease in the average daily output per outside employee. Corrected to include steam coal and to the 8-hr. day the figure for 18877 was about 7.5 tons as against 5.25 tons in 1892, a decrease of 2.25 tons, or 30 per cent. During this period there were few improvements in mining methods and because of the increasing proportion of refuse in the coal and the old style equipment for preparation, each year more and more slate pickers were required for the same total production.

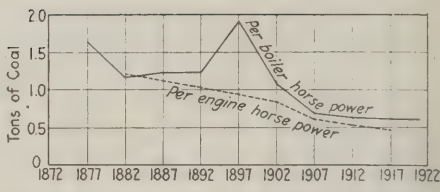

FIG. 20—DAILY PRODUCTION OF COAL PER BOILER HORSEPOWER AND ENGINE HORSEPOWER INSTALLED, 1877-1921

About 1892 mechanical improvements in the preparation of coal were introduced and by 1897 their effect began to show in an increased daily output by outside men. From that time on the gain was steady as the mechanical cleaning devices replaced manual labor in the breaker. From 1892 to 1921 the output per day per outside man increased 2.50 tons, or 47.8 per cent. At the present time the rate of increase is beginning to flatten out, but it is reasonable to expect that it will continue to mount with advances in the art of preparation.

Production of coal by the miner and miner's laborer has materially declined. The record for the Wilkes-Barre district declined from 6.58 tons in 1877 to 3.75 tons in 1921, or 2.83 tons. If 1897 be ignored, the decrease in the past 45 years is steady except for the four years 1917-1921.

The average daily output per miner and miner's laborer as finally corrected was 6.58 tons in 1877, decreasing to 3.76 tons in 1921, or by 42.9 per cent. This drop compares very closely with the decrease in output of the Lackawanna district of 43.7 per cent in the same period of time.

A study of the final corrected curve for miner and miner's laborer in Fig. 23 is interesting. In the period 1877 to 1882 there was a decided drop, possibly explained by an incomplete classification of the men in the mine inspectors' reports. Ignoring the record for 1897 there is little change in the figure up to 1902, a decrease of but 0.32 ton in the twenty years. Referring back to Fig. 16 it is seen that in 1877 but 3 per cent of the total number of beds worked were 3 ft. or under, that in 1902 this had

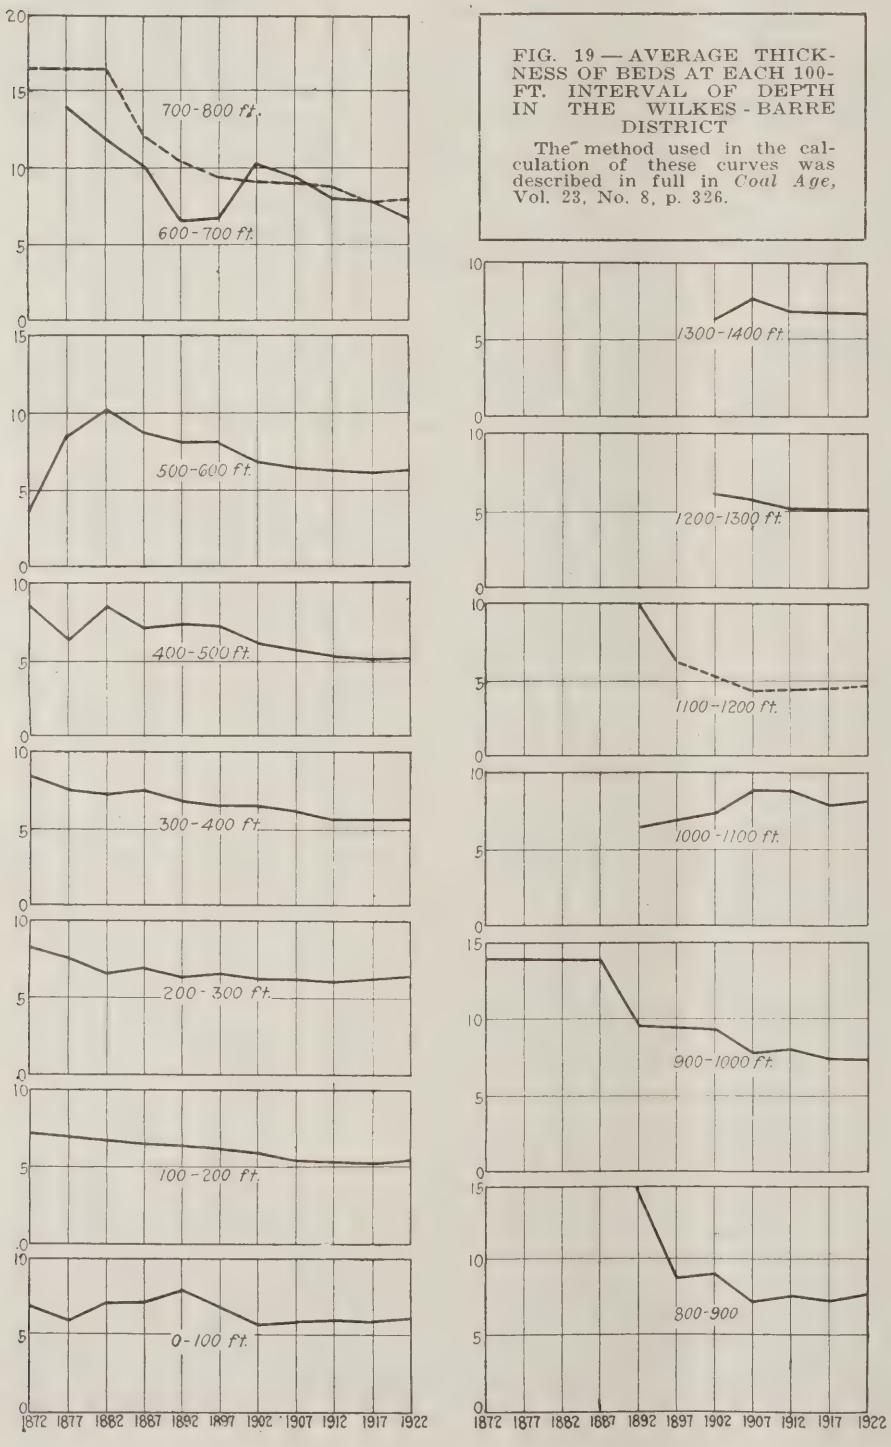

FIG. 19 — AVERAGE THICKNESS OF BEDS AT EACH 100-FT. INTERVAL OF DEPTH IN THE WILKES-BARRE DISTRICT

The method used in the calculation of these curves was described in full in *Coal Age*, Vol. 23, No. 8, p. 326.

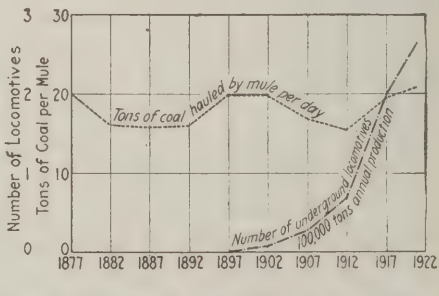

FIG. 21—TONS PER MULE AND PER LOCOMOTIVE

This diagram shows the average daily tonnage hauled per mule and number of underground locomotives per 100,000 tons of annual production in the Wilkes-Barre district.

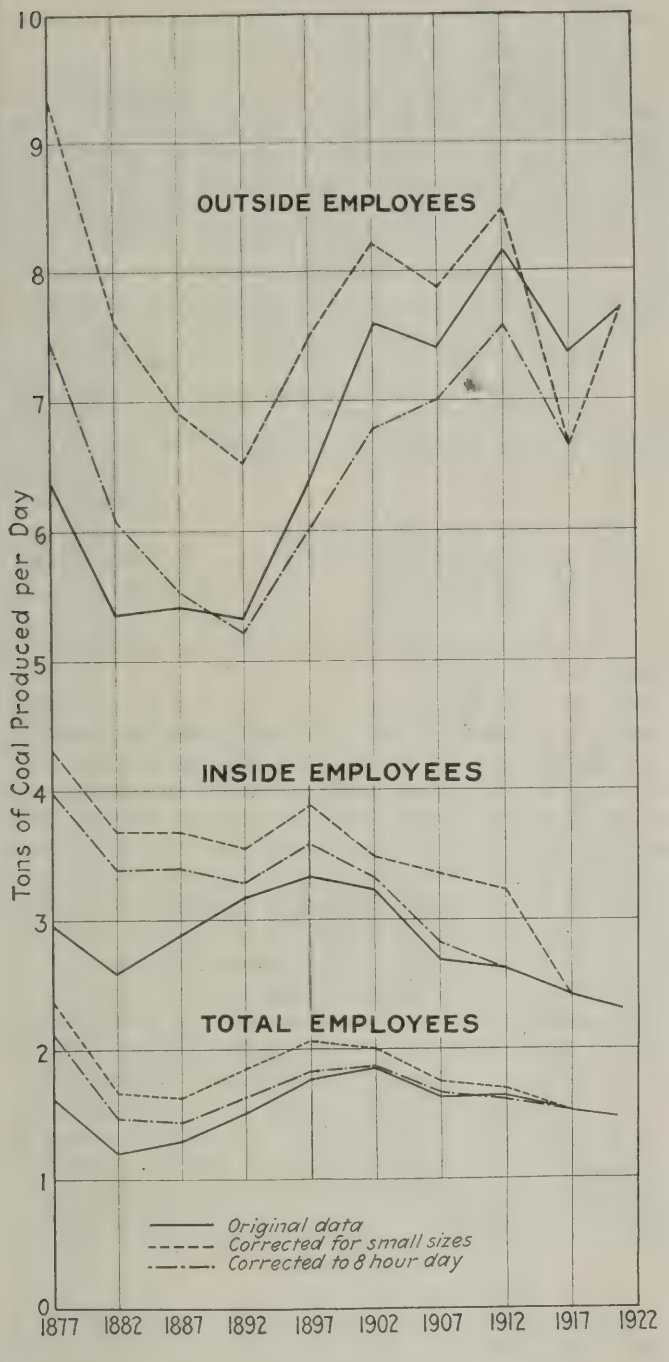

FIG. 22 — AVERAGE DAILY PRODUCTION OF COAL PER EMPLOYEE IN THE WILKES-BARRE DISTRICT, 1872-1921

The figures are shown as calculated from the reports of the state mine inspectors, also with corrections for small sizes of coal not reported as production in the earlier days, and finally to a uniform 8-hour day. The solid lines represent the figures as calculated from the original data taken from the reports of the mine inspectors in the anthracite region of the Department of Mines of the State of Pennsylvania. The days worked were determined by multiplying the number of employees by the number of breaker days at each colliery. Then the total number of employees in the district was divided into the sum of the men-days at each colliery and the result considered the weighted average number of days worked. The next step was to divide the total number of employees into the total production of the collieries to determine the average annual output per employee. This, divided by the weighted number of days worked, gave the average daily output per employee.

The dash line shows the correction for small sizes. It was impossible to obtain exact tonnages of small sizes of fresh mined coal shipped in these earlier years but from information in the reports of the Girard Estate and in the *Coal Trade Annual* estimates were made. For later years the actual figures are given by the U. S. Geological Survey. These estimates are: 1872, sizes under chestnut shipped, 8.8 per cent; 1877, 16 per cent; 1882, 26.8 per cent; 1887, 30 per cent; 1892, 42 per cent; 1897, 57 per cent; 1902, 82.7 per cent; 1907, 84.6 per cent; 1912; 90.3 per cent. Knowing the true percentages of small sizes produced, the corrections were made by difference from these estimates. As no washery coal is considered in these figures the percentage of small sizes from washeries was not taken into consideration.

increased to 6 per cent. Beds averaging between 3 and 4 ft. in thickness represented 3 per cent of the total in 1882 and in 1902 about 11 per cent. Beds 4 ft. or less in thickness thus represented 6 per cent of the total in 1882 and 17.5 per cent in 1902. It must be remembered, however, that there is a time interval between opening up a bed and bringing it to production, so that although the number of thin beds increased in proportion to the total number, the proportion of production from these beds did not increase equally fast. Although no evidence is available to substantiate it the belief is held that there was little production from the thin beds. In the early years the operators doubted the practicability of mining these thin beds of coal. This accounts for the slight decrease in average daily production per miner and miner's laborer from 1882 to 1902. From 1902 to 1921 there was a marked decrease in the average daily output of miners and miners' laborers — some 1.62 tons per man, a rate about five times that of the preceding period. This cannot be accounted for by greater number of thin beds being worked but by more intensive mining of those that were opened up. In the discussion of Fig. 11 in the preceding article on the Lackawanna district (*Coal Age*, Vol. 23, No. 8, p. 328) the reasons for the decreased output of inside company men were explained and the same general reasoning applies to the discussion of Fig. 23. The curves in the upper part of this diagram apply to the inside company men. It will be noted that the change in output per man (as corrected) is downward from

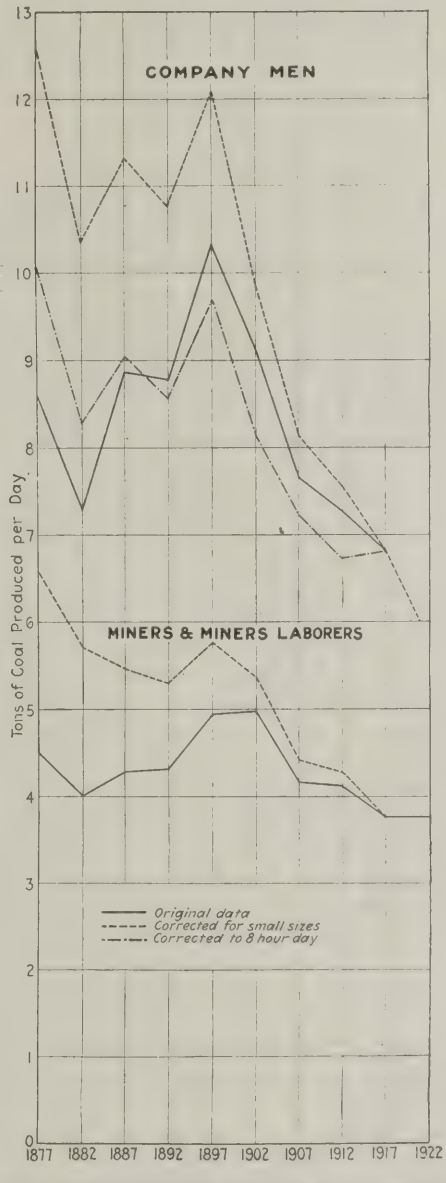

FIG. 23—AVERAGE DAILY PRODUCTION FOR INSIDE EMPLOYEES IN THE WILKES-BARRE DISTRICT

The figures are shown as calculated from the reports of the state mine inspectors, also with corrections for small sizes of coal not reported as production in the earlier days and finally to a uniform 8-hour day. In the calculation of these curves the same method was used as in calculating the curves for a number of tons of coal produced per day per total man employed. No correction was applied for hours worked for the miners, as they worked the same time under all conditions. It is again necessary to call attention to the fact that the points for the year 1897 are too high and should be neglected and that the average for the years 1892 and 1902 is considered to more nearly represent the facts.

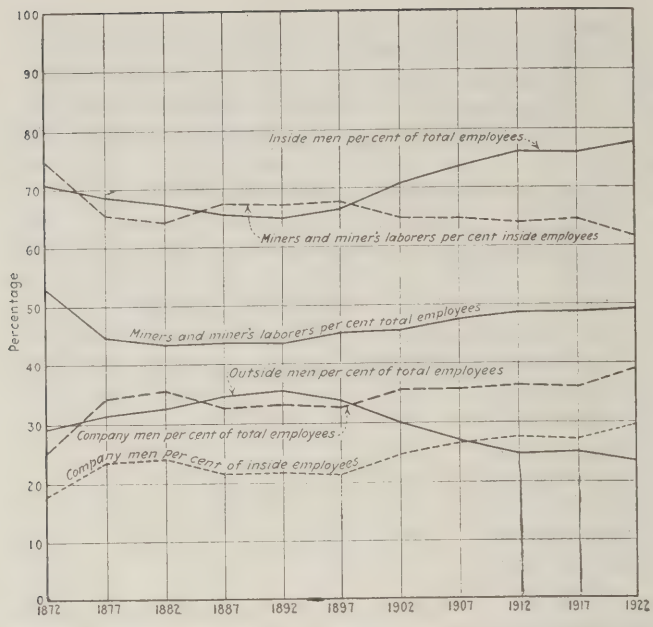

FIG. 24—PERCENTAGES OF EMPLOYEES BY CLASSES IN THE WILKES-BARRE DISTRICT
From the annual reports of the mine inspectors of the Department of Mines of Pennsylvania.

1877 to date with the exception of the period 1882 to 1887. The development of the collieries in this district has been very rapid. In 1877 the output was 2,895,836 tons and in 1921 it had reached 13,875,753 tons. Large areas were opened up, the average underground haul increased and a larger supervisory force was required. For instance, although the average number of tons per mule has remained fairly constant (if the two high points of 1897 and 1902 are ignored) the number of mules has increased greatly.

During the development period more company men are employed in these thin beds than afterward. As production increases the number of inside company men is decreased in proportion to the number of miners. Thus in certain periods the average daily output for inside company men is lowered, and later, as production from these beds is increased and more miners are employed in working them, their average daily figure is lowered.

As evidence of economies effected in the surface operation of the mines it will be noted that from 1892 to 1921 the percentage of outside men decreased from 35.2 of the total to 22.8 and the inside force has correspondingly increased. The percentage of miners and miners' laborers has decreased compared with the total number of inside employees because of the larger number of inside company men who today must be employed underground in order to cope with difficulties which greater depth and thinner beds unfortunately impose.

TABLE XIX—PERCENTAGE OF GIVEN CLASSES OF EMPLOYEES TO TOTAL EMPLOYED

	Inside Employees	Outside Employees	Miners and Miners' Laborers	Inside Company Men	Miners and Miners' Laborers *a*	Inside Company Men *a*
1872	70.9	29.1	52.9	18.0	74.6	25.4
1877	68.4	31.6	44.9	23.5	65.6	34.4
1882	67.4	32.6	43.5	23.9	64.4	35.6
1887	65.2	34.8	43.9	21.3	67.4	32.6
1892	64.8	35.2	43.2	21.4	67.0	33.0
1897	66.2	33.8	45.2	21.0	67.7	32.3
1902	70.3	29.7	45.5	24.8	64.7	35.2
1907	73.4	26.6	47.2	26.2	64.7	35.3
1912	75.7	24.3	48.4	27.3	63.9	36.1

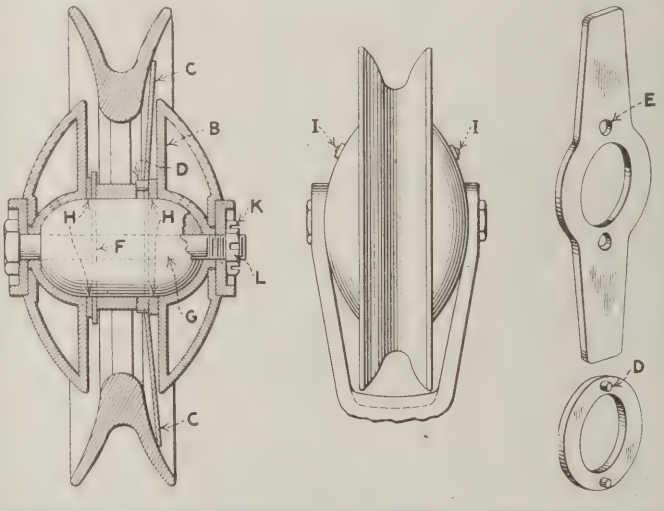
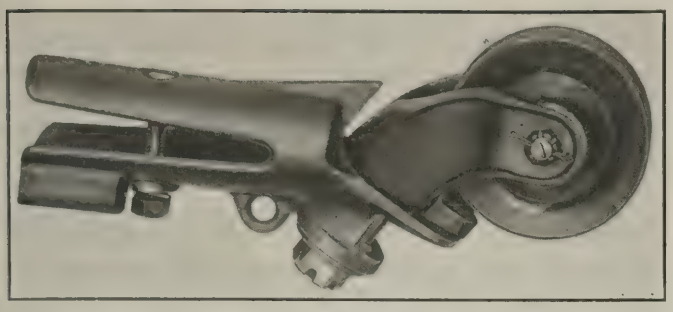
1922	77.2	22.8	48.8	29.4	61.2	38.6



a Percentage to inside employees.

Trolley Wheel Which Passes Electricity Through Side Bearings



A WELL-BALANCED trolley wheel which when operating runs without vibration is that made by the Thornton Trolley Wheel Co., of Ashland, Ky. The hub of this wheel is unusually large and runs on a bearing, *F*, of which the cross-section taken laterally is almost elliptical and taken in the plane of rotation of the wheel is circular. Within the width of the wheel this bearing is like any other bearing, only larger. Only the ends of the bearing are curved.

The elliptical ends fit into two side bearings, *B*, which are held in place by a horizontal tie bolt, *G*, passing from end to end of the bearing. These side bearings do not revolve. Owing to their shape they readily can be adjusted to take up wear. They also take up all side thrust. They give adequate bearing surface and keep the wheel from wobbling from side to side as it runs along the wire. A contact spring is provided which carries the electricity to the harp without passing through the oil by which the bearing is lubricated, thus insuring that no loss of current or heating will thereby be occasioned.

This contact spring rests against the hub of the wheel and is connected by two small feathers, *D*, with a circular washer, *H*, which fits snugly against the side bearings, *B*. On the opposing side of the wheel the arrangement is the same, but the contact spring is replaced by a short piece of metal, *F*, that makes contact only with the hub of the wheel and not with its rim. Grease or oil reservoirs in the side bearings, *B*, provide for adequate lubrication. Each side bearing is fitted with three small, evenly spaced holes, *I*, for that purpose. These are filled by a grease gun. They will carry enough lubricant to serve for from one to four weeks. It is said that on electric traction work a trolley wheel of this type has run satisfactorily for 50,000 or more miles. With the removal of one cotter pin, *K*; one nut, *L*; and one bolt, *G*; the parts may all be disassembled. It is said that by eliminating vibration arcing is greatly reduced, and the groove of the trolley wheel accordingly is not burned. The absence of vibration also prevents the enlargement of the hole

SECTION AND ELEVATION OF WHEEL; ALSO CONTACT SPRING AND WASHER
Ample bearings in both directions distinguish this trolley wheel from others, preventing the wobbling which is almost a characteristic of wheels of this type. The passage of electricity from the wheel to the trolley head is not a hit-or-miss matter but is definitely provided for by the introduction of the contact spring.

MINE TROLLEY HEAD IN HORIZONTAL POSITION

The wheel, it will be noticed, has a contact spring against the side of the trolley wheel. This carries the current to the side bearing.

in which the harp swivels. The bearing will outlast twelve or fifteen wheels and as a result can be used for a long time.

A Few Days' Traffic May Destroy Brattice Cloth; Elsewhere It May Last a Year*

By George S. Rice,† J. W. Paul‡ and E. H. Denny§
Pittsburgh, Pa.

DATA assembled by the U. S. Bureau of Mines coupled with requests from coal companies have emphasized the desirability of establishing standardized specifications for brattice cloth with particular respect to durability and fireproofing. It is planned to establish these specifications through a co-operative program in which the U. S. Bureau of Standards will make a series of tests of various brattice cloths with respect to fire-resisting qualities and the U. S. Bureau of Mines will continue to assemble field data on the use of that material. Information contained in this report is based on data obtained from coal operators in bituminous districts of Pennsylvania, Alabama, Utah, Indiana, Illinois, Colorado and Nova Scotia.

Jute is used as brattice-cloth material in most of the mines from which reports have been received. The unit weight of this jute varies, ranging from 10 to 27 oz. per square yard, 14- or 16-oz. jute being that most commonly used. The 27-oz. jute was known as "calcutta" jute and apparently was an extra heavy product.

*Report of Investigations, U. S. Bureau of Mines, entitled "Preliminary Investigation of Brattice Cloth Used in Coal Mining," (slightly briefed). †Chief mining engineer, U. S. Bureau of Mines. ‡Chief coal-mining engineer, U. S. Bureau of Mines. §Mine safety engineer, U. S. Bureau of Mines.

Other brattice-cloth material reported includes "manhattan" (apparently a heavy, closely woven, treated jute cloth) and "duck," the former ranging in weight from 20 to 28-oz. and the latter weighing 10-oz. per square yard. The weave ranged from 14 to 16 threads per inch, except in the "manhattan" cloth, the heavier grades of which are 16 double and 32 single and the lighter grades 12 and 15 single.

The life of brattice-cloth varies widely, depending on the conditions under which it is used and also probably to a lesser extent on the kind of cloth out of which it is made and the general conditions of the part of the mine in which it is used. When used on haulageways it wears rapidly due to passage of motors and trips of cars, mules and men. This is particularly true if the roof or the sides of the haulageway are wet or the mine air is saturated with moisture, as the brattice cloth then becomes wet and heavy with water and drags on passing cars.

Moisture a Determining Factor of Life

Cloth used thus, under particularly unfavorable conditions, may last only three days to a week; with especially favorable conditions it may last one or more months. Probably a life of two weeks or less is a reasonable average for brattice cloth in haulageways. Its life may be much longer, however, when used in rooms and as "line" brattice for carrying air to the faces of entries or rooms to prevent possible accumulation of gas, or as a more or less permanent means of deflecting air into pillar workings. When thus used it may be still subject to more or less traffic wear and adjustment and change by bratticemen. When undisturbed by traffic, instances have been reported of brattice cloth lasting for two years, but when used in rooms and for line brattice the life usually is two to twelve months, three or four months being a rough average.

With respect to the effect of the material used or to its weight on the life of brattice cloth, only general statements can be made because conditions of service vary greatly. The heavier material can be expected normally to last the longer, although moisture-absorbing powers and consequent greater tendency to drag on passing motors and trips may in certain places make this conclusion erroneous. One company after test has adopted a 10-oz. duck costing considerably more per square yard than the ordinary jute brattice cloth. The

* F.o.b. Wabash, Indiana

tests indicate a life of two to three months for this duck when used in entries where loaded cars pass under it.

In the majority of instances moisture and sulphur water seem to have a deteriorating effect on brattice cloth. However, two companies report that cloth used in moist places lasts longer than in dry, one company stating that in dry mines the cloth becomes dry and rotten, and moving it from place to place causes it to become rotten and leaky. It seems probable that when in continuous state of wetness or of dryness brattice cloth deteriorates less than when alternately wet and dry.

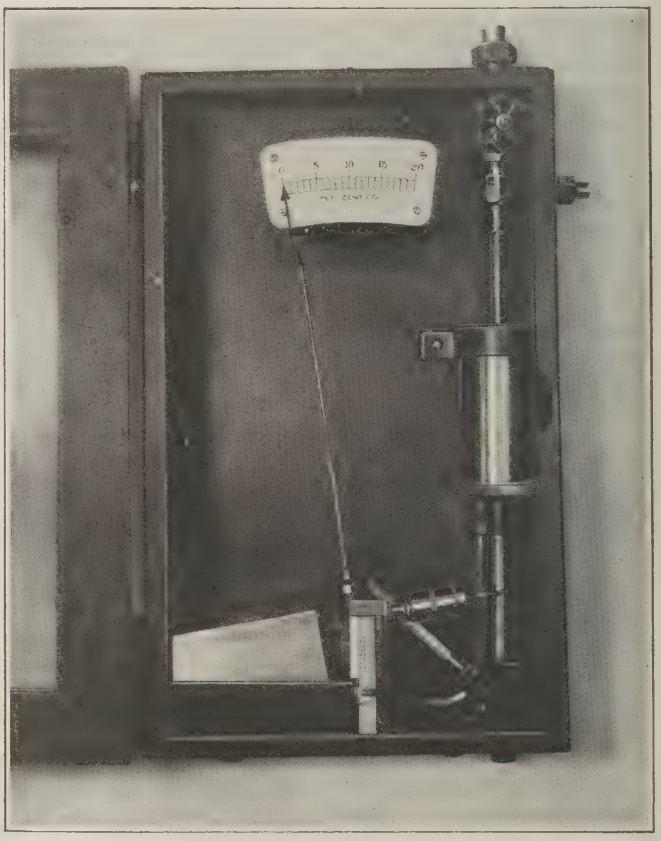
In almost all cases reported the brattice cloth used had been subjected to fireproofing treatment by the manufacturer. Various mining companies reported that they had tested such fireproofed cloth by a carbide-lamp flame and by flame from an ordinary electrician's blowtorch and found the cloth suitably resistant to fire. Tests by the Bureau of Mines indicate that supposedly fireproofed brattice cloth is not always fire-resisting, but is sometimes decidedly inflammable. The fire-resisting qualities of the cloth also change in the mine as the cloth ages and wears. As the chemicals used for treatment usually are more or less soluble, they gradually leach out in a damp place, and most mine atmospheres have a high humidity. Brattice cloth not properly fireproofed may form a distinct fire hazard if exposed to carbide lights, blasting or in contact with electric power wires. No cloth is reported as having been treated for the purpose of increasing its life, one company stating that its experience has shown that preservatives increase the susceptibility of the brattice cloth to fire—this presumably means after some use in the mine—and that no preparation can be devised which will prevent brattice cloth from being torn or frayed under hard usage.

Largest Quantities Used in Gaseous Mines

The cost to mining companies during the period of inquiry (1921-1922) is reported as varying, according to weight or grade, from 14c. to 26c. per square yard for the jute cloth, 14c. being a common figure in the Pennsylvania bituminous district. Higher prices reported from Southern and Western coal districts are due to transportation costs or to the purchase of a special grade, or to heavy weight and closeness of weave of jute cloth used. Ten-ounce duck is reported as costing 35c. per square yard in the bituminous districts of Pennsylvania.

The quantity of brattice cloth used per 100,000 tons of coal production varies greatly, the smaller quantities used being reported from non-gaseous mines and the larger quantities from the mines listed as making much gas or as being very gaseous. The number of square yards of brattice cloth used per 100,000 tons of coal produced as reported vary from 245 to 6,060, the more normal requirement for a gaseous mine being 900 to 2,000 yd. The average of nineteen mining companies reporting is 1,697 sq.yd. per 100,000 tons of coal, and the average cost per 100,000 tons, $339.

Based on the above average of 1,697 sq.yd. of cloth used per 100,000 tons of coal production, the total brattice cloth used in the coal mines of the United States annually on a 500,000,000-ton production basis would be about 8,485,000 sq.yd. However, this figure is doubtless much too high, as many non-gaseous mines make little use of brattice cloth.



The width of brattice cloth used depends largely on the thickness of the coal seam. Widths of 36 in., 40 in. and 48 in. are common in low coal; 72-in. cloth is widely used in the thicker coal seams, but 84-in. and 96-in. widths also are reported. The appended table shows the wide variations in the conditions of use of brattice cloth, particularly with respect to quantity, cost and life.

Apparatus That Weighs Furnace Gases, Thus Determining Their Dioxide Percentage

THERE was a time, and not so very long ago, when the greatest asset a fireman in a power-plant boiler room could have was a good strong back. So long as the fireman "kept up steam"—that is, had the safety valve continuously on the verge of popping—little complaint was heard from those who footed the bills even if the amount of coal burned at times seemed large. To many men in former days efficiency meant getting the work done—the fact that it was in many instances accomplished at unnecessary expense made little difference.

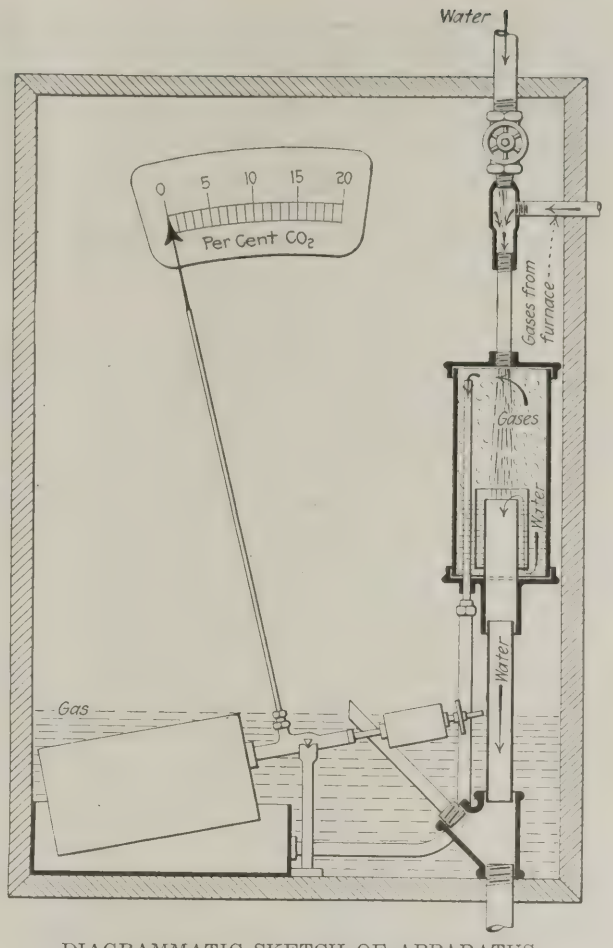
As the years have gone, however, science and research have developed many instruments of which the fireman may avail himself. Today, regardless of whether he stokes with a hand shovel or with an automatic stoker, in order to be successful he must fire quite as much with his head as with his hands. In other words, he must be not only a handler of coal but a combustion expert as well.

Within a boiler furnace combustion is a continuous process carried on under conditions that are somewhat variable. In order that the fireman may conduct the process intelligently it is necessary that he have some

APPARATUS FOR WEIGHING WASTE GASES OF FURNACE

It having been found that with all the efforts at simplification, the analysis of flue gases is slow and somewhat complicated, an instrument has been devised whereby such gases can be weighed continuously as indication of their composition. The result of the weighing is made visible on a scale, so that the fireman can regulate his fire accordingly.

means of knowing exactly what is going on within the furnace. Inasmuch as combustion is a chemical process, visual inspection of the fire is not adequate to the fireman's needs. The appearance of a fire that is burning efficiently may be much the same as that of one that is burning inefficiently.



To indicate the scope and completeness of the reactions taking place within a furnace various pieces of equipment and sets of apparatus have been devised. Probably the best known of these is the Orsat flue-gas analysis equipment, with the manipulation of which most power-plant men are familiar. This apparatus and those of its kind while giving highly accurate and valuable results partakes of the nature of laboratory equipment, being somewhat fragile in construction, intermittent in operation and requiring appreciable skill in its manipulation. In short all "laboratory" apparatus is too delicate and as a rule too complicated for continuous everyday use by the man who maintains the furnace fire.

Instrument Gives Continuous Record

In order to overcome this difficulty and continuously indicate the completeness and efficiency of the combustion in the furnace, and to do it with mechanism the indications of which can be as readily observed as those on the pressure gage, the apparatus shown in the accompanying illustration has been devised by Dr. Zacharias Olsson, now of the Olsson Corporation, of 7 Hanover St., New York City. This device is intended to show continuously the carbon-dioxide content of the flue gas, this being an accurate indication of the efficiency of the combustion process. Its operation does not depend upon the absorption of one chemical substance by another but upon the difference in specific gravity between air and any mixture of nitrogen and carbon dioxide attainable by the combustion of coal in air.

The operation of this device is extremely simple. Water under pressure enters through the pipe at the top of the cabinet at the right-hand side, (see illustrations). After passing the valve by which the rate of flow is controlled it enters the aspirator, which may be seen immediately below the valve. By this aspirator flue gas is drawn continuously through the pipe which may be seen projecting through the right-hand side of the cabinet near the top. Water and gas proceed together to the cylindrical tank plainly visible at the right side of the cabinet and about half way from the top to the bottom. Here the gas disengages from the water and passes down the small pipe that bends to the left and discharges into the shallow box in the lower left-hand corner of the cabinet. The water passes down the larger straight pipe, through a wye fitting and then out of the cabinet to a drain or the sewer.

In the lower portion of the cabinet near the center is a pair of knife edges supporting a tilting lever on one end of which is a rectangular metal box or "float" and on the other an adjustable counterbalance weight. Extending upward from this lever from a point above the knife edges is a long index, or pointer, that sweeps over a suitable scale. This index lever is hollow, has a small hole at its extremity and communicates with the inside of the float in such a manner as will allow the air within the float to expand and contract according to changes in temperature and atmospheric pressure. This arrangement is made in order to prevent errors that otherwise would arise from such changes were the "air float" hermetically sealed against the outside air.

DIAGRAMMATIC SKETCH OF APPARATUS

The balance is adjusted to point at zero when the box is filled with air. The float will rise if a gas heavier than air is introduced. The instrument is calibrated and compensation made for the small percentage of carbon dioxide absorbed by the water operating the suction pump. The "U" tube at the foot of the box is omitted in this diagram as its sole purpose is to afford an indication as to the presence of flue gas in the box and show thereby whether the instrument is working.

Now when the instrument is in operation, the flue gas, after being cooled by the water in the aspirator, is discharged beneath the float and fills the entire lower portion of the cabinet (the door of which is closed) as far up as the end of the slant pipe connected to the branch outlet of the wye. Beyond this it cannot rise because the wye acts as a second aspirator and continuously sucks out the gaseous contents of the cabinet. The cabinet box thus contains two distinct gaseous strata—flue gases in the bottom as far up as the opening of the exhaust pipe and air above this point.

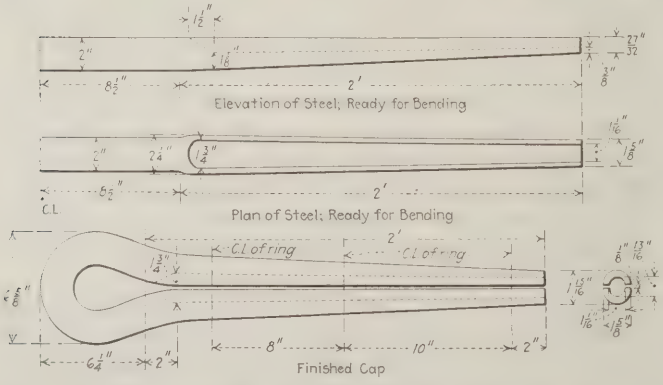
Being delicately counterbalanced the float will be buoyed upward under the action of any gas heavier than air. The specific gravity of flue gas depends directly upon its content of carbon dioxide. Thus the counterbalanced float will assume one elevation when the flue gas contains, say, 5 per cent of carbon dioxide and another when the content is, say, 15 per cent, this percentage being indicated by the position of the index on the scale.

Of course the indication of this instrument lags behind the actual conditions existing within the furnace by an interval equal to the time that it takes the gas to pass from the furnace to the cabinet. This lag varies with the distance traversed but normally ranges from about 15 to 20 seconds. It is incomparably shorter than that which occurs when the percentage is indicated by

a hand-manipulated intermittent chemical equipment. When that is used from 5 to 10 minutes is required to draw, measure and analyze a sample of gas. Placed on the boiler front this instrument gives a continuous accurate indication of the quality of the products of combustion.

Capping Rope Without Using Molten Zinc

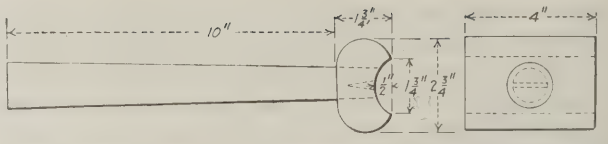
By J. B. de Hart



Nacmine, Alta.

In an article on "Choosing, Lubricating and Attaching Wire Ropes," published in the issue of *Coal Age* of Dec. 14, 1922, J. F. Howe gives the relative strengths of various rope cappings. He does not mention in his list, however, a style of capping much used in Great Britain, Nova Scotia and Alberta, and a description of this may prove of interest. A cap of this type can be, and generally is, made by the mine blacksmith. The following is a description of a cap prepared for use on a 1-in. rope. Other sizes can be made in proportion.

A piece of round mild steel is taken which is 2 in. in diameter and only 40 in. long before being worked. A piece long enough to form an eye of the size required to hold the clevis is marked off at its mid-length. The length in this case will be 17 in. The two ends from the marks outward are drawn down by a hammer to an even taper. A mandrel is made on the lathe of the same size and taper as the rope when bound and ready for capping, and on this the tapered ends are forged so that they will fit the rope. The two halves should fail to come together on the mandrel by about $\frac{1}{8}$-in. The figure shows a plan and elevation of one-half of the cap forged and ready for bending.



Three mild-steel oval disks are made, each about 3 in. thick, and holes are bored in the center of each. These are then forged to go over a mandrel which has been made of the same size and shape as the cap when on the rope or first mandrel. These rings, when hot, should fit tightly at approximately the points shown on the drawing of the finished cap. The outside diameters of the rings should be at all points 4 in. larger than their inside diameters.

The method of attaching the rope to the cap is as follows: Have ready four soft iron rings made of 5-16-in. round iron. The inside diameters of these rings for capping a 1-in. rope are, $1\frac{1}{4}$, $1\frac{3}{4}$, 2, and $2\frac{1}{2}$ in. The rope is then bound tightly for a length of about 4 in. at a point 19 in. from the end of the rope. The strands are

TWO STAGES IN CONSTRUCTION OF ROPE CAP

The two upper illustrations show plan and elevation of one-half of the cap before bending, and the lower illustration shows the cap when bent and the points where the rings are placed on the cap after the rope has been inserted.

HARDWOOD TOOL TO ASSIST IN BINDING ROPE

The tool is placed on the rope and the wire passed twice around the bottom end of the handle. The tool is then passed round and round the rope, the friction between the two turns of the wire and the handle holding the wire tight.

then untwisted back to the wrapping and the wires in each strand also are untwisted. Each wire in each strand is cut off at a different length with a pair of pliers.

Where using 19 in., as in this case, the first wires in each strand would be left uncut, 1 in. would be cut off the next wire, 2 in. off the next, and so on. After cutting, the wires are doubled back along the rope and laid in place, and the core is cut off where the wires are turned back.

Piece of Pipe Aids in Driving Rings to Place

The iron rings are now driven on, the largest one being driven first, and when the smallest ring is about $2\frac{1}{2}$ in. from the end, binding commences. If difficulty is experienced in driving the rings into place, a piece of pipe slightly larger than the inside diameter of the ring can be used, and the pipe driven with a hammer.

The binding is started just far enough from the end so that it will not slip off, and as it gets to the first ring the ring is driven ahead. The binding is carried to a point about 1 in. beyond the end of the cap. The two smallest rings, which will not pass back over the end of the rope, are then cut off with a hammer and chisel, or with a pair of bolt cutters. In order to make the binding tight a tool made of hardwood and shown in the drawing is used.

This tool is placed on the rope and two turns of the wire are taken around the bottom end of the handle. The tool is then passed around and around the rope, the friction between the two turns of wire and the handle holding the wire tight. A new handle can easily be put in when the wires have cut too deeply into the old one.

Rope Bound Either by Iron or Copper Wire

The wire used for binding can be either No. 14 copper wire or No. 12 soft iron wire. The latter is quite satisfactory where there is nothing to cause it to rust or corrode. The first mandrel mentioned above should be of the same shape as the rope with the binding on. The preparation of the rope is now completed and it only remains to put on the cap. The three rings are heated to a dull red heat and the end of the rope is put through them, the smallest one first and the largest one last.

The end of the rope is then laid in position in the cap, and the rings are driven tightly back onto the cap by two men with sledge hammers. This part of the work should be done as quickly as possible so that the rings are hot when driven on. The shrinkage on cooling makes the whole job tight. Finally a steel cone about 3 in. long and tapered from $\frac{3}{8}$ in. to nothing is driven into the end of the core of the rope.

Cappings such as these are used largely in Great Britain, but generally no rings are used, the rope being attached to the cap by rivets through both the cap and the rope. The cap is held tightly by clasps while the work is being riveted. The rivets are of soft iron and

riveted cold. It is doubtful if this method gives as good results as are obtained when the rings are shrunk on.

I have seen a cage weighing 7 tons and containing two cars, each weighing about 1,500 lb., catch in the dogs at the top landing and free itself after the engineman had started to unwind. This cage dropped about 18 ft. and yet the capping, which was such as I have described but placed on a 1⅛-in rope, did not give way in the slightest degree. It may not be as strong as the zinc-filled capping, as stated by Mr. Howe, but I believe a test such as this shows it to be as strong as necessary, if indeed a test is needed when we consider the number of such caps in constant use. With a cap such as this the danger of injuring the wires by pouring molten zinc upon them is avoided.

It would be interesting if Mr. Howe could give the results of comparative tests of a rope carefully capped by this method as against the solid capping. By so doing he would be able to support his statement that the latter is the strongest of all methods of capping a rope.

Utilizes Lighting Circuits for Signaling

From a British Correspondent

CERTAIN mining operations require provisions whereby a person at some distant point can transmit signals to another person operating an engine or motor. Moreover, it may be necessary to record the signals in order to provide a visual indication as well as one that is aural. The working of an engine or motor and gearing often makes much noise, and therefore in the case of a single-stroke bell a heavy blow on the gong is needed if the engineman is to be warned while the machinery is working. Likewise bells or apparatus for making signals require energy for their operation. This energy might be transmitted by a knocker wire, but this form of transmission seldom is satisfactory and therefore will not be considered. Batteries are unsatisfactory for working large bells and quite unreliable for the operation of recording apparatus.

Where alternating current is available, power for signaling may be obtained through a suitable low-voltage transformer. A direct-current supply is less flexible, for the voltage cannot be readily reduced. To put in a small motor-generator set merely to provide power for signaling is not a business proposition. To use a direct current of, say, 100 or 200 volts direct on the coils of a bell or signal indicator also is out of the question, owing to the arcing which occurs when interrupting the circuit. There is, however, a method by which such a voltage can be pressed into service, eliminating the ill effects of self-induction and providing a source of energy much stronger and more reliable than a battery. The arrangement to be described may be used for a variety of purposes which will suggest themselves to resourceful electricians and mechanics.

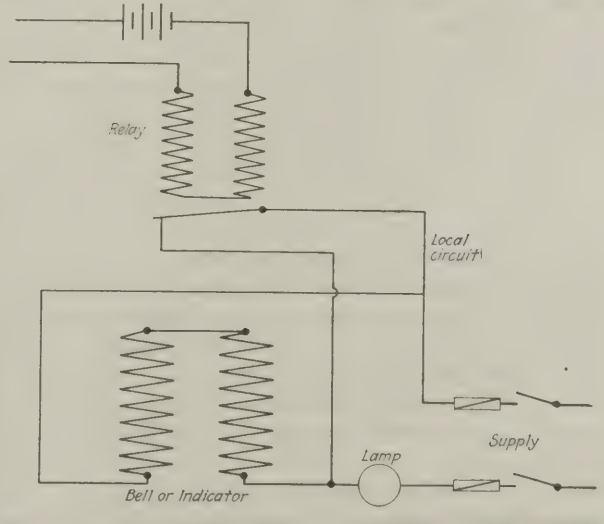
Almost every engineroom at a mine utilizes electricity for lighting. It is a simple matter to connect one of the lamps—say one taking about ½ amp., that is a 32 c.p. carbon lamp on 220 volts—in series with a bell or signal indicator, as shown in Fig. 1. Across the coils of this apparatus is connected a relay which is arranged to close the local circuit when the armature is not under magnetic attraction. Fig. 2 represents a normal relay. The platinum points of the local circuit are indicated at P and the circuit is closed when the armature is drawn up to the magnets, current being fed into the coils through terminals T_2T_4. The armature in its "off" position rests against an insulated stop. Now referring to Fig. 3, it will be observed that P and I are reversed relative to Fig. 2. When the relay armature is in the "off" position the local circuit is closed, and when the armature is drawn up to the magnets the local circuit is interrupted. Thus the relay is, as it were, working the reverse direction to that which is normal.

Referring again to Fig. 1 it will be noticed that the relay diagram there shown corresponds to the arrangement of Fig. 3, where terminals T_1 and T_2 would be connected to the local circuit. It will be seen from the connections that when not in operation the relay short-circuits the coils of the bell or signal indicator. This has no ill effect, owing to the lamp being between the relay and the supply. The lamp merely gives a full light, and may be used as a source of illumination. When the relay is operated by a person sending a signal, its armature is drawn up, and the short-circuit across the bell is opened. The lamp and bell are then in series, the bell coils being strongly energized. Immediately the relay armature is released it again short-circuits the bell, the armature of which falls back into its normal position.

Signal is Visualized by Flashing of Lamp

One or two points should be noticed. In the first place, when no signal is being sent the relay contact is in parallel with the bell coils. The resistance of the platinum points, however, is negligible compared with that of the bell coils. Hence scarcely any current passes through the latter, though there is sufficient to magnetize them slightly. It is necessary, therefore, not to allow the bell or indicator armature to come directly in touch with the magnets when drawn up, otherwise the apparatus will be sluggish in operation. A copper rivet in the armature, projecting about $\frac{1}{16}$ in. will eliminate any tendency of the armature to stick. Due to the relay contacts being in parallel with the bell coils, no sparking occurs at the relay contacts when the circuit is interrupted.

When fitting a relay for this purpose care should be taken to see that the insulation is good between the



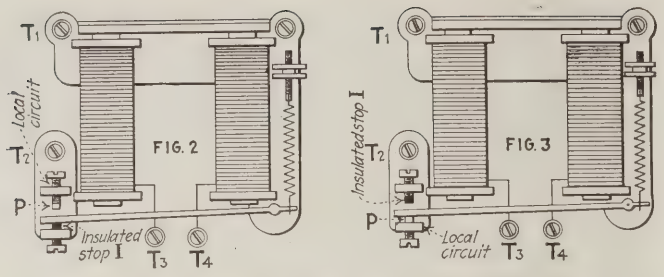


FIG. 1—LOCAL AND SIGNAL CIRCUIT CONNECTIONS

This local and signal circuit avoids the necessity of applying a high voltage to the signal buttons and gives both an aural and visual signal for conditions where there may at times be considerable noise.

FIGS. 2 AND 3—STANDARD AND ADAPTED RELAY

The standard relay may readily be adapted so that the lamp will light brightly when shunted on the bell coils and go out when in series with the bell coils, thus visualizing the signals.

relay coils and the local circuit, otherwise there will be leakage to the signaling circuit. It hardly need be added that the arrangement described should not be employed where gas is present and may be ignited. There are numerous applications, however, both in and out of a mine. The advantages may be summarized as follows: (1) No batteries have to be maintained; (2) the bell or indicator coils are strongly energized; (3) the lamp which is in series with the coils may be utilized for illumination; (4) the relay contacts do not spark and (5) no short-circuit can be formed by a failure of the bell coils, owing to the lamp being in series. The arrangement obviously is unsuitable for connecting to a trembler bell.

Life and Testing of Hoist Rope Discussed

SOCKETING of ropes, injuries in manufacture, fatigue and the possibility of testing a rope magnetically were discussed at length in the course of the joint session of the American Institute of Mining and Metallurgical Engineers and the National Safety Council during the New York meeting of the former. Strange to say, question was raised whether the strongest socket is necessarily the best.

Mr. Lindquist, an elevator rope specialist and chief engineer of the Otis Elevator Co., said that there was no one best socketing method, for the socket which might resist tension best might be so rigid that the rope would break from torsion, whipping and vibration. By whipping he had reference to the movement in the slack rope and by vibration to the action of a rope under strain. The more definite the point of rigidity the more certain the injury to the rope. It would serve but little to have a socket of unequalled efficiency if in attaining it the end of the rope was so rigid that the wires were broken. With hydraulic elevators it had been found that swiveling sockets increased life, but ball-bearing sockets are better. The socket should be light, however, or trouble will result from vibration.

Fatigue, said Mr. Lindquist, attacks the outer shell of the wire first and when the exterior cracks, failure results from the extension of these cracks. In discussing the elastic limit, dependence should not be placed on that obtained with one application of load. That is not the true elastic limit of the material. Some alloy steels seem built to mislead the purchaser; they show a high elastic limit on the first application of stress but an unduly low one where the stress is many times repeated.

Cables, he added, were uncertain quantities. Sometimes when a cable of a certain type and make has proved lacking in life, another one of identically the same type and make has been used in its replacement and proved most successful in standing up under the same working conditions. This is a matter requiring careful investigation. In making these suggestions Mr. Lindquist added that nicking in manufacture and improper stranding explained the uncertainty. When nicked a wire is prevented from sliding to accommodate itself to changing conditions. Mr. Lindquist said that the wires of a soft rope nick readily and may break without warning.

Strange to say, it is injurious to a rope to let it run under light load. It does better, said Mr. Lindquist, when the load never changes. Apparently the wires in the rope under light load have a different bearing surface under which new defects may develop.

R. L. Sanford, an expert of the Bureau of Standards, read a paper describing the line of attack by which it was hoped to find a way of testing hoisting rope in place by magnetic effects. With the aid of a magnetic field it has been possible to discover hidden defects in rails and rifle barrels. B. F. Tillson has been trying for many years to get an appropriation from the government for an inquiry into the possibility of testing wire ropes in this manner. The Bureau of Standards at last has received an appropriation. Mr. Sanford does not promise success in this investigation. There are difficulties in the way, as Mr. Lindquist sympathetically pointed out.

For instance, there may be magnet effects, said Mr. Lindquist, that have nothing to do with the mechanical condition of the rope, for the rope may itself have been magnetized in service, and this magnetization may be so pronounced that the galvanometer would fail to record the effect of passing a break in a wire or wires. Of course, we can resort to the demagnetization of the rope, but it is impossible to demagnetize a rope completely. Fortunately, Mr. Lindquist added, fatigue is not equal over the cross-section of a wire. A wire does not weaken all over at one time but cracks first form on its surface. These the galvanometer should be cognizant of, provided the rope is not too greatly magnetized before the test is made. It seemed agreed that it might be possible to pass the coil by which the test would be made over any socket on the rope. The coil would not have to fit the periphery closely.

STUDY OF THE CLEANING OF COALS of the Pacific Northwest and Alaska conducted during the past few years will be continued at Seattle, Wash., by the U. S. Bureau of Mines. The objects of this work are to study the defects of the present washeries and to determine the washability of coals not being washed at the present time. Large-size samples will be taken at the mine or washery and brought to the coal-washing laboratory for testing. Emphasis will be laid upon the use of tables in coal washing work. The application of froth flotation to the treatment of washery waste or coals difficult to wash will be studied.

A CONTINUING STUDY is being made by the field engineers of the U. S. Bureau of Mines relative to the methods of mining coal under the various conditions in which it is found, for the purpose of determining and improving if possible the percentage of extraction, together with the degree of safety attained and possible. When a sufficient number of mines has been investigated in any particular coal bed, it is planned to summarize the methods of mining in a Bureau publication, calling attention to any unnecessary loss of coal in the different methods of mining operations.

Storing Coal on the Ground and Reclaiming It with the Aid of a Cable Drag Scraper

Scraper Working Over Top of Pile Can Unload or Load Anywhere, an Advantage in Fire Control—Coal Sizes Are Mixed, Making Fire Less Likely—Handles Coal Rapidly and Cheaply

By H. V. Schiefer
Cleveland, Ohio

THE usual methods of mechanically storing coal consist of portable, or bucket, conveyors for use in small storage piles; and grab buckets with cars, grab buckets with conveyors, fixed-conveyor systems and cable drag scrapers for storage piles of large capacity. The portable conveying belt is loaded by hand. In consequence its capacity is limited by the quantity that can be shoveled onto it per hour. When the lower end of the conveyor is run into a pit beneath the railroad track and is fed by a mechanical feeder, it then becomes a fixed conveyor system and though it has a greater hourly capacity than other storage plants it is less flexible than when free to move to any point.

Fixed conveyor systems were much in vogue for coal storage from about 1910 to 1916 or 1917. These consisted usually of a V-bucket elevator conveyor, which received coal from a hopper beneath the track, elevated it about 20 ft., then ran horizontally, dropping the coal through gates to storage. The length of the conveyor was made to suit the quantity of coal to be stored. The return run of this same conveyor operated in a tunnel beneath the coal pile.

For the average plant this was one of the best of storage methods. Its chief defect was that only half the coal could be reclaimed from storage without recourse to other handling. This same objection applies to monorail or other straight-line storage systems, which pile the material in a long triangular shaped pile, half the material being out of reach of the reclaiming bucket.

Systems embodying the grab bucket and the conveyor consist either of locomotive cranes and reclaiming belt conveyors or of bridge cranes operating a grab bucket and provided with a similar conveying unit. Conveyors are used in conjunction with cranes because the latter cannot advantageously pick up a grabload of coal and travel with it.

A method of storing coal with unusual possibilities is the cable drag scraper system developed by the R. H. Beaumont Co., 319 Arch St., Philadelphia, Pa. This method of operation is being installed at the mines of the King Harlan Coal Co., at Kilday, Ky. It will handle 275 tons per hour. Another installation is in use at the mines of the Westmoreland Coal Co., Irwin, Pa. It consists of a steel scraper attached to an endless steel cable, which latter is operated by a double-drum winding machine and runs out across the field to steel posts planted around the storage area.

FIG. 1—TWO-TON SCRAPER UNLOADING COAL

In the rear will be noted the steel posts to which the pulley is attached when coal is to be unloaded or reclaimed between any one pair of posts and the initial coal pile. It will be seen that the sizes are not appreciably segregated when being dumped. With such a large scraper an unusually large tonnage can be handled.

The scraper is dragged back and forth over the coal, it being quickly detachable so that it can be turned around when the coal has to be reclaimed. The size of the storage pile is limited by the area outlined by the steel posts and the depth of the storage. More capacity can be obtained merely by moving back the steel posts. The area of the pile may be made of any shape, nor is it by any means necessary that it be level. The coal can be stored or reclaimed from any part of the area, all the preparation necessary being to move the tail blocks from one post to another.

FIG. 2—TWENTY THOUSAND TONS OF STORAGE

The two steel posts to the right in the background not being in a heavily filled area exhibit the concrete foundations which provide the necessary stability. The scraper is in the left background. This is rather a "stock yard" than a "stock pile," so moderate is the storage depth and so level the surface. These conditions make spontaneous combustion less likely. This shows a larger area of the same pile as that shown in Fig. 1.

The scraper moves out its coal from an initial pile, which may be formed by dropping coal from a tipple or from a chain-and-bucket elevator or by some other means. In reclaiming, coal is pulled back to the starting point and rehandled to the cars by the equipment that built the initial pile.

The cable drag scraper system of storing coal is controlled by an operative in an elevated cabin at the side of the storage field. The machinery house can be set anywhere. Should the coal heat, the operative can make the scraper attack the heated area and turn over the coal. On account of his remote position he is not troubled by smoke or fumes. When a steam or electric crane attempts to attack a fire in the heart of a slack pile it frequently has to dig out a large body of coal

FIG. 3—AN 8,000-TON YARD FOR AN OHIO FACTORY
On the right is the elevator from which is formed the mother pile from which the yard is filled. This elevator receives its coal from a hopper below the railroad tracks which is fed either from the yard or the railroad cars and delivers coal either to the railroad cars or the yard. It will be seen at what a high point the scraper is delivering, demonstrating that where the yard is not as level as this one the coal can nevertheless be satisfactorily placed and reclaimed.

that is not in the least heated in order to reach that which is burning or nearly burning beyond.

Another advantage of the scraper method of placing the coal is that it does not store it with the fine coal on top and the coarse coal below. When piles are placed by a grab bucket the coal falls in a pile and the larger lumps roll down to the bottom, so that if proper care is not taken the base of the storage consists of coarse coal and the top coal is fine. With the scraper method the coal is mixed thoroughly and is compressed so closely that air cannot enter the pile.

Those who have used this system of storing declare that they have had surface fires but no fires in the center of the pile. However, should such a fire occur at a point remote from the edges of the pile the scraper would uncover it without difficulty. Owing to the ease with which storage piles covering large areas may be made with scraper equipment if available ground permits, the coal need not be stored to any excessive depth. In consequence fires are less likely than with some other methods of storage.

The capacity of such a drag scraper is high, running from 50 to 600 tons per hour, dependent on the size of the scraper used and the length of the haul.

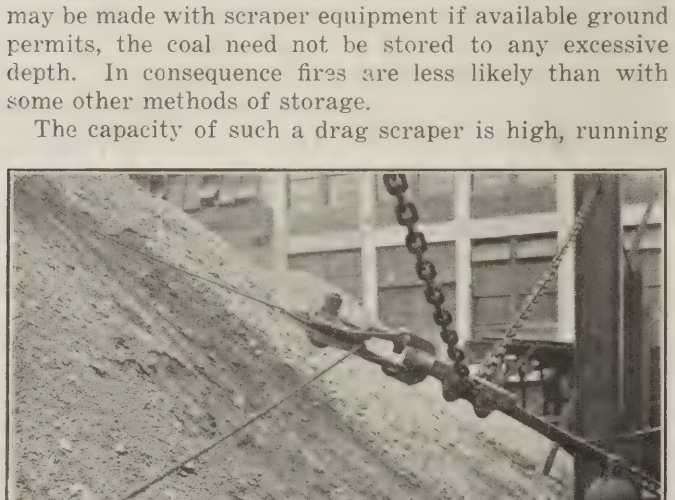

FIG. 4—METHOD OF SUSPENDING TAIL PULLEY
A chain is bolted between two of the posts, in which holes are provided for attachment. From the chain is hung the counterweighted pulley arm.

Many coal-storage equipments are extremely economical in operation. If they worked night and day and always at top capacity they would do the work at a negligible figure but when they work intermittently the interest and maintenance charges more than eliminate all the profit. Others have in addition high operating charges. For instance, an expert operator commanding a high wage must be employed to run a crane, whereas the drag scraper can be handled by a man without training or experience.

The first cost of a drag-scraper system is low and the maintenance cost is inconsiderable, for when the machine is idle the rope is wound on the drums and the scraper may be stored anywhere under cover, the only parts exposed to the weather being the machinery house and back posts. As about 90 per cent of the moving parts are of steel the wear and tear is not excessive. The largest part of the investment is in steel and concrete, which depreciate slowly. The salvage value is high, for the plant is quite mobile. It will fit any storage area. The cable can be used as a car puller by simply extending the countershaft and adding a winch head and outboard bearing. A clutch is provided to throw in the car puller when required.

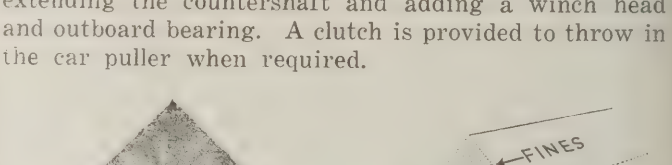

FIG. 5—ILLUSTRATING EVIL OF CONICAL PILING
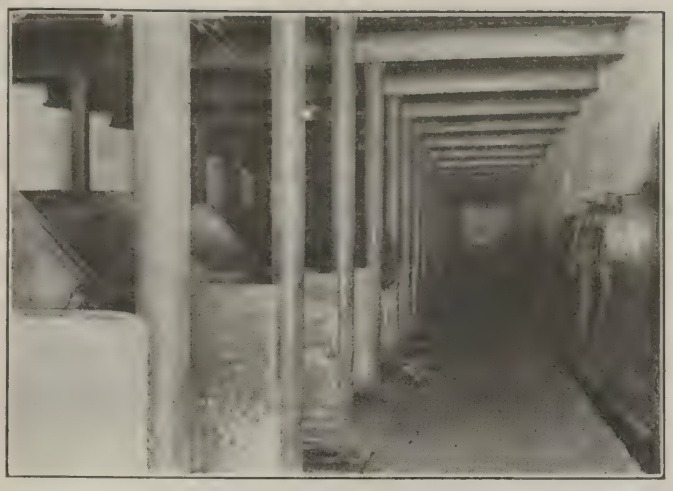
In the left-hand illustration a big pile of coal has been made by a grab bucket which has dumped coal repeatedly from one point. The larger lumps have run down the side of the pile and so a body of fine coal rests on a mass of larger coal which gets progressively coarse toward the bottom. The air can circulate freely through the large coal and feed the finer coal with air should the pile begin to heat. This ventilation also favors the initial heating, for while it causes incipient combustion, the fine coal delays the escape of heat upward. The figure on the right shows the same effect obtained by a long continuous pile of pyramid shape.

$12,000,000 Power Plant Will Mean Much To Northern Colorado Coal Fields

ERECTION of a huge steam-electric power plant on Boulder Lake four miles east of Boulder, Colo., by the Doherty interests, the plan for which was announced recently, may mean a good deal to the coal fields of northern Colorado. A ready source of electric power will be available for mining use and a ready market will be at hand for a considerable volume of lignite slack such as now burdens practically every northern operation. The plant, estimated to cost $12,000,000 and to be built by the Cities Service Co., to serve the Denver Gas & Electric Light Co. and the Western Light & Power Co. may be of 100,000-kw. capacity. The first unit, a 20,000 turbo-generator to cost $4,000,000, may be in service by March, 1924. The boiler room for this is expected to consume 125,000 tons of coal annually.

From an engineering viewpoint, the plant is of much interest. It is unusual to locate such large plants on artificial sites, even large artificial lakes, as this is. Rivers or other large streams are more common. However, their absence made it necessary to select this site, a lake the surface of which will be increased to 380 acres, and volume of water impounded to 280,000,000 cu.ft. Further, steam is to be used at 375 lb. pressure and 200 deg. superheat.

Structural Details of Underground Stable

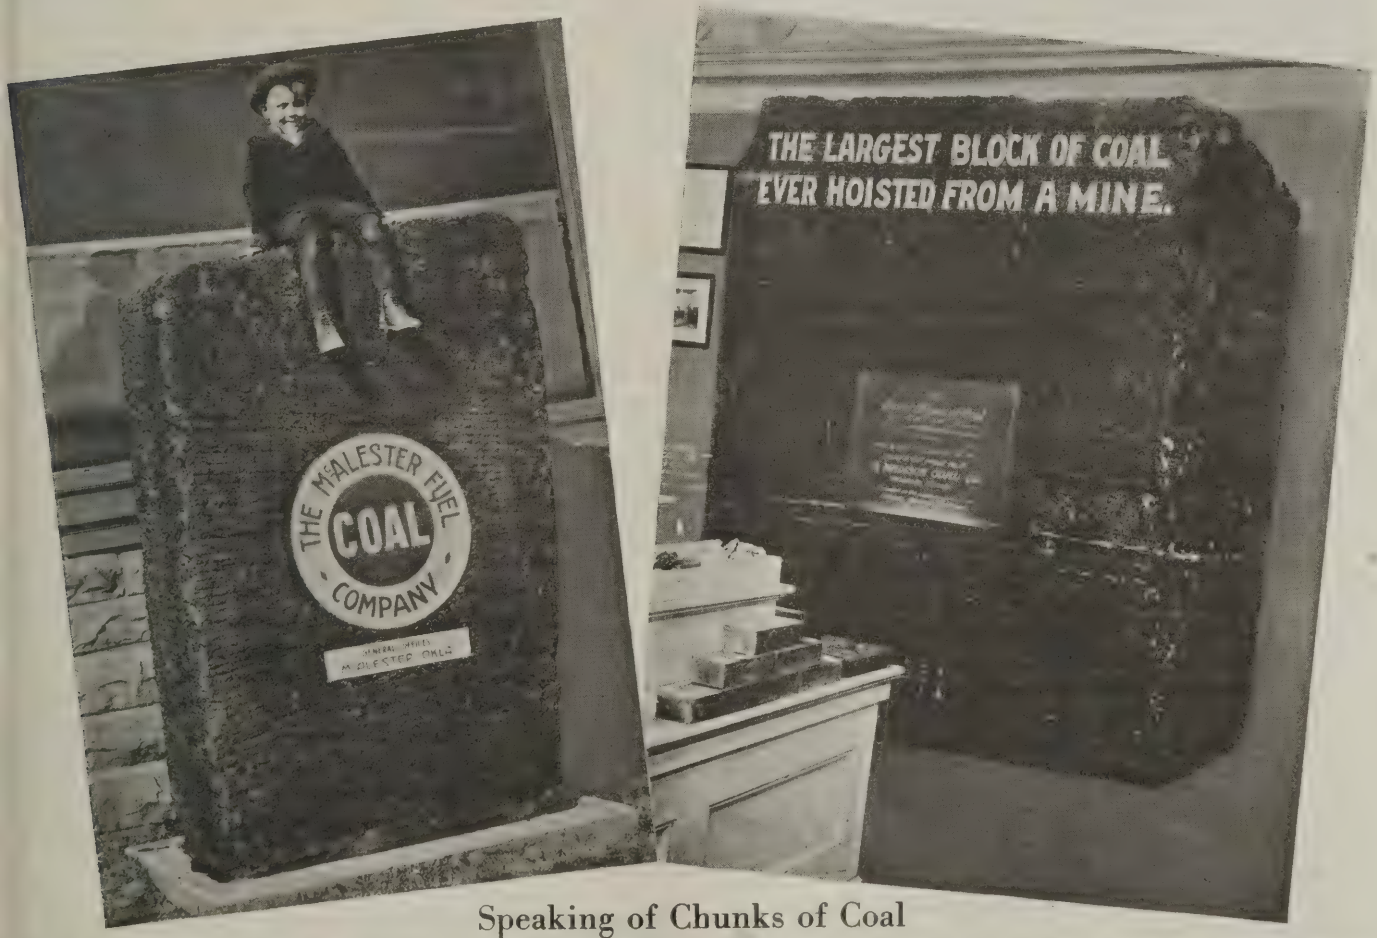


By Alphonse F. Brosky*
Pittsburgh, Pa.

SOME of the mines working the Pittsburgh and other seams still use horses for gathering operations. Gathering locomotives have not entirely supplanted animal haulage, for under certain conditions the latter is more economical than the former. More horses than gathering locomotives are used in the Criterion mine of the Westmoreland Coal Co., at Rillton, Pa., and accordingly a stable has to be maintained. In this mine the stable, which is quite modern, is placed underground.

Strangely enough, though members of humane societies object to the keeping of animals underground, mining men find that the veterinarian has fewer calls to underground stables than to those on the surface, especially where the stable is close to the entrance to the mine. So located the stable is less injurious to the health of the men in the mine and to the animals in the stable. At the Criterion mine the mules are stabled in a chamber 425 ft. from the main bottom of the hoisting shaft. It is ventilated by a split off the main entry intake, which passes through the stable to the return airway and thence to the upcast 300 ft. away.

The stable is 145 ft. long and 21 ft. wide, being furnished with twenty-two stalls of concrete, the floors of which are of wood. The ceiling is supported by 12-in. beams on 6-ft. centers which rest upon 13-in. side walls of brick and are further supported by two 6-in. pipes filled with concrete. Above the beams are 20-lb. rails used as stringers and between these rough bricks are laid, a construction often used for the roofing of overcasts.



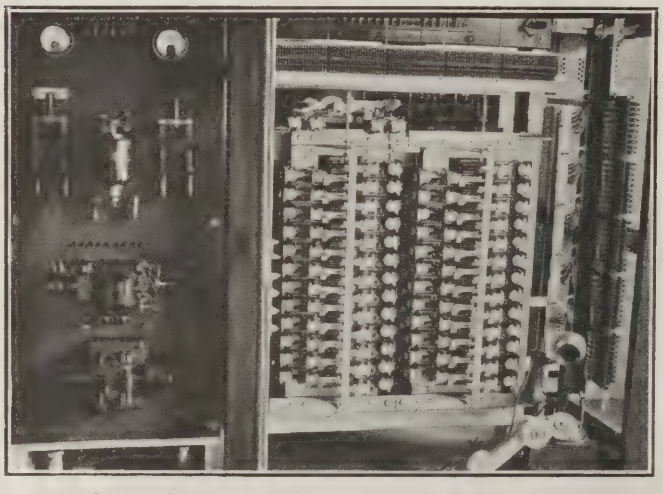
*Assistant editor, *Coal Age*.

STABLE ENTIRELY FIREPROOF EXCEPT STALL FLOORS

A really modern stable no longer is a measurable fire risk, for the stall floors are not likely to catch fire and no hay or bedding is stored in or near the stable. Should the bedding catch fire, the flame would be confined to the particular stall in which the blaze occurred.

Speaking of Chunks of Coal

Here is a 7,600-lb. lump of McAlester coal from the Homer Mine of the Osage Coal Mining Co., near McAlester, Okla. It measures 6 ft. 6 in. x 4 ft. 6 in. x 3 ft. 6 in. This chunk, extracted for the Rotary convention in Wichita, Kan., in 1921, was never shipped and now stands in front of the McAlester Fuel Co.'s office in McAlester and has stood there for some time without suffering from the weather. Its "biggest" claim is that it is the biggest chunk ever taken from a 4-ft. seam.



"The Cyclops of them all" is what A. J. Moorshead, president of the Madison Coal Corporation, calls this old timer exhibited at the St. Louis World's Fair in 1904. It weighed 14 tons and has a legitimate claim to the title of "biggest lump ever mined." Expert pick miners extracted it from the Divernon mine, near Springfield, Ill., at a spot close to the shaft bottom where office room was needed. The block measured 6 ft. x 7 ft. x 8 ft. 2 in. The cage was dismantled to get this monster up the 335-ft. shaft.

Raleigh Coal Co. Keeps in Touch with Key Workmen by Automatic Telephones

By A. F. Brosky*
Pittsburgh, Pa.

THE American Telephone & Telegraph Co. and other telephone companies already have come to a realization of the many advantages derived from the installation of automatic telephone service and now feel assured that millions of dollars would be saved if community telephone services were made automatic, and work has already been commenced on a large scale in the bigger cities to that end, some units being already in operation.

If the practicability of the machine-switching telephone system is so well established that the public-utility companies do not hesitate to install it on a large scale, why is it not even more ideally adapted to the conditions in the rural or the isolated districts in the coal fields, where small independent systems often are installed and operated by the coal companies? An electrical engineer who worked on the automatic telephone several years ago assured me that the new system

AUTOMATIC SWITCHBOARD OF RALEIGH COAL CO.

Mining villages usually are a little way from the mine and stretch out over a large area. If anything goes wrong when the day's work is over it is difficult to get the right man promptly for the particular repair job unless a telephone is provided, and then it should be a self-switching telephone, that will not wake up every key workman and boss on the job just when he is taking the sleep that will fortify him for his next day's work.

is far superior to the old, even where as few as fifty telephones are installed.

Wherever the automatic telephone system has been used in factories, warehouses and offices of large concerns it has operated successfully. For this reason it might be well for coal companies likewise to consider whether the automatic telephone could be applied satisfactorily to their needs either at a single mine plant or at a group of plants, including mining towns also.

Four years ago the Raleigh Coal & Coke Co. installed an automatic system of fifty telephones in the town of Raleigh, W. Va. The system co-ordinates the work of the several operating departments and provides a sure means of communication with those men whose services might be required at inopportune times during the twenty-four hours of the day. And this is accomplished without resorting to manual assistance or to a system of long and short rings whereby half a score of families are awakened in the dead of night in order to establish communication with some one somnolent individual. Direct signaling and connection are made by the caller to the party called.

Besides the telephones in the general offices and other company buildings, there are telephones in the homes of the superintendents, foremen and other bosses and company officials. The residences of the master mechanic, electricians, carpenters and others whose services are indispensable at unexpected times are similarly equipped.

The system cannot be used underground because of grounding. Consequently the automatic telephone service extends no further than to the office of the weighmaster on the tipple. All communication from the outside to the inside is delivered to the weighmaster, who relays it over the underground telephone system.

At Raleigh, W. Va., the system used is that of the Chicago Automatic Telephone Co., whose rights have been acquired by the Western Electric Co. From the original Strouger system two different types of equipment have been evolved. The type that will be used in the large cities is called the panel system and that which will be introduced into the self-contained communities is known as the step-by-step system. We are told that the machine-switching telephone system owes its success to the most complex electrically operated mechanism in the world. Primarily it is based upon a system of relays. During the process of completing a call in the large system it is said that about 750 contacts are made in a period of 7 seconds.

The machine-switching board which maneuvers the calls from 50 telephones in Raleigh appears in the illustration. The lines end on small terminals which are mounted vertically on a frame as shown. When the caller lifts his receiver an electrical condition is created which causes a line finder to elevate vertically to the line of the caller, where it stops. The caller then hears a humming noise which is a signal for him to dial the number of the party called. The numerals dialed by the caller set up electrical impulses operating an electrical device called the sender, which is the brains of the system.

The sender receives the call number dialed by the caller and directs subsequent operations of the apparatus, thus establishing a connection with the line of the party called. If that line is busy the caller is informed of that fact by a buzzing sound which is distinctive and differs from the ring of the call bell.

The potential of sending is 52 volts direct current, while that of receiving is 84 volts alternating current. A storage or secondary battery in the circuit is automatically charged through the agency of a motor-generator set in the circuit and furnishes the direct current for the transmission of the voice.

When the potential of the battery falls below 46 volts a relay makes contact and closes a circuit to an automatic starter in the circuit of the battery and generating unit. After the potential of the battery is raised to 52 volts, which is the maximum voltage, the charging is automatically cut out from the battery through a breaker.

---

*Assistant editor, *Coal Age*.

"Reports of Investigations issued during 1922," Serial 2440, recently issued by the Bureau of Mines, lists a number of reports relating to the technology of solid and liquid fuels. The subjects treated include the use of bituminous coal in house-heating furnaces, fuel economy from oil plant equipment, determination of sediment in fuel oil, steaming tests of Alaskan lignite, smoke prevention, Trent amalgam, etc.

Effects of Ruhr Occupation Reflected in Curtailed Production of Coal

Although railway strikes, resulting in congestion and disorganization of the transportation system, have practically divided the Ruhr district into a number of local districts without communication with each other and almost completely isolated from the outside world, *Coal Age* is in receipt of information showing that coal production in the Ruhr which in the larger part of January was forced by all means available, had during the last week of that month decreased to an estimated tonnage of 270,000 per day, as compared with a normal daily capacity of 350,000 tons. Actual shipments after the blockade was put in force were for delivery inside the Ruhr district. Total shipments, which up to Jan. 20 averaged about 20,000 carloads of ten tons each per day, had on Jan. 30 decreased to 9,500 carloads, on Feb. 2 to 2,000 carloads and on Feb. 4 to 1,200 carloads, equalling 12,000 tons, or about 3 per cent of normal output.

As the accumulation of reserves within a few days reached the limit of available space, production was reduced early in February to the limited possibility of shipments and to the demand of coking plants, which at the beginning of the month were still in full operation. No discharge of coal miners on a large scale had taken place in the Ruhr district up to the first part of February. When not engaged in the production of coal they were used in improvement and development work.

There was no actual pinch up to the early part of February in the unoccupied parts of Germany occasioned by a lack of coal. The railways were provided with from six to seven weeks' reserve stocks and gas and electric plants and other large consumers had supplies sufficient for approximately one month.

According to the statements of the Coal Commissary and the National Ministry of Economics import licenses granted during January were considerably less than in October and November. The drop in the value of the mark widened the margin between German and British coal prices. The last increase at that time was 77 per cent, bringing the price of Ruhr fat run of mine to 68,411 marks per ton, which at the rate of exchange prevailing at the beginning of February equalled 7 gold marks.

Production in those mines situated near the borders of the Ruhr mining district, but outside of the cordon drawn, was continued under heavy pressure up to the first part of February. At that time it was considered unlikely in authoritative German circles that those mines would be included in the occupied zone.

The German Coal Commission informed a Reichstag committee March 9 that the country's coal supply was on the whole satisfactory. Thanks to large supplies of reparations fuel which were diverted to unoccupied Germany instead of to France and Belgium during the first few weeks of the occupation, and to large importations of British coal last year, the commission said, the railways, public utilities and private consumers were well taken care of.

Prior to the occupation Ruhr coal production was distributed as follows: Entente tribute, 20 per cent; occupied Germany and local consumption, 38 per cent, and the interior of Germany, 42 per cent. Considering the outlying mines left out from the occupation, the coal deficit resulting from the Ruhr blockade was estimated at about 2,700,000 tons per month, or about one-third of the output, and the shortage of coke was more than 1,000,000 tons per month. The increase in production in the remaining coal fields—Upper and Lower Silesia and Saxony—expected from overtime shifts was estimated by the Coal Commissary at about 500,000 tons per month, although it is thought it will be nearer 300,000 tons. In this connection it may be mentioned that a coal-dust explosion in one of the largest Upper Silesian mines has put this mine, which produced approximately 500,000 tons per year, out of operation for some time. The production of the Upper and Lower Silesian and Saxon fields in January was about 1,700,000 tons.

Germany is practically independent of the brown coal produced in the occupied mine fields. The latter contributed to the German interior only 5 per cent of their production of brown coal and 5 per cent of the brown coal briquets produced. It is intended to operate the brown-coal mines in central Germany on Sunday, which with the three shifts they are now working probably will increase their present production of 8,000,000 tons per month by about 1,300,000 tons. The glass industry is the only industry using brown coal to a large extent.

COAL PILES AT RECKLINGHAUSEN, IN THE RUHR VALLEY

Here are piles of precious coal that France achingly needs, and that she plans to get, fair means or foul. However, until she can get trains and workers she is helpless. Recklinghausen is now occupied by the French troops.—*Photo Keystone View Co.*

German Government Provides Foreign Funds at Low Rates to Import Coal

While all the world was wondering how Germany could hold out against the Ruhr blockade, which deprives the country of half of its coal supply and four-fifths of its iron and steel resources, the German Government threw large sums of foreign money upon the money market to improve the value of the mark in exchange. This money was taken from funds accumulated from export proceeds for the avowed purpose of reparation payments. It will be remembered that every exporter has to deliver to the government about one-fourth part of the foreign money realized by sales abroad. The government is a coal consumer only as far as the state railways and a few state works are concerned. The funds in hand exceed by far the government's own requirements.

The move to give away these funds at comparatively low rates must be interpreted as an attempt to provide industry with the necessary means for replacing the Ruhr supply of basic materials through purchases abroad. Coincidental with this move coal prices have been increased by about 80 per cent, bringing the standard grade of Ruhr fat run of mine up to 123,356 marks per ton and all other grades in proportion. The government's manipulation of the mark has raised these prices above the level of British prices. This doubtless is intended as an inducement to private consumers to cover their requirements toward coming emergencies and to do it without any sacrifice to themselves. It is the first time since the end of the war that German coal prices have been raised above world market prices.

The usual monthly report of production for January, originating from the Coal Syndicate, has come out, but it contains no figures. The January production of coal in Upper Silesia was 787,000 tons in 25 days against 733,690 tons in 22 days in December. This drop is due chiefly to accidents in two mines. In the other mining districts, those of Lower Silesia and Saxony, production has remained at the level of the preceding two months. In Lower Silesia the miners have agreed to overtime work in the shape of an additional hour every day. In the Saxon mines it has been decided to provide work for discharged Ruhr miners. Brown-coal production in central Germany in January showed a slight decline. The efforts made to increase coal production in the interior of Germany up to the middle of February had shown no material result.

Extraction of Room Pillars in Working the Miller Seam

Conditions in Miller Seam Extremely Bad—Experience in Working Under 400-Ft. Cover—Constant Need of Taking Up Bottom

HAVING had a considerable amount of experience in the matter of extracting pillars under varying conditions in different seams, I was deeply interested in reading the inquiry of Robert Holt, which appeared in *Coal Age*, Feb. 1, p. 226, regarding the difficulties experienced in the extraction of pillars in the Miller or "B" seam.

My knowledge of the Miller seam leads me to say that conditions in that seam are the worst I have ever experienced in respect to the tendency to squeeze or creep. The description given by Mr. Holt regarding the conditions in his locality are typical of the conditions existing elsewhere in the working of that seam.

Rooms 24 Ft. Wide Driven on 60-Ft. Centers

For his information, allow me to give a little of my own experience in working the Miller seam under a cover of about 400 ft. The face headings were driven to the full dip of the seam, which was about 3½ per cent. The butts were turned to the right and left of the face headings. The rooms were turned off the butts on the full pitch of the seam, or parallel to the face headings. The rooms were driven 24 ft. wide, on 60 ft. centers.

The face headings were driven narrow, 8 ft. wide, while the butts were made wide enough to gob the rock, the back heading being 12 ft. wide. It was the purpose to drive the rooms to a depth of 275 ft., leaving a 50-ft. barrier pillar for the protection of the butt headings. In one instance in particular, owing to extraordinary roof trouble, the turning of rooms was started somewhere near the middle of the first pair of butts, which did not prove a success.

We hoped to start the break in the center and pull the pillars back quickly. But, before the rooms had advanced more than half way up the pitch it was necessary to start to take up bottom from the switch. Before the rooms were finished the bottom on the gob side was nearly up to the roof, in spite of the fact that we narrowed the rooms to a width of 18 ft.

In that case when the work of drawing back the pillars was commenced I started two new room necks. We drove these 12 ft. wide for a distance of 50 ft. before beginning to widen out the rooms. However, even then we had to come back to the heading and take up bottom to keep the road open. This shows the conditions that exist in the Miller seam.

To my mind, the only way to work this seam successfully is to drive the rooms 5 or 6 yd. in width and on centers up to 100 ft., so as to provide ample pillars for the support of the roof in the first working. The larger the pillars the better results will be obtained and there will be less danger of squeeze such as I have mentioned was our experience. I would suggest driving the rooms in groups of five. When these rooms have reached the limit, cut through the pillar from the last room to the adjoining one outby. Make this cut, say, the full width of the room and then use judgment in continuing to draw back the pillar.

Advantage in Leaving Wide Pillars

The work of drawing back the other pillars in these five rooms should proceed in regular order, taking care to keep each successive pillar at least one cut behind the preceding one. In this manner all the pillars in the five rooms should be drawn back to the entry stumps, keeping the line of pillarwork as straight as possible. Attention to this point has often been drawn in *Coal Age*.

The advantage of driving rooms with wide pillars between them is quickly seen in the work of robbing. When a few cuts have been made in the pillars in the manner just described a break will have started and there is plenty of room for a good cave, which will greatly relieve the pressure on the pillars and avoid the possibility of squeeze blocking the roads. Where the conditions require pillars, say 100 ft. wide, it will be better to haul the coal both ways on the face of the pillar. In that case, it will be found of great advantage to maintain the tracks in each room until the adjoining pillar is finished.

Narrow Pillars Sure to Develop Squeeze

It must be remembered that one disadvantage of leaving narrow pillars is that a sufficient area is not provided to afford a good cave. As a consequence the pillar coal is much crushed and it is difficult to keep the roads open by reason of squeeze. In working back wide pillars it will generally be found to pay to lay a curved track at the end of the pillar. This curve can be moved forward as the work advances and another cut is made through the pillar.

Allow me to say one cannot trifle with the work of drawing pillars in the Miller seam. I have seen a small stump left behind when taking out heading stumps and it cost the company hundreds of dollars. My advice is never leave a stump in, no matter how small it may be. It will give trouble later. If it cannot be removed with the pick shoot it out.

Under the best conditions in the Miller seam there is constant need of taking up bottom. The reason is, I believe, that the seam is overlaid with a comparatively thin slate roof, say 10 ft. thick, above which is a thick bed of sandstone that is hard to break. To make matters worse the floor of the seam is a fireclay nature that appears to slack like lime.

THOMAS HOGARTH.

Coal Brokerage

Sweeping statement made regarding the work of coal brokers. All brokers not "parasites." Majority fill economic positions in the coal trade.

MY ATTENTION was recently drawn to the statement of a correspondent that appeared in *Coal Age*, Feb. 22, p. 339, and is certainly misrepresentative of a large class of business connected with the selling and distribution of coal today.

Under the heading "Handling of Shipments of Coal Through Brokers," which he styles as "Harmful to the Industry," the correspondent makes the very sweeping statement that coal brokers are "parasites." To say that this statement is unfair to brokers as a whole will not be denied by those familiar with the coal business in respect to marketing the product.

While there is no doubt that some brokers are parasites to the coal industry, the large majority of this class are fulfilling a truly economic condition and one that is fully justified.

It is well known that the legitimate coal broker by his acquaintance with the avenues of trade is relieving the producer of the necessity of establishing and maintaining in many cases, sales organizations to bring him into touch with the ultimate consumer, if the mines he operates are to be kept running continuously.

In many cases the coal broker is in a position to help the operator in financing his payroll, which is not the least portion of his service. As I have just stated, however, the service rendered by the broker in finding a market for the coal mined surely justifies his existence. Had this correspondent followed out his logic to its rightful conclusion he might have said that the operators should retail their own coal in order to obviate the parasitic profits accruing to the retail distributor.

Dayton, Ohio. M. R. ATKINSON.

Lengthening of Lamp Flame in Gas

Theory of lengthening of lamp flame due to decrease of pressure absurd—Flame lengthened in effort to reach air for its consumption.

WITH much surprise and interest I read the inquiry of a correspondent who set forth a new theory in regard to the lengthening of the lamp flame in a safety lamp exposed to gas, and asked to have the views of others in regard to its correctness. This inquiry, together with the reply of the editor, appeared in *Coal Age*, Jan. 25, p. 186, and was entitled "Action of Safety Lamp Flame in Firedamp Mixture."

If I understand rightly, the theory proposed by this correspondent was that the lengthening of a lamp flame exposed to a body of firedamp was the natural result of a decreased pressure within the lamp, owing to the presence of the gas (methane).

The argument was advanced that both the heating of the air in the lamp chimney and the presence of the lighter gas had the effect of increasing the upward pressure and decreasing the downward pressure within the lamp. It was claimed that the result was to increase the velocity of the air flowing into the lamp, which forced the flame upward and lengthened it.

In the course of his remarks, he attempts to illustrate his idea by the effect that is produced when a piece of cardboard is held above the chimney of an ordinary house lamp, causing the lamp to smoke and the flame to reach upward in the chimney.

To my mind, the two lamps being entirely different cannot be compared. Bringing the cardboard over the top of the lamp chimney, of course, obstructs the flow of air and smothers the flame, causing it to smoke for lack of sufficient air for its combustion. The oxygen within the chimney being all consumed, the flame dies out.

The explanation given in the reply to this inquiry meets with my idea precisely. When gas is present within the lamp chimney, it is burned and a portion of the oxygen of the air is consumed. The natural result is to cause the flame to mount upward in its effort to reach the air required for the consumption of the carbonaceous matter of the flame.

Wilder, Tenn. OSCAR H. JONES.

What Caused the Wakesiah Mine Explosion

Violation of Mine Regulation Act—Facts show ignition started where the pumpman was working—Fireboss' lamp found in perfect condition.

I READ with interest the account given by Mine Manager W. H. Moore, *Coal Age*, Jan. 25, p. 184, regarding the Wakesiah mine explosion that occurred with fatal results at Naniamo, B. C., Nov. 24, 1922. Pardon me if I suggest that, in his account, he shows that he violated the terms of the Mine Regulation Act of British Columbia.

In the first place, he started to disturb a large body of firedamp accumulated at the face of a pitch and did not notify and withdraw from the place a pumpman who was then working on the return of that current. As a result, the pumpman was killed by the force of the explosion that occurred shortly after the body of gas was disturbed. The account states that the fireboss died of asphyxiation by reason of the afterdamp.

WHERE DID THE EXPLOSION START?

Mine Manager Moore does not state specifically at what point he considers the ignition of the firedamp took place. However, the facts given in his narrative point most strongly to the conclusion that the gas was ignited at or near the pumpman working on the return of the current. This man was killed instantly by the force of the explosion.

From his account Mr. Moore appears to think that the explosion occurred by reason of the failure of the fireboss' lamp. Notwithstanding the lamp is said to have been found in perfect condition following the explosion and to have been tested later when it withstood the test four times in succession and did not fail. The assumed failure of the lamp in the mine is, to say the least, mysterious.

In my opinion it is hard to believe that a double-gauze Wolf safety lamp would fail in this manner if properly assembled and rightly used by the fireboss.

WHAT HAPPENED AND EXACT MOVEMENTS OF FIREBOSS NOT CLEARLY EXPLAINED

It is hard to understand the exact movements of the fireboss from the description given by Mr. Moore. Seemingly the fireboss had extended the hose up the slant and deflected it in a manner to blow out the gas from its lodgment. His lamp was found 21 feet from the end of the hose and his body 84 ft. beyond the lamp. His shotfiring cable, detonators and electric fuses were found at the stopcock where he had turned on the air.

Now, assuming the ignition took place outby near where the pumpman was working, it is natural to suppose that the fireboss after turning on the air had proceeded up the slant, his lamp being found within 21 ft. of the end of the hose. In an endeavor to escape the afterdamp he had abandoned his lamp that was probably extinguished by the blast and rushed down the slant a distance of 84 ft. before being overcome by the gas.

If my supposition is correct the fireboss appears to have run considerable risk himself in advancing up the slant against the pressure of 90 lb. per sq.in. of gas-charged air blown by the nozzle of the hose from its lodgment in the roof. Again, had Mr. Moore's conclusion as to the failure of the lamp being the cause of the ignition of the gas been correct, it is more than likely that the fireboss would have been killed by the force of the explosion and the pumpman asphyxiated by the afterdamp.

In closing allow me to say in reference to the gauze showing signs of having been subjected to intense heat, it is a physical impossibility for a gauze to become red-hot without showing the same effect both outside and inside of the chimney.

In respect to the overheating of the gauze by reason of the lamp having been used for illumination seven hours, let me suggest that a safety lamp is safer when the wick flame is at its full height, provided it does not smoke. To my mind this claim is not evidence in favor of the lamp having failed in view of the condition in which it was found after the explosion.

Nanaimo, B. C. MINING ENGINEER.

Inquiries Of General Interest

Blowing vs. Exhaust Systems in Fan Ventilation

Advantage of Blowing System When Mine Generates No Gas—Exhaust System Must Be Employed in Ventilation of Gaseous Mines

ONLY recently, occurrences have led me to desire to look more carefully into the relative merits of the blowing and exhaust systems of ventillation. I think the subject was treated more or less fully in previous issues of *Coal Age*, but the matter has passed from my recollection and I desire now to obtain some information regarding the relative advantages and disadvantages of these two systems and the conditions under which the one or the other should be employed. As I recall, the choice betwen the two systems, in the ventilation of a mine, is not an arbitrary one, but depends solely on the conditions to be met in the development of the mine. I hope it is not asking too much to have the advantages and disadvantages of the two systems explained again in the columns of *Coal Age*. It will doubtless interest many like ourselves.

W. B. BROWN,
Searles, Ala. Supt. Aetna Mine.

As this correspondent has stated, the choice between the blowing or exhaust system of ventilation in the operation of a mine is not an arbitrary one. Each system has its peculiar adaptation to the conditions that will prevail in the operation of the mine, particularly with reference to the haulage of the coal. In the working of a seam generating gas, it is of the utmost importance that the main haulage road should be made the intake airway. On the other hand, if the mine generates no gas it is equally important that haulage should be performed on the main return airway.

In the former case, hauling the coal on the main intake airway avoids the danger of gas being ignited by the lamps of the drivers or motormen, who cannot conveniently use safety lamps in their work. Of course, there is no better light for a driver or motorman to use than the electric cap lamp and, since its advent in coal mining, there is not the same urgency for hauling coal on the intake as before. However, the danger is not wholly eliminated, as the breaking of an incandescent bulb is liable to cause the ignition of the gas.

Again, in the working of a non-gaseous mine, the advantage of hauling coal on the return airway is that the loaded cars move with the current and there is less obstruction to the flow of the air than when the full loaded cars must move against the current. Again, all the dust of the haulage road is carried out of the mine when hauling on the return current. Moreover, the hoisting shaft is then the upcast and the formation of ice in the winter is largely or wholly prevented by the warm air returning from the mine.

It will be understood, that, for practical reasons, the blowing fan can only be used when the main haulage road is made the intake airway. In that case, in order to avoid the use of doors on the shaft bottom, it is necessary to install an exhaust fan at the air shaft, leaving the hoisting shaft and the main haulage road unobstructed.

In the exhaust system, the mine is ventilated under a pressure less than that of the atmosphere. As compared with the blowing system of ventilation, the exhaust system makes possible the igniting of the gases issuing from abandoned workings. Because of the reduced mine pressure these gases are forced out into the live workings by reason of the greater atmospheric pressure acting through openings and crevices reaching to the surface.

Offsetting this condition, however, it is claimed that, in the blowing system, any cessation of the fan is followed immediately by the expansion of the pent up gases in abandoned workings, the outflow of these gases into the live workings being at the most critical time.

As far as the ventilator is concerned, when exhausting the air from the mine, the fan is filled with the warm air of the mine having a less density than the cold outside air that fills the fan when operated as a blower. The lighter air filling the exhaust fan has a tendency to decrease the efficiency of the ventilator. In the use of the exhaust system to ventilate a gassy mine, the density of the mine air is still further reduced by the presence of a greater or less percentage of methane.

The points mentioned above are the principal advantages and disadvantages of the exhaust and blowing systems of ventilation. Those of chief importance, however, are the ones relating to making the main haulage road the intake for the mine when the latter is generating gas. Such an arrangement demands the use of the exhaust fan to avoid the obstruction of the main haulage road by doors that would be required in the use of the blowing system under those conditions.

Examination Questions Answered

Miscellaneous Mine Examination Questions

(Answered by Request)

QUESTION—*Explain the principle of the ventilating fan. What conditions in the mine would govern you in determining the diameter and width of the fan?*

ANSWER—The principle of the centrifugal fan, which is the common type of ventilating fan in mining practice depends on the centrifugal force developed by the revolution of the weight of air contained within the fan blades. This centrifugal force is exerted radially from the center toward the circumference of the fan. As a result air is drawn in at the center of the fan and thrown out all around the circumference where it is conducted by a spiral casing to the fan drift or to the chimney as the case may be.

Briefly, the diameter of the fan is a function of the pressure the fan will produce, the latter being determined directly from the peripheral velocity of the blade tips. These two factors, in fan design, must therefore be proportioned to the unit of ventilating pressure or water gage desired. Always, the pressure developed by a fan will depend on the resisting power of the mine airways, which is determined by the quantity of air in circulation and the rubbing surface of the airways.

Again, the width of the fan is practically a function of the quantity of air to be circulated or the quantity of air the fan will handle under the same conditions in the mine.

QUESTION—*A volume of air of* 140,000 *cu.ft. per min. is delivered at the foot of the downcast shaft and there divided into three splits as follows: Split A,* 6 x 7 *ft.,* 5,000 *ft. long; split B,* 6 x 6 *ft.,* 4,500 *ft. long; split C,* 6 x 5 *ft.,* 4,000 *ft. long. What quantity will pass through each airway?*

ANSWER—The first step in the solution is to find the areas, perimeters and lengths of each of the several splits, which are as follows:

A, 6x7 ft., 5,000 ft. $a = 6x7 = 42$ sq.ft. $o = 2(6+7) = 26$ ft. $l = 5{,}000$ ft.
B, 6x6 ft., 4,500 ft. $a = 6x6 = 36$ sq.ft.; $o = 2(6+6) = 24$ ft. $l = 4{,}500$ ft.
C, 6x5 ft., 4,000 ft. $a = 6x5 = 30$ sq.ft.; $o = 2(6+5) = 22$ ft. $l = 4{,}000$ ft.

The relative values of the areas, perimeters and lengths of these airways are as follows:

Split A..... $a = 7$; $o = 13$; $l = 10$
Split B..... $a = 6$; $o = 12$; $l = 9$
Split C..... $a = 5$; $o = 11$; $l = 8$

Substituting these relative values in the formula for the relative potential factor gives for the relative split potentials:

Split A..... $a\sqrt{\frac{a}{lo}} = 7\sqrt{\frac{7}{10 \times 13}} = 1.624$

Split B..... $= 6\sqrt{\frac{6}{9 \times 12}} = 1.414$

Split C..... $= 5\sqrt{\frac{5}{8 \times 11}} = 1.192$

4.230

Since the quantity passing in each split is proportional to the split potential, we have

Split A..... 4.230 : 1.624 :: 140,000 : x = 53,750 cu.ft.
Split B..... 4.230 : 1.414 :: 140,000 : x = 46,800 cu.ft.
Split C..... 4.230 : 1.192 :: 140,000 : x = 39,450 cu.ft.

Total ..... 140,000 cu.ft.

QUESTION—*If* 65,000 *cu.ft. of air per minute passes through an airway* 7 x 7 *ft. in section, with a water gage of* 1.5 *in., what quantity of air will pass through another airway* 8 x 8 *ft. in section, the pressure remaining the same?*

ANSWER—These airways being square in section and having the same length and unit pressure, the square of the quantity of air in circulation will vary as the fifth power of a single side. In other words, the square of the quantity ratio is equal to the fifth power of the ratio of the sides of the two airways. Thus, calling the required quantity of air passing in the second airway x we have

$$x = 65{,}000\sqrt{\left(\frac{8}{7}\right)^5} = 90{,}760 \text{ cu.ft. per min.}$$

QUESTION—*If in an airway* 72 *sq.ft. in sectional area the velocity is* 550 *ft. per min. what will the velocity be if the area is decreased to* 60 *sq.ft.? What is the horsepower in each case, assuming a water gage of* 1.9 *in.?*

ANSWER—The question does not state how the reduction in sectional area has taken place. It is natural to assume that this occurred by reason of a square that reduced the height of the airway while the width remained unchanged. Then, assuming an original section 8 x 9 ft. is reduced to 8 x 7½ ft., the perimeter ratio due to the squeeze is 34:31; while the area ratio is 72:60. Assuming a constant water gage or pressure and a constant length of airway, the square of the velocity of the air varies directly as the sectional area and inversely as the perimeter. In other words, the square of the velocity ratio is equal to the product of the area ratio and the perimeter ratio and we have for the required velocity after the squeeze

$$v_2 = 550\sqrt{\frac{60}{72} \times \frac{34}{31}} = 525.8 \text{ ft. per min.}$$

QUESTION—*What is the equivalent orifice of a mine that passes* 80,000 *cu.ft. of air per minute, under a water gage of* 1 *in.?*

ANSWER—The equivalent orifice of a mine is based on the ratio of the quantity of air in circulation to the square root of the water gage, as expressed by the formula,

$$\text{Equiv. Orifice} = \frac{0.0004\,Q}{\sqrt{w.g.}}$$

Substituting the given values in this formula gives for the equivalent of this mine $(0.0004 \times 80{,}000) \div \sqrt{1} = 32$ sq.ft.

QUESTION—*When a rope carrying a load is run over a sheave wheel to what two stresses is it subject?*

ANSWER—When a rope passes over a sheave it is subject not only to the actual load it carries, but that portion bent around the sheave is under an additional stress due to bending. The strength of the rope must, therefore, be estimated with regard to both the actual load and the bending stress, the sum of the two being the working load.

QUESTION—*To what cause or causes are sudden outbursts of gas generally due?*

ANSWER—Outbursts of gas in mines frequently occur as the direct results of the extraction of the coal. As this proceeds, the pressure of the gas overcomes the strength of the coal or the strata in which it is contained, whereupon it is liberated in large volume.

World's 1922 Coal Output Less Than Any Year Except 1921 Since 1915

World's total production of all coal in the calendar year 1922, according to information now available, the Geological Survey reports, was 1,200,000,000 metric tons. This was a little larger than the output in 1921, but it was less than in any preceding year since 1915 and less than in the pre-war years 1912 and 1913. The United States' share was 417,000,000 metric tons, or 34.8 per cent of the total, as against 40.5 per cent and 40.5 per cent, respectively, in 1921 and 1920.

The following table presents the information received up to March 8, 1923. The tonnages for countries not yet heard from ordinarily amount to about 6 to 10 per cent. Receipt of data for these countries may raise or lower the final figure by some millions of tons. The table presents figures for 1920 and 1921, embodying precise data and revised estimates for countries from which only preliminary estimates had heretofore been available. Lignite and brown coal are included; where possible they are given separately.

COAL PRODUCED IN THE PRINCIPAL COUNTRIES OF THE WORLD IN THE CALENDAR YEARS 1920, 1921 AND 1922*

(In metric tons of 2,204,622 lb.)

* Prepared by W. I. Whiteside, U. S. Geological Survey.
(a) Estimate included in total. (b) Estimated on 11 months' production. (c) Includes the Saar basin. (d) Includes entire output of Upper Silesia from January-May, inclusive. For months June-December only the output of the portion of Upper Silesia awarded to Germany is included. (e) Includes output of the portion of Upper Silesia awarded to Poland for months June-December, inclusive.

Record Output of Briquets Made in 1922

A new record of production of fuel briquets was established in 1922, when, according to reports to the U. S. Geological Survey, the total output was 619,425 net tons, against 398,949 tons in 1921. In comparison with 1920, the year in which the previous maximum was attained, the increase was slightly over 9 per cent. Production in all districts in 1922 was larger than in the year before, the principal increase occurring in the Central States. The chief factor in the improvement in that territory was the increased demand for briquets to make up the deficit in domestic anthracite in the region supplied from the Upper Lake Docks.

FUEL BRIQUETS PRODUCED IN THE UNITED STATES IN 1917-1922

Year	Net Tons	Value	Year	Net Tons	Value
1917	406,856	$2,233,888	1920	567,192	$4,623,831
1918	477,235	3,212,793	1921	398,949	3,632,301
1919	295,734	2,301,054	1922	619,425	5,444,926

With the exception of the General Briquetting Co., at New York City, which plant was dismantled late in 1921, all plants that were active in 1921 were operated in 1922. Each plant used the same raw fuel constituent and the same type of binder as in the year preceding.

RAW FUELS USED IN MAKING BRIQUETS IN THE UNITED STATES, 1919-1922

(In Net Tons)

Fuel	1919	1920	1921	1922
Anthracite culm and fine sizes and semi-anthracite	118,595	356,877	190,964	254,563
Semi-bituminous and bituminous slack and coke	a97,387	a125,506	121,925	235,542
Lignite, sub-bituminous coal, and oil-gas residue	80,383	89,656	b85,352	b123,339
	295,365	572,039	393,241	613,444

a Includes no coke. b Includes no brown lignite.

Of the 14 plants that operated, 6 used anthracite culm or fines, 2 semi-anthracite, 1 a mixture of anthracite fines and bituminous slack, 1 semi-bituminous slack, 1 a mixture of bituminous slack and sub-bituminous coal, 2 carbon residue from the manufacture of oil gas, and 1 bituminous coal, first subjected to low-temperature carbonization. The total quantity of raw fuel used was 609,186 net tons, of which 42 per cent was anthracite or semi-anthracite, 39 per cent semi-bituminous slack, bituminous slack and coke, and 19 per cent sub-bituminous coal and oil gas residue.

Utilities Coal Consumption in January 24 per Cent Higher Than Year Ago

Electric public-utility plants consumed 3,552,053 net tons of coal during January according to a recent report of the Geological Survey. This compares with 3,596,623 tons consumed during December, according to corrected returns.

The average daily production of electricity by public-utility power plants in January was at the unprecedented rate of 151,900,000 kw.-hr., an increase of nearly 24 per cent over January, 1922, and an increase of nearly 2 per cent over the previous record rate established in December.

New England Coal Receipts in 1922 Less Than in 1921 and 1919

The full effect of the miners' strike during the past summer on receipts of coal in New England during 1922 is shown in preliminary reports of the Massachusetts Commission on the Necessaries of Life, according to the Geological Survey. New England received less coal in 1922 than in 1921 and 1919, which were, respectively, years of industrial depression and a great coal strike. The 1922 receipts were much smaller than in any other recent years. The total quantity of anthracite received in 1922 was 6,462,000 net tons, and bituminous coal, 18,815,000 tons, which amounts were but 56 and 85 per cent, respectively, of the average receipts during the six years preceding.

Coal received during the year included about two million tons of foreign bituminous coal, nearly all of which entered New England ports after the middle of the year.

NEW ENGLAND COAL RECEIPTS*a*

(Net Tons)

Period	Anthracite Tide	Anthracite Rail	Anthracite Total	Bituminous Tide	Bituminous Rail	Bituminous Total	Aggregate
January to July, 1922	982,000	2,277,000	3,259,000	6,672,000	2,863,000	9,535,000	12,794,000

"Fireproof Anthracite" Causes Storm of Protest in East; Six Shippers Found; I. C. C. Does Nothing

Recent shipments of doubtful black material from anthracite waste piles in Pennsylvania by several unknown concerns caused a storm of protest to rage through parts of the East last week. It gave sensational newspapers an opportunity to deal a black eye to legitimate anthracite reclamation while hitting at the "wildcatters" and drew a statement from the General Policies Committee of the Anthracite Producers. Federal Fuel Distributor F. R. Wadleigh, after an investigation by George T. Haldeman, said six companies had been located. On Feb. 12 and Feb. 26 Mr. Wadleigh asked the Interstate Commerce Commission to refuse cars to such shippers, but the commission, in a letter March 12 from Commissioner Potter said the matter was one for the Pennsylvania courts and not for it to settle.

Commissioner Potter wrote Mr. Wadleigh as follows under date of March 12:

> Your letter of the 26th ultimo was submitted to the commission for consideration at our regular conference held on the 5th instant, upon which date the commission directed that the subject have the consideration of our Bureau of Inquiry preliminary to further action by the commission. Consideration by the Bureau of Inquiry having been had, the subject was again considered by the commission at the conference today. The decision of the commission was that we should not embark upon the investigation and hearing suggested by you in your letter of the 26th ultimo. It is the thought that the subject is primarily one that should not be dealt with by the regulation or denying of interstate transportation, but rather through the enforcement of criminal or civil laws of the state having jurisdiction to punish criminal offenses or redress contract violations, etc.
>
> This is the unanimous view of the members of Division 5, concurred in and approved by the commission.

On March 13 Mr. Wadleigh sent the following letter to Commissioner Potter:

> I have received your letter of March 12 in response to my letters of Feb. 12 and 26 in regard to shipments of unmerchantable coal . . . and regret that the commission finds itself unable to take any action that will assist in preventing the shipment of unmerchantable coal in interstate traffic. The case submitted to you is characteristic of a number of others which have been reported to this office and it was my hope that the power and authority of the Interstate Commerce Commission would be found available in such cases for the protection of the public from transactions of the character charged. . . .
>
> I return for your files my letter to you under date of Feb. 12 which was returned with your letter of Feb. 24 through an apparent inadvertence.

That both the Federal Government and the State of Pennsylvania possess ample police powers to punish anyone convicted of shipping or selling coal mixed with waste or other non-combustible material is the belief of Senator Pepper stated March 14 in a letter he addressed to Governor Pinchot of Pennsylvania, in which he incorporated a telegram he sent to the *New York American*, in response to one he received from it inviting him to join other Senators in visiting the Pennsylvania anthracite regions to determine how much alleged adulterated anthracite is being sold consumers.

Senator Pepper expressed the opinion that the "real problem is one of prevention and punishment. Since adequate inspection under existing law is impracticable, the most effective prevention would be an order of the Interstate Commerce Commission refusing railroad facilities to adulterated fuel in case the commission regards such order as justifiable."

A copy of Senator Pepper's letter to Governor Pinchot also was transmitted to James S. Benn of the Pennsylvania Public Service Commission.

Mr. Pepper also pointed out that the local District Attorney possessed ample jurisdiction to prosecute any company or individual handling such coal.

Mayor Hylan, of New York City, informed the members of the Board of Estimate at its meeting on March 16 that he had received a telegram from the *New York American* requesting him to invite them to accompany a committee of prominent persons on a tour of the coal fields for the purpose of obtaining first-hand information as to the preparation of coal in culm banks for the market. The matter was referred to the committee of the whole for action at its meeting scheduled to be held on March 21.

The telegram follows: "Will you and members of the Board of Estimate plus a similar committee of important persons, including a few state legislators, go as guests of the *New York American* to the coal fields to see what is being done by mine operators in the way of sending culm bank coal to New York? Please observe big exposé story in Monday's *American*. Personnel of committee will be entirely in your hands."

In his investigation of "dirt shippers" for the Fuel Distributor, Mr. Haldeman said six companies are "very active in the disposal of unmerchantable anthracite coal." Mr. Haldeman found every indication that these companies are deliberately putting on the market material from culm banks which contains a high percentage of non-combustible material. A former prize fighter, a former saloonkeeper, an ex-convict and others of questionable repute were found to be engaged in the production and sale of low-grade coal. In one instance the report finds that "no attempt is made to separate coal and impurities. The material contained in the run-of-bank is crushed, sized, run into bins and placed on the market."

In another case operations were in progress on a dump consisting "of masses of ashes, rock and slate interspersed with coal irregularly distributed." It is said that this particular bank had been worked over by the Hudson Coal Co. previous to this operation.

"The use of Wilmot jigs on the nut and pea size," reports Mr. Haldeman, "indicates that the company is fully aware of the quality of material prepared for the market." In another case the breaker was being operated by the "dry method." No water for washing the coal is available at the point where the little plant was erected. Much of this coal is marketed "as is" and in some cases sales contain the stipulation "nothing guaranteed." At one of the properties Mr. Haldeman found the breaker in a tumble-down and dangerous condition, with no evidence of jigs or other means of washing coal.

Vivid Copy for Sensational Journals

Such operations as those of the six companies investigated by Mr. Haldeman have furnished vivid copy for sensational newspapers. The fact that these publications failed to distinguish between legitimate reclamation and "wildcatting" drew a reply from the anthracite operators.

Legitimate reclamation of anthracite, which was once cast aside for want of a market, has been producing good coal from great waste piles for more than thirty years. It began to develop in 1890 following the invention by Eckley B. Coxe of a grate and stoker that would handle small sizes.

Coxe had vision. He sensed the problems that would face the future of the industry in which his interests were involved. It was largely through his efforts that the Pennsylvania Legislature enacted the law providing for the Anthracite Coal Waste Commission to study the causes of waste and recommend preventive measures. It began its work in 1890 and completed its report in 1893. One of the benefits derived from this investigation was the invention of the Coxe grate and stoker. Another was the development of markets for chestnut and pea sizes. When these had been accomplished the recovery of the formerly wasted fuel thrown on the so-called culm banks was made possible.

The first recovery of anthracite from the culm banks was coincident with the appointment of the Commission, the first shipments from washeries being reported in 1890, when 41,600 tons of washery coal were sent to market. By 1895 the shipments of washery coal had reached a little more than 1,000,000 tons and five years later exceeded 2,000,000 tons. In 1907 they amounted to a little more than 4,300,000 tons, or 6.4 per cent of the total anthracite shipments, after which they gradually declined until 1914, when they amounted to 1,736,750 tons. The world war stimulated demand for all kinds of coal and the washeries increased their contributions to the needed supply as follows in gross

tons: 1915, 2,492,639; 1916, 3,133,609; 1917, 5,412,709; 1918, 6,630,923.

In the slump that followed the armistice the production of washery coal dropped to 3,165,393 tons, but increased in the boom of 1920 to a little more than 5,000,000 tons and dropped again in the depression of 1921 to the lowest point since 1900—or to 1,537,147 tons.

The story of the recovery of this coal is one of the most striking examples of the conservation of natural resources and of the elimination of waste in a great industry that the history of our country records. During the period from 1890 to 1921 more than 75,000,000 tons have been recovered and it has been estimated that about 30,000,000 tons are still to be saved and used. Washery output of anthracite always is separately reported by the Geological Survey.

It is well known that anthracite does not deteriorate in storage and that the quality of the coal in the culm banks and in the river and creek bottoms is of as good fuel quality as when it was put there. It is also well known that as much care is taken to separate this coal from the impurities deposited with it as is done with the fresh-mined product. The washeries were constructed for that purpose. One of the earliest of the dredges devised for recovering "river" coal was built and operated by the Harrisburg Light & Power Co. for use in its power plant—a singular performance for a corporation if the quality of the fuel were such as to make it unfit for use.

It is also well known to the trade, though it may not be so well known to the anthracite-consuming public, that by far the larger proportion of the coal reclaimed by washeries and dredges is of sizes below chestnut. In 1917, the first of the war years' large production of washery and dredge coal, the quantity of egg, stove and chestnut included in the washery output was 555,000 tons (457,000 tons of this being chestnut) out of a total of 5,365,517 tons. The total production of domestic sizes in the fresh-mined product of that year was 46,447,104 tons, so that the percentage of mixture of washery coal in the total was a fraction over 1.

In 1918 the total production of fresh-mined domestic anthracite was 45,124,390 tons, while the domestic sizes in the washery production were 670,000 tons, or about 1½ per cent of the fresh-mined domestic tonnage. In 1921, a more normal year, the fresh-mined domestic anthracite was 45,650,613 tons, while the washery product of chestnut and larger was 255,184 tons, or a little over 0.5 per cent.

Washery owners have been charged with selling this product to the consumers at $15 a ton. The best answer to this is that according to the U. S. Geological Survey the average realization to the operators for the washery tonnage (including the 255,000 tons of domestic sizes) was $3.64 per ton, while the average realization on the fresh-mined coal was $6.266 per ton.

If it had not been for the reclamation of this previously wasted coal, which it is admitted is recovered at a much less expense than the fresh-mined coal, it is probable the public would have paid more per ton for its domestic sizes than it has paid, and when the culm banks are exhausted—as they will be in about a decade—the effect will be shown in increased prices.

Southwestern Field Is Closing Down Fast

Mines throughout the southwest are being closed down for lack of business. The Cherokee Coal Co. has closed one of its Kansas mines and proposes before long to close others. While the Central Coal & Coke Co. has not yet shut down any of its Kansas mines, it expects to before long, and has already closed six of its Arkansas shafts, decreasing its production in that field approximately 3,500 tons a day. The Sheridan Coal Co. has closed three of its mines in Kansas. The Home Riverside Coal Co., while continuing to operate its machine mine, has closed its 300-ton pick mine at Leavenworth, Kan. Many small concerns in Kansas, Arkansas, Missouri and Oklahoma have shut up shop, and larger operators are faced with the necessity of decreasing production this month in fields where mines now are operating only from one-fourth to one-third time.

It has been the mildest winter in the memory of coal men, with not even sufficient demand for domestic coal to provide screenings for the steam buyers.

New Coal Commission Questionnaire Seeks Data on Wage Rates and Changes

The U. S. Coal Commission is sending out a new questionnaire designated Form W-1, the main purpose of which as stated in the letter accompanying it, is "to obtain the information on wage rates and changes in wage rates indicated in the schedule."

In fields 100 per cent union only two or three companies are to be requested to furnish this information; but in non-union fields and in fields in which both union and non-union operations are carried on the questionnaire is to be sent to all operators whose production in 1920 exceeded 100,000 tons.

The questionnaire consists of three parts. The first part covers the question of changes in wage rates from Jan. 1, 1912, to Jan. 1, 1923. Columns are provided in which the operator is instructed to "give the day, month and year of each change in rates affecting the whole of one occupation or more." Provision is made for recording twelve changes in rates between April 1, 1912, and Jan. 1, 1923.

The second part of the questionnaire calls for rates of pick miners, machine cutters and hand-drill loaders as of Jan. 1, 1923, showing separately the rates for rooms, entries, breakthroughs listed below. The third part of the questionnaire calls for special information of various kinds.

West Kentucky to Renew Contract; Jackson Says National Strikes Are Gone Forever

The West Kentucky Coal Operators Association met in Louisville on March 12 with representatives of District 23, United Mine Workers, and continued discussions relative to renewal of the wage scale which has been in effect for two years but which expires on March 31. This agreement contains a no-strike clause which was maintained during the general strikes last spring. It is understood that the agreement will be renewed without any difficulties.

Day inside workers are paid from $6.59 to $6.95; loading rates are 74 to 76c. a ton; pick mining on mine-run, $1.05 a ton and for outside work, $6.06 a day. The day is eight hours. Lonnie Jackson, president of District 23, headed the miners' delegates. Jackson is Mayor of Central City, Ky. He gave out an interview saying that nation-wide coal strikes probably would be a thing of the past, and held that mine workers now realize the cost of such ventures, not only to themselves but to industry. He labeled as "mere bunk" any talk of strikes in the near future. In his district there are more than 12,000 men, who are contented, and indications are for quiet industry, which Jackson says, is the need of the hour. Mines are working two and one half to three days a week. Harmony has marked all discussions between operators and miners.

National Coal Association to Hold Annual Convention in Atlantic City

The National Coal Association will hold its sixth annual convention in Atlantic City from June 19 to 22, inclusive. The meeting of the Board of Directors and the various committees of the association will be held on June 19, the convention proper beginning on June 20. The convention program has not yet been completed, but as soon as final arrangements are perfected and speakers have been selected announcement will be made. The headquarters of the association during the convention will be the Hotel Traymore.

The special committee which has charge of arranging the program and other details of the convention is as follows: W. H. Cunningham, president, Cunningham, Miller & Enslow, Huntington, W. Va., Chairman; C. E. Bockus, president, Clinchfield Coal Corporation, New York City; J. C. Brydon, president, Quemahoning Creek Coal Co., Baltimore, Md.; Ira Clemens, president, Clemens Coal Co., Pittsburg, Kan.; Michael Gallagher, general manager, M. A. Hanna & Co., Cleveland, Ohio; S. L. Yerkes, vice-president, Girder Coal Sales Agency, Birmingham, Ala.

Coal Commission's Work on Production Cost and Waste In Mining Is Ahead of Schedule

Marked Discrepancies in Wholesalers' Returns in Different Sections—Dr. Smith Resents Criticism of Culm-Bank Workings — Commissioner Marshall Foresees Trouble in Somerset County and Advises Self-Probing by Other Industries

By Paul Wooton
Washington Correspondent of *Coal Age*

Additional funds and new teeth in its organic act have speeded up the work at the offices of the President's Coal Commission. The force has grown from 174 to 216 in two weeks. Field inspectors have been dispatched to each of the mining districts to gather information on causes of strikes. This work, which is under the immediate direction of Dr. Joseph H. Willits, in charge of labor relations for the commission, will be expedited particularly in the anthracite region.

Despite the uncertainty which resulted from the delay in obtaining legislation, the work on production costs and on waste in mining actually is ahead of the rather ambitious schedule which was prepared when the commission mapped out its work.

Returns to the commission on the gross margins of wholesalers show baffling discrepancies between different cities and different parts of the country. In some instances the gross margins in 1922 were no greater than those of 1921. In a number of other cases wholesalers doubled their margins in 1922.

In discussing, on March 17, the progress of the week Commissioner Smith took exception to some of the newspaper attacks on the practice of working over culm banks. This practice should not be discouraged, he said. It is conservation and is in the public interest. The washeries employ 1 per cent of the men engaged in anthracite production, but produce 6 per cent of the total shipments of that type of coal. An overwhelming proportion of the banks that are washed produce a higher grade product than the freshly-mined coal. The objection to this practice, Dr. Smith pointed out, comes from a few unscrupulous operators and dealers, who are shipping an insignificant percentage of the total tonnage. Some of these dealers, he stated, are avoiding trouble with the postal authorities by refraining from the use of the mails and are conducting their negotiations by telegraph.

After having conferred with operators and with representatives of the United Mine Workers in the South, Commissioner Marshall is impressed with the "you are another" situation in the coal industry. "There is not a great deal of dispute as to the real civic rights of the American citizen," he said, "but there is sharp dispute as to whether these rights have been violated and by whom."

Hope to Determine Rights of Citizens

Governor Marshall is taking up the charges and countercharges that have been made with the idea of determining whether the law or the rights of citizens have been violated. "The past is the eternal past, however," he observed, "except in so far as the legal authorities deem it their duty to arrest and punish men who have violated the law. The hope of the commission is to settle definitely, to the satisfaction of all concerned, what are the real rights of an American citizen. The commission will bend its best efforts to the end of getting an acknowledgment of those rights and a public pledge of obedience to the law and of preservation of those rights in the future."

"A conflict is brewing in Somerset County," continued Governor Marshall. "We are having men investigate the matter for us, so that if trouble occurs we can find out who is responsible. If trouble should occur, we hope there will be found, on each side, a tendency to frown down any violation of law and a disposition to assist in bringing to punishment any individual who attempts to break the law.

"There is a tendency for each side to clothe itself in white garments and to say in the language of Shakespeare 'thou canst not say I did it.' An opportunity may be presented in Somerset County for the parties to the controversy to disclose their real Americanism by procuring and defending their rights in lawfully constituted courts rather than with the use of clubs, pistols or dynamite, and by insisting on the punishment of any man who resorts to force in obtaining his rights.

"If we are to justify our democracy, now is a good time to put the soft pedal on hate and allow to roll out the chorus of brotherhood, conciliation and compromise. Other business under public suspicion should take warning from the necessity of the coal investigation to probe themselves and determine whether there has been a square deal in all the departments of the business. These investigations are regrettable. It is unfortunate that they have to be. We should all glory in the progress of America. No right-thinking man is jealous of the success of his neighbor. The world held the ragged Continental in veneration long after it had forgotten the rich and the poor profiteer. It is a good thing to make money. It is a good thing to receive high wages, but the finest thing is to contribute to the reality of democracy.

"There is something wrong in the coal industry. Spring housecleaning is in order, but it is not for me at this stage to express an opinion as to whose is the responsibility."

In commenting on his Southern trip, Governor Marshall stated that he was much impressed with the model villages and fine hospitals of the Tennessee Coal, Iron & Railroad Co., but they caused him to wonder "how far in the long run is the common good of a people advanced by benefactions handed down from above."

Field Investigators Now at Work

Field investigators engaged to examine into the question of causes of strikes have recently gone into the field for the coal commission. The following are those recently engaged by Professor Willits, who has charge of this phase of the work:

Prof. Willard E. Hotchkiss, formerly secretary of the Shipbuilding Labor Adjustment Board and dean of the School of Commerce of Northwestern University, and Secretary of the President's Industrial Congress.

John S. Keir, the head of the Department of Industrial Economics at Carnegie Institute of Pittsburgh.

O. Le Preble, who specialized on personnel relations in several industries and as examiner for the Shipbuilding Labor Adjustment Board handled industrial relations in the shipyards of New England for the Navy Department.

Royal S. Melendy, whose work in labor management included connection with the Stevenson Corporation in New York, and the Firestone Tube & Rubber Co., of Akron.

Otto T. Mallery, who was a member of the State Industrial Board of Pennsylvania.

Dr. Boris Emmett, formerly with the Department of Labor and for some years the labor manager for H. Sonneborn & Co. at Baltimore.

S. B. Mathewson, who is now the director of personnel for Antioch College and was formerly with the Scott Company, industrial consultants.

Charles Frazier, until recently an investigator employed by the International Association of Machinists.

Russell G. Wagenet, labor manager of the clothing industry at Rochester.

Henry S. Gilbertson, formerly associated with Dr. Hotchkiss and now with a firm of industrial engineers engaged in organization work for the State of Kentucky.

At Hoover's Request Wadleigh to Study Transportation, Community Storage and Co-operative Marketing

Studies of community storage of coal, of certain phases of coal transportation and of co-operative marketing of coal are to be conducted by Federal Fuel Distributor F. R. Wadleigh. These studies are being made under the powers vested in the Fuel Distributor and at the request of Commerce Secretary Hoover. The work will be co-ordinated with that being done by the President's Coal Commission.

Mr. Wadleigh calls particular attention to the fact that the study of community storage will not enter upon the problems of municipal storage. The work is being done with no preconceived ideas that all phases of the problem of central storage in cities can be brought out. The study will include the matter of motor-truck distribution.

The study of transportation will deal with coal-car distribution other than the allotment of cars to mines. Particular attention will be given to the movement of coal cars, which will include an analysis of delays which may result from inadequate motive power, inadequacy of terminals, or other parts of the railroads' plant. This portion of the study will be under the immediate direction of E. A. Blake, until recently general superintendent of the Eastern division of the Norfolk & Western R.R.

The success which has attended co-operative marketing of farm products and other commodities has led many students of the coal situation, including Secretary Hoover, to believe that collective selling of coal would mark a step forward. The application of the co-operative marketing principle to coal never has been the subject of any profound study and it is believed that an analysis can be made of the possibilities of such a plan, which will give a much clearer idea of where it may lead.

The object of these studies is to develop facts and correlate the best opinion as to their solution, but no recommendations as to legislation are to be made.

Why Were Troops Not Sent to Herrin? Illinois Legislature May Find Out

While the second trial for wholesale murder at Herrin, Ill., last June droned along at Marion, Ill., without interesting developments last week, something relating to the Herrin mine massacre was going on in the State Legislature at Springfield. A Democratic member of the Illinois House declared Carlos Black, state adjutant general, was at fault for not sending state troops to prevent the Herrin riot and got the House to pass a resolution calling for a legislative investigation. The resolution has not been adopted yet by the Senate.

The attack in the House is not so much a move against the adjutant general as it is in an effort to embarrass Governor Len Small, who appointed him. However the verbal assault was centered upon Black for dereliction of duty and for trying to lay the blame upon Colonel Sam Hunter, who represented the adjutant general at Herrin before and during the massacre which followed the surrender of 48 non-union strip miners to a mob which shot and cut 21 of them to death. Colonel Hunter's reports show that three times he advised that troops be sent to Herrin, but the adjutant general did not comply because the local authorities did not join in the appeal.

The Chicago Tribune recently advocated editorially that the christian churches of the United States expend a good deal of their missionary effort in Williamson County instead of among alien peoples. "There is need in Williamson County, if anywhere," says this newspaper, "for an evangel of mercy and for a vigorous teaching of the fundamentals of christianity or even of ordinary uninspired humanity. We think there will be a reproach upon all foreign missionary effort while in our own vineyard the beast goes untamed."

International Mine-Rescue Meet to Be Held In Salt Lake City August 27-29

The Seventh International First-Aid and Mine-Rescue Meet will be held in Salt Lake City Aug. 27, 28 and 29, under the auspices of the U. S. Bureau of Mines, in co-operation with the National Safety Council, the American Red Cross, miners' organizations, operators' associations and other agencies.

Although sixty-three teams of miners from almost every mining community in the United States and a championship first-aid team from British Columbia, Canada, competed in the last international contests, which were held in St. Louis in 1921, and representatives of the governments and mining industries of Great Britain, Mexico, France and Belgium also attended the meeting, it is expected that, with promises of continued operation of coal mines during the summer months, the number of teams entered in this year's contests will exceed all previous entries.

With the advent of the trained rescue miner, wearing the oxygen-breathing apparatus, has come the trained first-aid man who takes the victim of a mine disaster and gives him the emergency aid that oftentimes means the difference between life and death. Today there are more than 100,000 men in this country trained by the Bureau of Mines in modern first-aid or mine-rescue work or both, all of them volunteers, ready to help their own or those in some other place, no matter where.

In the contests to be held in Salt Lake City competition between the various teams will be held under conditions approximately as closely as possible those found at a mine during an accident.

Retailers Tender Aid to Coal Commission In Collation of Data

The Board of Directors of the National Retail Coal Merchants' Association at a meeting held March 19 at the Hotel Pennsylvania, New York City, which was open to all members of the New York State Coal Merchants' Association, adopted a resolution to co-operate fully with the U. S. Coal Commission in obtaining the information desired by the commission in the questionnaire sent to the retail trade. To aid in this work a committee was appointed to assist in the work of preparing the answers required. This committee consists of Roderick Stephens, New York (chairman); Marshall Keig, Chicago; E. R. Sweeney, Kansas City; Maurice Klaus, Boston; Samuel B. Crowell, Philadelphia, and Homer D. Jones, president of the National Retail Coal Merchants' Association, Chicago, ex officio.

There were about 200 persons present at the dinner given in the evening at which brief addresses were made by President Jones and Lawrence F. Ferguson, president of the Chicago Retail Merchants' Association. There was a vaudeville program.

The annual convention of the association will be held in Scranton, June 25, 26 and 27. Headquarters will be established in the Hotel Casey.

THE U. S. SUPREME COURT is to receive the cost-reporting case of the Claire Furnace Co. versus the Federal Trade Commission. As this is a test case to determine the scope of the powers of the Federal Trade Commission in demanding returns on costs, no objection was made to the appeal, which will result in a final decision of this litigation.

THE PUBLIC UTILITIES COMMISSION of the District of Columbia discontinued the regulation of anthracite distribution on March 15.

American Coal Export Trade Shows Effects of French Occupation of Ruhr

Occupation of the Ruhr coal field by the French, with consequent decrease in its coal production, entailing as it does shutting off supplies to Italy, France, Germany and other European countries, according to F. R. Wadleigh in *Commerce Reports*, has had a marked effect on our coal export trade and has already resulted in the placing of orders for a considerable tonnage from this country, together with many inquiries.

British colliery owners and coal merchants seem to be unable to supply the increased demand for coal and coke resulting from the Ruhr situation, as not only has their production of coal reached its probable maximum under existing conditions, but their dock capacity, which is and has been for some time the governing factor in their export trade, is heavily overtaxed. This is due largely to the fact that British dock labor has insisted upon only two 8-hour shifts per day. Strong efforts have been made to put on an additional shift, but so far with but little success, and the whole matter has now been referred to the Industrial Court, which means a probable delay of six months before the matter can be adjusted.

To show the handicap imposed upon the British export trade by their limited ship-loading facilities it was publicly stated by the head of one of the largest South Wales coal shippers that during the last week in February "out of a hundred thousand wagons (cars) employed in the coal field in the transport of coal from pit to port, no less than 70,000 of them, loaded with 700,000 tons of coal, are standing at the collieries, sidings and docks waiting shipment."

British Exports and Production.—British coal exports for January were 5,611,670 gross tons, as compared with 6,070,316 tons in January, 1913; 5,794,770 tons in January, 1914, and 4,020,935 tons in January, 1922.

British production is now ranging from about 5,567,000 to 5,644,000 tons per week, compared with an average of 5,520,000 tons per week in 1913, the year of greatest production; the total production for 1922 was 259,839,000 gross tons, as compared with 286,729,000 tons in 1913.

For the year 1922 British exports were 64,198,384 gross tons, as against 24,660,552 tons in 1921 and 73,400,118 in 1913, the record year.

Ruhr Production.—Production in the Ruhr field in past years and up to Feb. 1, 1923, is given in the following tables, in metric tons:

ANNUAL COAL PRODUCTION IN RUHR FIELD, 1913-1922

1913	114,487,000	1918	96,016,000
1914	98,285,000	1919	71,153,000
1915	86,778,000	1920	84,986,000
1916	94,563,000	1921	91,321,000
1917	99,365,000	1922	93,788,284

MONTHLY PRODUCTION IN THE RUHR COAL FIELD, 1922

January	8,152,763	August	8,336,773
February	7,737,974	September	8,265,688
March	5,014,278	October	8,827,126
April	7,512,646	November	8,536,214
May	8,081,951	December (estimated)	7,900,000
June	7,078,361		
July	7,854,400	Total	93,298,174

For January, 1923, no figure is available, but it is estimated that it was 25 per cent below December; for February the estimated production was 33 per cent of the December output.

In 1922 the total reparation deliveries amounted to some 18,000,000 tons, as against the demands of the Reparation Commission for 22,279,000 tons, while the total output of the German coal field in 1922, outside of lignite, amounted to 130,664,000 tons.

Belgium.—There is a great demand in Belgium for coke and coking coals. The Belgian coke ovens are producing only about 70 per cent of their normal output, owing to the lack of suitable coal. None is being received from the Ruhr and the British coking coals cannot be obtained in sufficient supplies, although in 1922 British exports to Belgium increased to 3,489,419 tons, from 618,066 tons in 1921.

France.—Since Jan. 19 very little coke or coal has been imported from Germany, causing a greatly increased demand for the British product, which, however, cannot be obtained in any increased amount. This has made it necessary for French buyers, including the government, to make inquiry in this country for both coal and coke. France is particularly short of coke and coking coal, reducing metallurgical production, as the supply available is absorbed by contract requirements. A great number of blast furnaces are reported as now being blown out owing to the lack of coke. British coke is now costing about 240 fr. per metric ton, c.i.f. Dunkirk.

British coal exports to France in 1922 were actually in excess of those in 1913 and twice as large as in 1921, the figures being as follows: 1913, 12,775,909 gross tons; 1921, 6,395,651 gross tons; 1922, 13,479,417 gross tons.

Italy.—For the past year Italy's coal requirements have been taken care of by the import of British coal, supplemented by that received from German original sources. Now, however, Italy is looking to this country, especially for gas and coking coal, as shown by inquiries and the actual closing of a fairly large tonnage over the next three months.

Germany.—Germany apparently is in urgent need of large tonnages of industrial coal. For the past year she has been purchasing increased quantities in England, as shown by the following figures of British exports to Germany: 1913, 8,952,328 gross tons; 1921, 817,877 gross tons; 1922, 8,345,606 gross tons.

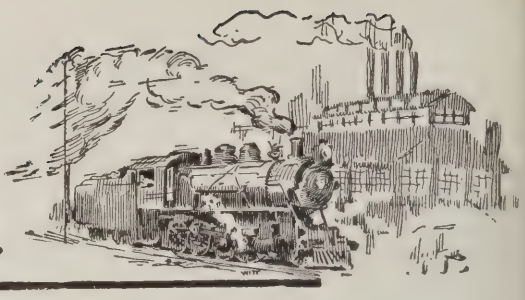
There also is a considerable tonnage of coal from Great Britain that reaches Germany through Holland and it is significant that British exports to Holland increased from 1,787,678 tons in 1921 to 6,067,789 tons in 1922.

Inquiries have been received here for a large tonnage of coal for Germany, said to amount to at least one million tons; one sale of 200,000 tons, over four months, has been reported as closed.

Sweden.—As a result of the European situation, Sweden also has asked for quotations on coal suitable for locomotive fuel, but no actual sales have been reported.

South America.—Owing to the increased demand in Europe, British exporters have cut down their shipments to South America, exports to Argentina having been decreased from 308,078 tons in December, 1922, to 207,786 tons in January, 1923, with a probable further decrease in February.

Inquiries for U. S. coals have been quite numerous from Brazil and Argentina, although but little actual business has resulted up to this time.



As a result of the European conditions, from Feb. 20 to March 12 some fifty-two steamships have been closed for our transatlantic coal and coke trade at rates varying from $2.40 to Rotterdam to $3.50 to West Italy for coal; indications point to an increase in these rates and it is expected that they will reach higher levels, as sharp advances in coal freights from South Wales to other countries already have been made. Of the fixture mentioned, 14 were for West Italy and 28 for Rotterdam-Antwerp.

The export inquiries now being received are principally for gas, coking coals, locomotive coals and coke; current supplies at Tidewater are not equal to the demand, owing largely to shortage of equipment. It is particularly unfortunate that the latter condition exists, as it has given an excuse for advancing prices f.o.b. Tidewater, a rise of over $1 per ton at Hampton Roads in the last two weeks having taken place.

It is greatly feared that the rising prices will tend to retard overseas exports, but with the coming of warmer weather, additional equipment and better movement, the car supply at our mines should steadily improve, which would mean a heavier movement to Tidewater, with a probable reduction of prices, or at least no further rise.

Production and the Market

Weekly Review

As April 1 approaches there is speculation as to the turn prices will take for the coming coal year. On the whole conditions favor a higher level than obtained at the opening of the coal year two years ago. Industrial activity then was on the wane, the country was in the process of deflation and prices of other commodities and labor were declining. Business men were despondent. Today matters are on the opposite course. Industrial activity is gaining momentum, business is optimistic, commodity prices are going up.

Notwithstanding the improvement in general business, bituminous-coal prices are descending as spring approaches. Throughout the winter the ability of the railroads to move soft coal has set the upper limit of output at around 11,000,000 tons per week and prices have slowly dragged downward as urgency of demand declined. The easing off of buyers began in the West and has moved progressively East. Doubtless it would be even more pronounced on the Atlantic seaboard now were it not for the incipient export demand.

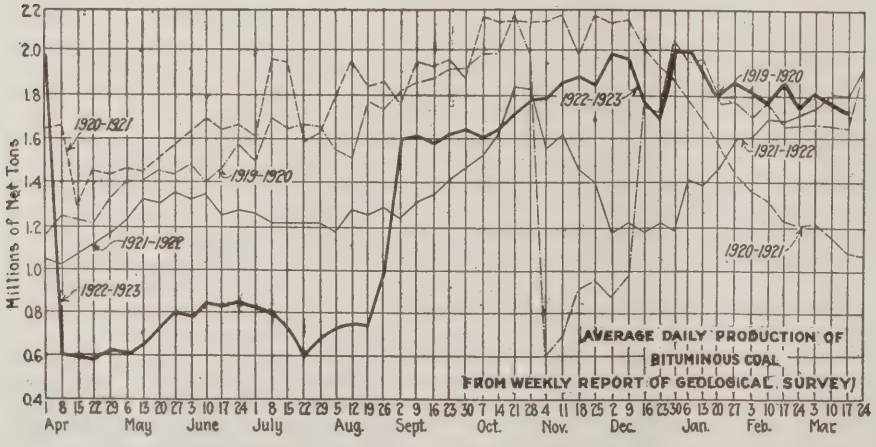
Coal Age Index dropped five points in the week of March 19 to 263, corresponding to an average spot price of $3.19.

Coke for Export in Demand

There is very little talk now of wage reductions in the non-union fields, but for that matter there was little this early in 1921. On the other hand there are companies assuring their non-union men that wages will not be reduced this year. The assurance is opportune, of course, in view of the anticipated drive by the United Mine Workers for the organization of these fields next month.

The possibility of an active export market is hanging over the trade in the East. More than fifty ships have been chartered and a few have been loaded for European ports. The demand occasioned by the cessation of production of coal and coke in the Ruhr is being transferred to this country, although for the most part the inquiries and orders that reach here are founded on apprehension rather than definite and positive want of coal. The recent advances in coal prices for export and in boat rates have disclosed how light the foreign demand really is at this time.

Coke was in good demand for export, it being reported that orders for 25,000 to 30,000 tons had been placed for shipment from either Baltimore or Philadelphia. Connellsville coke was quoted at $12@$12.50 f.o.b. piers with freight charges ranging $5@$6.



Prices Drop in Midwest

As in all other parts of the country, prices dropped in the Midwest. Demand in the Standard district was good for cheap coal. A good deal of attention was being given to the contract situation. In the Northwest industrial trade was fair and domestic demand quiet. Cheaper coal is expected by dealers when Lake navigation reopens.

Central Pennsylvania coals are free to flow uninterruptedly into New England now that most of the embargoes have been lifted. The tonnage moved, however, is not large, buying among the industrials being extremely light.

"Present estimates of soft-coal production for the week ended March 10," says the Geological Survey, "indicate a total output of 10,609,000 net tons, including coal shipped, mine fuel, local sales and coal coked. This is a decrease of 337,000 tons as compared with the revised estimate of 10,946,000 for the week that ended March 3.

"Preliminary reports of cars loaded in the week March 12-17 indicate a further decline in production. Loadings on Monday [March 12] were 38,654 cars as compared with 41,669 cars on Monday of the week before. On

Estimates of Production

Net Tons)

	1922	1923
BITUMINOUS		
Feb. 24 (*b*)	10,402,000	10,324,000

Coal year to date	83,409,000	49,365,000
COKE		
Mar. 3 (*b*)	143,000	402,000
Mar. 10 (*a*)	154,000	366,000
Calendar year	1,294,000	3,527,000

(*a*) Subject to revision. (*b*) Revised from last report.

Tuesday of the present week [March 13] loadings dropped to 31,550 cars. Wednesday's report showed a slight pick-up, but on Thursday loadings fell to 27,955 cars. The total output thus indicated for the week is between 10,400,000 and 10,500,000 tons."

The anthracite situation was easier. Movement increased and the smaller independent producers found it necessary to reduce their prices in order to move coal. Buckwheat was difficult to move and some producers endeavored to get rid of it in conjunction with the movement of the domestic coals. New England and Canada are reported to be badly in need of coal.

Production of coke in the Connellsville region during the week ended March 10 was reported as 280,530 tons, an increase of 2,200 tons over the preceding week.

Midwest Prices Drop Again

Franklin County (Illinois) domestic sizes took another drop in price early this week, drawing other Midwestern coals down with them. The new circular, which went into the mails Saturday, cut lump, furnace, small egg and stove, which means all sizes above 2 in., from $4.75 down to $3.85, leaving all other sizes where they were. Mine-run remains at $3@$3.50, and screenings $2.50@$2.75. Indiana Fourth Vein Lump, which has been quoted at $4, goes down to $3.50@$3.75, all other competing coals drop in proportion.

Even steam demand lay almost dormant as the struggle to unload domestic sizes went on. Good southern Illinois was quoted steadily at $2.50 but a great deal of even the high-grade stuff moved at $2.25 and lesser grades from the southern tier of Illinois counties sagged as low as $1.90 on the Chicago market and $1.75 at St. Louis.

In the Mt. Olive district the failure to move steam coal has tied up several mines and working time is about two days a week. The "Standpatters" are demanding $4 for Mt. Olive 3-in. lump with Franklin County at $3.75. Very little of this is moving excepting on contracts.

In the Standard district the demand for cheap coal has been good, but there is an overproduction and some mines have had to shut down on account of "no bills" of all sizes, but the sizes moving best seem to be 6-in. lump.

Contracts are getting a good deal of attention just now. Cement and brick plants, whose business is rushing, are signing up and a number of railroads have bids out.

* Net tons, f.o.b. mines. † Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 263, Week of March 19, 1923. Average spot price for same period $3.19. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

St. Louis Full of Coal

An unusually quiet market prevailed at St. Louis except during a flurry caused by the temperature falling to 25 deg. above last week. This brought out a lot of small domestic orders, principally for cheaper grades. Wagonload steam also became active. Dealers report a plentiful supply of everything on hand, including a lot of Carterville that was purchased at $5.50 and some in transit that was bought at $4.75, although the prevailing mine price today in St. Louis is $3.75. Retail prices have not been reduced.

Carload steam business in St. Louis was unusually quiet and there was practically nothing going out to the country. The St. Louis market was cleaned up by consignment shipment to Chicago and some Standard screenings sold there for as low as 50c.

Kentucky Watches Lakes and Export

Lake inquiry grew a bit livelier throughout Kentucky during the past week and a good many hopeful eyes were turned eastward at a developing export trade that may drain a good deal of West Virginia coal out of the Kentucky competitive market at $3.25 mine-run, or even a little better. However, prices on most sizes and grades in Kentucky softened a shade. Within the next two weeks the last trace of $5 best gas lump is likely to disappear from Kentucky quotations.

Eastern Kentucky screenings are said to be a shade firmer as a result of relatively small production of block coal.

Northwest Is Inactive

Northwest trade lay nearly dormant during the past week. Weather remained mild in spite of the near-blizzard which swept across the country just below the Lakes. Though industrial demand was fair, the domestic trade was flat. In about a month it is likely that boats will be able to get in and out of most Northwest harbors. Cheaper coal is confidently expected by most buyers after the first cargo arrives.

There remains 4,200 tons of anthracite on the Superior docks, according to reports, but nobody seems to be able to account for that volume. Briquet plants have turned from anthracite to Pocahontas. In Milwaukee traffic jams still have the market nearly empty though a little hard coal has arrived. The local coal shortage has drawn in coke from points as distant as Alabama.

Some Activity in the West

Colorado mines this spring are going after business by making the annual summer price drop $1 instead of 50c. This has started some movement of coal. Wintry weather helped the market during the past week. All mines show an increase in production reaching about 75 per cent of normal. A new tariff between the Rocky Mountain states and South Dakota on the Chicago, Milwaukee & St. Paul and the Chicago & Northwestern railroads has increased the market field for mountain coal.

In Utah running time is now about 55 per cent and the weather has been such that dealers have done a satisfactory domestic business lately. Utah coal suffered a blow, however, in the fact that the Salt Lake route is shifting from coal to oil. This means that oil will displace about 190,000 tons of coal annually.

Trade is flat for the Kansas and Oklahoma fields. The drop last week in Kansas lump had no appreciable effect. Most mines in the Southwest are working less than one-third of the time. Many are shutting down.

Steam Trade Firm in Columbus

The export demand, together with the continued car shortage caused a firmness in the steam trade in the Columbus (Ohio) market. Assigned cars made up a large percentage of the car supply at many mines. Embargoes are holding up shipments, especially on many lines in Michigan and northern Indiana.

Industrial buyers are returning to the Cincinnati market. Lake buyers also have been in evidence, bringing reports of a complete clean-up of several of the docks.

There has been some inquiry in the Pittsburgh district for coal for export, and some sales appear to have been made. It is understood that a cargo of about 10,000 tons of gas coal has been sold.

Production picked up in central Pennsylvania last week, 19,352 cars being shipped, an increase of 1,298 over the previous week, but to offset this, demand fell off and some coal was left standing on siding, unsold.

Car supply improved in the Buffalo market, but demand was slow.

New England Notes Pause in Buying

While the New England market on cars was unaffected, there was appreciably less demand at Hampton Roads. For a time prices advanced 25c. a day until $7.50 was reached, and thereafter the market receded to $7.25 with intimations that $7 would be accepted.

The contract basis on Pocahontas and New River seems difficult to gage. One large producer has named $4 per net ton at the mines as a basis for April, a price that would mean $7 per gross ton f.o.b. vessel at Norfolk, but at the same time other interests are naming $6.50 as a season figure.

The flurry over export inquiry influenced producers of the more favorably known grades in Pennsylvania to hold prices rather stiffly on contract in the hope they might catch some of the overflow demand from Hampton Roads, but

the same interests have now renewed their canvass for season business among home buyers.

New York Interested in Export Conditions

Demand in New York market was slow. More interest was manifested in the export situation than in local conditions. Local houses received many inquiries but high prices and high freight rates caused much delay in placing orders.

In the Philadelphia market there was much improvement in the business closed for overseas delivery and to South America and the West Indies.

There was a strong demand for gas coals in the Baltimore market. The coke market was strong, with home and foreign demand in excess of actual production. Coal exported from Baltimore during the first thirteen days of March was more than double that exported during January and February together.

A total of 2,708,000 net tons of soft coal was moved through North Atlantic ports in February, according to the Geological Survey, as compared with January dumpings, 3,189,000 tons, there is indicated a very slight decrease in the rate of movement, allowing for the difference in lengths of the months. Shipments in February were about the same as in December but were heavier than in previous months and in February a year ago when they totaled 2,625,000 tons.

TIDEWATER BITUMINOUS COAL SHIPMENTS FOR FEBRUARY, 1923
(In Net Tons)

Destination	New York	Philadelphia	Baltimore	Hampton Roads	Charleston	Total
Coastwise to New England	134,000	41,000	99,000	795,000	16,000	1,085,000

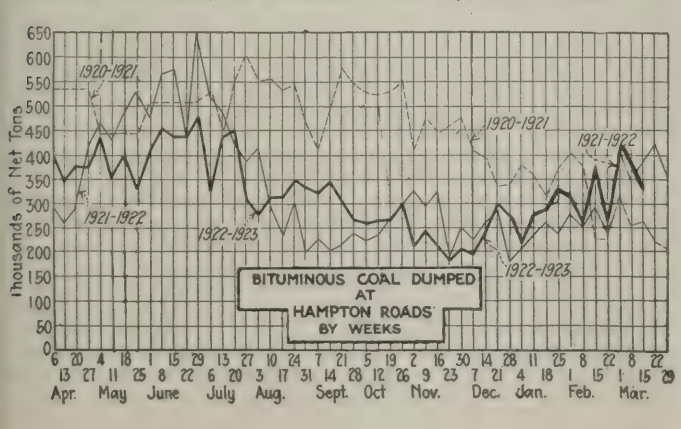
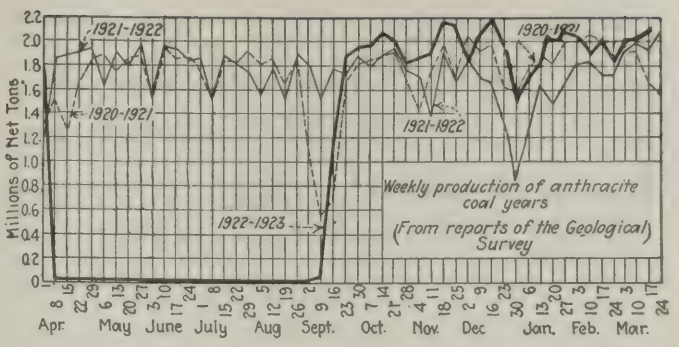
Inside Capes	.....	143,000	129,000	68,000	.....	340,000
Other tonnage	536,000	.....	8,000	218,000	3,000	765,000
Totals	897,000	223,000	267,000	1,288,000	33,000	2,708,000

Anthracite Production Lower

"The production of anthracite in the week ended March 10," says the Geological Survey, "is estimated, on the basis of 39,170 cars loaded, at 2,048,000 net tons including coal shipped, mine fuel, local sales and dredge and washery output. This is a little less than the output during the week preceding.



"The cumulative production for the coal year now nearly closed stands at 49,365,000 net tons, as compared with 83,409,000 tons a year ago, thus bearing out early estimates of 40-per cent deficiency.



"Early returns for the week March 12-17 indicate a slightly higher rate of production and a probable total of 2,100,000 net tons."

Coke

The production of byproduct coke in February was 2,810,000 net tons, as compared with 3,100,000 tons in January. A slight increase was shown in the average daily output. This was at the rate of 83.5 per cent of full capacity. Of the 71 plants in existence, 62 were in operation and 9 were idle.

Despite the short month, the total output of beehive coke in February was more than in January, being 1,482,000 net tons, as compared with 1,478,000 tons.

MONTHLY OUTPUT OF BYPRODUCT AND BEEHIVE COKE IN THE UNITED STATES (a)
(In Net Tons)

	Byproduct Coke	Beehive Coke	Total
1917 monthly average	1,870,000	2,764,000	4,634,000
1918 monthly average	2,166,000	2,540,000	4,706,000
1919 monthly average	2,095,000	1,638,000	3,733,000
1920 monthly average	2,565,000	1,748,000	4,313,000
1921 monthly average	1,646,000	462,000	2,108,000
1922 monthly average	2,374,000	669,000	3,043,000
Dec., 1922	3,063,000	1,233,000	4,296,000
Jan., 1923	3,100,000	1,478,000	4,578,000
Feb., 1923	2,810,000	1,482,000	4,292,000

(a) Excludes screenings and breeze.

It is estimated that the coke production in February required a total of 6,376,000 net tons of coal. This requirement is slightly in excess of the monthly average consumption during the active business year, 1920.

ESTIMATED MONTHLY CONSUMPTION OF COAL FOR MANUFACTURE OF COKE (a)
(In Net Tons)

	Consumed In Byproduct Ovens	Consumed In Beehive Ovens	Total Coal Consumed
1917 monthly average	2,625,000	4,354,000	6,979,000
1918 monthly average	3,072,000	4,014,000	7,086,000
1919 monthly average	2,988,000	2,478,000	5,466,000
1920 monthly average	3,684,000	2,665,000	6,349,000
1921 monthly average	2,401,000	706,000	3,107,000
1922 monthly average	3,411,000	1,056,000	4,467,000
December, 1922	4,401,000	1,945,000	6,346,000
January, 1923	4,454,000	2,331,000	6,785,000
February, 1923	4,037,000	2,339,000	6,376,000

(a) Assuming a yield in merchantable coke of 69.6 per cent of the coal charged by product ovens and 63.4 per cent in beehive ovens.

Foreign Market And Export News

British Production and Prices Show Increase Export Demand Strong

The output of coal in the British mines during the week ended March 3 was 5,566,000 tons, according to a cable received by *Coal Age*. This was within 78,000 tons of the high record for the year.

Quotations for the various grades for the week ended March 17 show a substantial advance over the previous week.

The South Wales market continues strong. Most operators are booked ahead for the balance of the month, while additional inquiries are coming in from France and other countries. There was no improvement in shipping facilities.

Coke is in good demand, both for home consumption and export. French buyers are numerous.

It is reported that the gas companies are endeavoring to make certain changes in their buying policy with respect to contracts for the ensuing year. Under present conditions coal is supplied to the gas works in regular monthly tonnages. This practice has been in force for several years. Previously it was the practice to supply 60 per cent of the required tonnage during the six winter months and 40 per cent during the remaining months of the year. It is said that the gas companies intend to resume this plan of deliveries by inserting a clause to that effect in their new contracts.

Export Movement at Hampton Roads Active

Business at Hampton Roads last week was brisk, with prices slightly on the incline and with increase in export business the feature of the market. Movement in all directions increased, although a temporary dropping off in dumpings took place, due to delayed shipping coastwise.

Movement of coal to Germany and the Scandinavian countries was one of the unusual features of the market, and the trade looked forward to a continuance of this business which is being developed on a rather extensive scale.

The tone of the market was somewhat stronger than in past weeks and the outlook was brighter. The car situation improved, and price fluctuations were not regarded as permanent.

News Items From Field and Trade

ALABAMA

The Pratt Consolidated Coal Co. is making ten new openings near its old workings at Dora and is constructing a spur track connection to move the output.

The American Fuel Co., Birmingham, has been incorporated with a capital stock of $500,000, with $100,000 paid in, and will engage in a general fuel business.

Glen Mary Coal Co., Birmingham, is developing a new mine in Marion County.

The Jagger Coal Co., Birmingham, is electrifying its mines at Prospect, Ala.

The Corona Coal Co. is considering the reopening of its Townley mines, which have been idle for the past two years.

ARKANSAS

The Southwestern Coal Commission was organized at Fort Smith, Ark., Feb. 28, at a meeting of coal operators and representatives of the United Mine Workers of America, District 21, to discuss the agreement, previously signed in Kansas City by operators and workers. John L. Britton, McAlester, Okla., president of District 21, was elected chairman of the commission. Members of the commission elected were for the miners: Dave Frampton, Moberly, Mo., international organizer for the miners, and W. C. Dockerman, Huntington, Ark., for the operators, J. C. Reid, general manager, Cameron Coal Co., Williams, Okla.; Robert Boyd, Central Coal & Coke Co., Hartford, Ark., and P. R. Steward, Fort Smith, commissioner for the coal operators' association.

Passage of a severance tax bill, levying 1 cent a ton on all coal mined in the state, was one of the final acts of the Arkansas Legislature, and the only one affecting the coal industry in the state. An alternate proposal to levy a tax of 1 per cent on the sale price at the mine failed to carry. The proceeds of the proposed tax were to have been used for the support of schools in the state.

COLORADO

The Cambro Mine, of the Co-operative Fuel Co., Denver, located in Boulder County, on the C. B. & Q. R.R., which closed in March, 1922, was reopened in November, 1922.

The Red Ash Mine, owned by Davis, Lewis & Son, Gorham, located in Boulder County, on the C. & S. R.R., which closed in October, 1922, was reopened Jan. 15, 1923.

Hastings Mine No. 5, of the Victor American Fuel Co., Denver, located in Las Animas County, on the C. & S. E. R.R., which closed in July, 1921, was reopened in July, 1922.

The Southwestern Mine, of the Rocky Mountain Fuel Co., Denver, located in Las Animas County, on the C. & S. R.R., which closed in January, 1922, was reopened in August, 1922.

Brodhead No. 10 Mine, of the Temple Fuel Co., Trinidad, located in Las Animas County, on the C. & S. R.R., which closed in March, 1921, was reopened in August, 1922.

The Lambert House bill No. 1 and the Lacy House bill No. 248 are now in the Colorado Senate. One of these bills provides for the **abolishment of the state coal mine inspector's office** and turns it over to the State Utility Commission. The other abolishes the office and puts the work in the hands of the metalliferous department of the state. Both bills are termed extremely malicious by the coal operators. The present system of state coal mine inspection is paid for by the operators, who bear a small tax by the state on each ton of coal mined.

House bill No. 149 in the legislature, **a hobby, it is alleged of the United Mine Workers, provides that every coal miner is required to have a state license** to work underground, that he will not be granted a license unless he has worked underground at least two years. This bill has just been ordered printed and has not come up for passage.

In the Colorado Legislature amendments have been made to the House bill introduced by R. D. Elder, Lake County, providing for the **establishment of a state fuel administration to regulate and control coal and coke fuel prices,** the measure being passed by the House on third reading.

The Mine & Smelter Supply Co., with branches in Denver, Salt Lake City and El Paso, has taken over exclusive representation for the States of Colorado, Utah, Nevada, Wyoming, New Mexico, and Western Texas for Wilson Plastic-Arc Welders and Wilson Color-tipt Welding Metals.

Storage season prices for this year, effective April 1, **have been announced** by the Colorado Fuel & Iron Co., which usually sets the precedent for Colorado. Mine quotations for the Walsenburg and Canon City districts are: Lump: April and May, $5; June, $5.25; July, $5.50; August, $5.75; September, $6. Nut: April and May, $4.50; June, $4.75; July, $5; August, $5.25; September, $5.50. In the Trinidad district prices are: Lump: April-July, $4.50; August, $4.75; September, $5. Nut: April-July, $4.25; August, $4.50; September, $4.75.

ILLINOIS

The Shuler Coal Mining Co., at Alpha, Mercer County, **is developing its No. 1 mine,** a new property, on the Burlington R.R.

Hickory Hill Coal Co., at Equality, Gallatin County, **reopened their mine,** closed in October, 1921, located on the Shawneetown branch of the L. & N. Ry.

Gallatin Coal & Coke Co., at Equality, Gallatin County, have **reopened their mine,** located in the L. & N. Ry., which was closed in October, 1921.

Big Creek Coals, Inc., at Harrisburg, Saline County, **has reopened mines Nos. 2, 4, 5 and 6,** located in the Big Four. Mine No. 2 was closed in October, 1921; Nos. 4 and 5 in August, 1921, and No. 6 in December, 1920. This company has another mine, No. 3, also located at Harrisburg.

A new coal company, incorporated under the name of the **Utilities Coal Co.** has taken over the No. 18 and No. 19 mines operated by the Peabody Coal Co. at West Frankfort, and owned previously by the By-Products Coke Corporation, of Chicago. The new company has John F. Gilchrist of the Commonwealth Edison Co. as its president and Stuyvesant Peabody, head of the Peabody Coal Co. as its vice-president. The Peabody company will continue to operate the mines.

The Globe Coal Co., of Chicago, has issued formal announcement of the transfer of the Western sales agency for Pittston anthracite from Williams & Peters to itself, as previously reported in *Coal Age*. After April 1 the Globe company will handle all Pittston all-rail anthracite west of Pennsylvania and will continue the sale of the Hudson Coal Co.'s Lackawanna coal west of Indiana. It also was announced in New York that the Buffalo Lake tonnage will be handled by the Pittsburgh Coal Co. of Wisconsin, and the C. Reiss Coal Co. The following changes in the personnel of the Globe company are announced: F. W. Barrett, who has been connected with the company in various capacities for a great many years, will be vice president, succeeding E. S. Van Sant, retired; F. N. Pease, who for a long period of years has been the Western representative of Williams & Peters, will be secretary; A. R. Loring, who has acted in the past as assistant treasurer, will be treasurer, succeeding Willis D. Maier, retired; L. W. Sanborn, who has been associated with the company for many years, will be assistant treasurer.

The No. 12 mine of the O'Gara Coal Co. near Harrisburg, **will be rebuilt** during the coming six months. The mine was shut down March 1 to permit the construction of a steel and concrete tipple and the installation of some new machinery. Haulageway grades underground will be leveled so that 2 per cent will be the maximum for any part of the mine and a good deal of new steel will be laid. Four electric gathering locomotives and several more shortwall coal cutters will be added to the production equipment. Heretofore mules have been used extensively for gathering. After the improvements have been made few mules will be left. It is expected the potential capacity of the mine will be raised from 1,000 tons a day to approximately 2,000 tons.

The Southern Mining Co., of Danville, has incorporated with a capital of $150,000. The incorporators of the new company are Richard Y. Hoffman, Walter L. Millner and Kenneth M. Fiske.

On Feb. 28 the No. 2 mine of the **Groveland Coal Co.,** which is 202 ft. deep and whose average coal thickness is 4 ft. 4 in. **hoisted 2,115 cars in exactly 8 hours,** which netted 2,932 tons of coal.

M. S. Ketchum, dean and director of the College of Engineering and Engineering Experiment Station, University of Illinois, has announced that **applications for appointment to the research graduate assistantships** which are maintained by the experiment station of the university **will be received up to April 1, 1923.** The university maintains fourteen of the assistantships and two others have been established under the patronage of the Illinois Gas Association. These appointments are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics or applied chemistry.

The Citizens Coal Mining Co. has made a stock dividend of 650 per cent, basing this stock issue on accumulated surplus and undivided profits. The company increases its capital from $60,000 to $300,000.

The executive committee of the Illinois **Mining Institute** in Springfield March 10, decided **to hold the summer meeting of the Institute on a boat trip on either the Illinois or the Mississippi River.** W. J. Gates, of St. Louis, was made chairman of the entertainment committee, which indicates that the institute will have a successful and satisfactory outing. John E. Jones, safety engineer of the Old Ben Coal Corporation, was chosen to succeed the late Prof. H. H. Stoek on the executive committee.

INDIANA

Warren S. Blauvelt, president of the Indiana Coke & Gas Co., of Terre Haute, believes it is possible, by allowing a commission on freight bills graded to encourage summer shipment, **to establish a system of freight rates on coal and coke** which would adequately reward consumers, dealers, and shippers for co-operating to utilize existing mine and railroad equipment uniformly throughout the year, and thus reduce the costs of mining, transporting and distributing fuel, with consequent material reduction in price to consumers.

Three new provisions are contained in the codification of the state mining laws introduced as a bill in the General Assembly by Senator Clem J. Richards, a coal operator. One provision seeks to protect miners from the danger of oil and gas wells that are drilled in concrete or piping. Another governs the placing and use of electrical appliances in mines, and the third deals with the manner in which worked-out parts of mines shall be sealed off from other parts. The bill introduced previously by Senator Richards providing for a state mining department, separating the present state mining inspection work from the State Industrial Board, is not a part of the codification bill. The proposal however, has the unanimous approval of the codification commission, Governor McCray, the Industrial Board and operators and miners in the state, according to Carey Littlejohn, state mine inspector. The bill has passed the Senate by a vote of 40 to 3 and has gone to the House.

Clem G. Richards, Senator in the Indiana General Assembly, is being boosted in the western part of Indiana **for the nomination for Governor** at the next primaries. Mr. Richards is a coal operator of Terre Haute.

The Big Four contemplates starting actual **construction of its $5,000,000 terminal yards just north of Terre Haute** some time this year, according to a Big Four official. The company also is making arrangements whereby coal and freight trains from and to the Evansville, Indianapolis & Terre Haute R.R. will be constructed over the Chicago, Milwaukee & St. Paul belt line east of Terre Haute, thus eliminating all freight movement through the city and permitting a **much speedier service for coal and freight** trains. The company also contemplates constructing a cut-off from the new yards to the bridge of the C. M. & S. P. over the Wabash and from there to some point on the main line between St. Mary-of-the-Woods and Sanford. This will eliminate a heavy grade between Terre Haute and St. Mary and dispense with all coal and freight movement through Terre Haute.

The Love Coal Co., Anderson has been incorporated with a capital of $50,000, to engage in coal mining; directors, Eldra O. Love, E. C. Love and L. B. DeSanctis.

A second election in District No. 11, U.M.W.A., the Indiana district, held because of insufficient pluralities in the first election, made no important changes in results. The complete roster of officials elected for the new term follows: W. D. Van Horn, Terre Haute, international board member; John Hessler, Terre Haute, district president; T. I. Roberts, Terre Haute, district, vice-president; William Mitch, Terre Haute, district secretary-treasurer; Elmer Whitman, Princeton, board member subdistrict No. 1; Harvey Cartwright, Bicknell, board member subdistrict No. 2; James H. Terry, Dugger, board member subdistrict No. 3; Dave Jones, Terre Haute, board member, subdistrict No. 4; William Lackey, of Bicknell, and Joe Wallace, of Terre Haute, assistants to the legal department; John R. Morgan, of Linton; Earl Jones, of Terre Haute, and Roscoe Barrett, of Shelburn, district auditors and members of the credential committee, and Clyde Webster, Terre Haute; Joe Edwards, Bicknell, and Richard Roberts, Linton, district tellers.

KANSAS

The old Morley coal mine near La Cygne, which was originally dug and operated by the Morley Bros., in the early 80's **is to be reopened** and operated by an organization consisting of Jake Demarrs and others. The mine shaft has been sunk to a depth of 98 ft.

KENTUCKY

Plans to install radio sending and receiving sets in Cincinnati, Lexington and Hazard with a network of receiving stations throughout the coal field in eastern Kentucky to facilitate communication are being made by the Hazard Coal Operators' Exchange representing coal operators in eastern Kentucky. The object is to keep isolated mine offices posted on prices and market conditions at a big saving in long distance telephone tolls.

Coal properties of the state are to be taxed more severely in 1923, the State Tax Commission having ordered a levy increase of $81,235,000 for the year, and of this $27,550,000 is to be added to the coal assessments. So much talk is heard relative to coal not paying its proportional tax that the matter is being pushed, especially by the press, and it looks as if the next legislative session might pass a coal-tonnage tax. Operators have fought this movement for years.

Considerable construction is planned by Eastern Kentucky mining companies this year. It is reported that the Imperial Elkhorn Coal Co., at Sergent, Ky., plans erection of 100 additional miners' homes; and the Consolidated Fuel Co. will add 50 at Dalna, while the Apex Coal Co. plans a new commissary along with other buildings. It is further reported that some of the companies are planning to enlarge facilities for larger capacity production, realizing the need of a high rail rating in order to get out much coal when car shortage is chronic.

According to a press statement the State Tax Commission has been busy **trying to explain how come that Henry Ford paid $15,000,000 for 30,000 acres of land** and improvements in Pike County, when **Pike's entire 423,782 acres is assessed at only $19,466,686.**

According to preliminary figures issued by the Kentucky Department of Mines on March 5, **coal output of the state in 1922 was 41,293,933 tons,** or 11,016,274 tons greater than in 1921, in spite of mine and rail strikes, which hampered production for some time, and in spite of a year of poor car supply. Harlan County, with 6,128,361 tons, led the state. District No. 6, composed of Letcher, Perry and Knott counties, showed 7,882,613 tons. In western Kentucky District No. 1, including Webster, Hopkins, Christian, Henderson and Union Counties showed 7,408,238 tons. It was reported that 46,558 men were employees as against 39,971 the previous year.

Several water power projects for development of cheap electric current in the state are of interest. The Louisville Gas & Electric Co. and City of Louisville are after rights for producing power at the Ohio Falls, Louisville, and on the Cumberland River, near Burnside, Ky., while a group of Indianapolis men are also after the Burnside project.

MINNESOTA

A bill has been introduced in the Minnesota Legislature **requiring coke** offered for sale **to be free from foreign substances and thoroughly dry** when weighed.

MISSOURI

Four farms, comprising **376 acres were purchased** early in March by representatives of the **Glasgow Mining and Manufacturing Co.** The purchase was made in connection with the **new coal field development work** now in progress **by the Kansas City Power & Light Co.,** and the land will be used by the company.

A large coal deposit has been located on the farm of John Hobein, two miles south of Drake in Gasconade County. The vein is close to the surface.

Norman Holt, who has been prospecting for coal on the Dilley farm, near De Witt, **has found a vein of fine quality coal** overlaid with a layer of slate that will make it safe for mining purposes. Work will be continued to bring the mine to a state where operations can be continued and coal gotten out for market purposes on a paying basis.

NEW YORK

John M. Ross has been named vice-president of the Coal and Iron National Bank, New York City, effective April 1. Mr. Ross has been recently identified with the Lowry National Bank of Atlanta, Ga., as vice-president. He is well known in New York banking circles, having for a time prior to the war been Atlanta representative of the National City Bank of New York. After the war Mr. Ross went to the Guaranty Trust Co., becoming assistant treasurer.

Directors of **Burns Bros. have set April 9 for a special meeting** of stockholders at which the recently announced plan for recapitalizing the corporation will be acted upon.

Announcement is made that the **exclusive license to manufacture and sell the Mitchell electric vibrating screen has been acquired by the C. W. Hunt Co., Inc.,** New York City, designers and manufacturers of material handling equipment.

OHIO

A strike of about 900 miners at the Sugar Creek mines of the Ohio Collieries Co., near Athens, was declared last week because of the method of dividing work. Men "marked up" at one mine refused to go to work unless men at other mines received their proportion of work. The miners have been having about one-third employment for some time. Officials of the United Mine Workers, Ohio district, have been called upon to settle the trouble.

Effective March 1, **John J. Masterson** has been appointed manager for the Pittsburgh Coal Co., at Akron, with office in Second National Building, succeeding Robert E. Frazer, who has been advanced to manager of the company's New York office.

OKLAHOMA

The Oklahoma Coal Operators' Association has signed a **contract renewing the existing wage scale** with the United Mine Workers of America, according to a statement of John L. Britton, district president of the mine workers.

The Union Tractor Co., of Coffeyville, Kan., has obtained leases on a large acreage of coal land near Oologah, and it is announced that the company will extend its electric line to the district in the near future and develop the coal. It is planned to open several mines at once.

The Central Coal & Coke Co., of Kansas City, is planning to develop a large coal field in the vicinity of Vinita. It will be a steam shovel proposition.

PENNSYLVANIA

The Lehigh & New England R.R. has announced that it **will receive bids for the following anthracite locomotive fuel:** 450 gross tons of pea coal and 60,000 gross tons of No. 1 buckwheat coal. Bids must be submitted and addressed to E. Hughes, purchasing agent, rooms 612-614, 437 Chestnut St., Philadelphia, Pa., by noon, March 29, and they will be opened at 3 p.m. on that day.

Robert Johnson, mine inspector of the **eighth anthracite district,** reports seven fatal accidents during 1922 among a total of 9,409 men and boys employed in and about the mines. **Coal produced totaled 2,006,957 tons,** 1,715,230 tons of which was shipped to market. Owing to the six months' strike the number of days worked averaged from 121 to 156.

Shipments of anthracite in February, as reported to the Anthracite Bureau of Information, Philadelphia, amounted to 5,951,713 gross tons, as compared with 5,239,014 gross tons during the corresponding month last year—an increase of 712,699 tons, or 13.6 per cent. The record for February of this year is second only to that of February, 1921, when the peak shipment for that month was established, 5,966,101 gross tons being shipped to market. With only twenty-four week days, two of which were legal holidays, bringing the working time during that month to 22 days, February shipments of this year were exceeded by the preceding month of January, when there were 26 working days, by only 720,109 tons, or 10.8 per cent. The daily shipments in February were 270,532 tons, as compared with 256,608.5 tons in January. Shipments by originating carriers were as follows in gross tons:

	February 1923	January 1923
Phila. & Reading....	1,206,538	1,381,359
Lehigh Valley	1,097,351	1,093,052
Jersey Central	521,430	588,093
Lackawanna	957,612	1,038,719
Delaware & Hudson.	629,514	741,739
Pennsylvania	483,466	596,989
Erie	712,210	750,277
N. Y., O. & W.....	169,176	178,072
Lehigh & New Eng.	174,416	303,522
	5,951,713	6,671,822

A bill that would tax for state purposes **"all coal other than anthracite"** was introduced in the House by Representative Walter W. Kohler, Lackawanna County, on March 12. It provides for a 1½-per cent tax on the value of coal when washed, screened or otherwise prepared for market, for coking or other use. The tax thus applied to bituminous is the same as now provided for anthracite coal. The bill follows closely the provisions of the anthracite tax law relative to the making of reports to the Auditor General, the payment of the tax, penalties for violation.

Senator Albert Davis introduced a bill on March 12 providing for **compensation for loss of life or property due to surface subsidence caused by the mining of coal,** minerals or other materials from beneath the surface of lands within the state.

Senator Albert Davis, Lackawanna County, on March 13 offered in the Legislature two measures, one creating an **anthracite mine-cave fund** and the other the **anthracite municipalities fund.** Both bills will be introduced in the House by Representative David Fowler, Lackawanna. The mine-cave fund bill appropriates 25 per cent of the anthracite tax collected annually to the use of the commission. This money is to be placed in the anthracite mine-cave fund of the State Treasury. The measures provide that the **anthracite municipalities fund's 50 per cent of the anthracite tax revenues shall be taken from the tax moneys after 25 per cent has been deducted from the tax moneys for the anthracite mine-cave fund.**

The United Mine Workers of America and organized labor generally are behind **a new workmen's compensation measure** introduced in the State Senate March 12 by Senator Joyce, of Luzerne. It raises the maximum weekly compensation to $20 and fixes $7 as the minimum. In total disability cases compensation would run during the period of disability and in a partial disability case a period of five hundred weeks is provided.

Insufficient facilities to ship coal was reflected in the **output of the mines in the central Pennsylvania field during February** when the total output **was 69,287 cars,** as compared with 82,835 cars in January. However, the production was slightly larger than the corresponding month in 1922, when the output was 67,255 cars. It is reported that the railroads are closing contracts at prices around $2.50 to $3.

So drastic is the slump in the coal business in Somerset County that the **mines in the vicinity of Meyersdale,** including the Statler Coal Co., the Schell Coal Co. and others, **have closed down indefinitely.** Some of the mines are working short time, filling orders as far as the car supply, which is very limited, will permit.

George S. Baton, Frank W. Byrne and R. H. Jamison were appointed **receivers of the American Coke Corporation,** with offices in Pittsburgh, by the U. S. District Court March 5 after a bill in equity had been filed against the corporation by the Union Explosives Co. Bond of the receivers was fixed at $50,000. The explosives company charges that the defendant corporation owes it $4,600 for merchandise delivered. The assets of the coke company, according to the bill, are in excess of the liabilities, but it is asserted that some creditors are threatening suits

and the property is subject to judgments and executions. The corporation's plants were shut down for 10 months in 1922, according to the bill, but are now in condition to operate in full for the first time in two years.

District No. 9, U. M. W. A. has opened headquarters in the Plaza Theatre Building, Brownsville, for the purpose, it is believed, of endeavoring to hold together the membership gained in the Connellsville coke region during the past year.

The Department of Internal Affairs has just issued **a bulletin by the Bureau of Topographic and Geological Survey dealing with coal beds in southern Somerset County**, by J. D. Sisler. The report, covering twenty pages, describes the distribution, thickness and character of the coal beds of the Wellersburg, Berlin-Salisbury and Confluence-Johnstown basins. The report contains thirty analyses, most of which have been made in the last five years, and some of which are now published for the first time. The information in this report is based on field work, most of which has been done during the past two years.

R. V. Norris, consulting engineer, Wilkes-Barre, **has taken his son, R. V. Norris, Jr., in as junior partner**, and the firm will hereafter be known as R. V. Norris & Son. The new member is a graduate of Yale, Ph.B., and Columbia School of Mines 1917, E. M. Since graduating he has been assistant colliery superintendent and later mining engineer for the Lehigh Coal & Navigation Co., lieutenant of engineers in the A. E. F., in France, and junior and senior accountant in Los Angeles. He will attend to much of the routine work of examination and calculation.

Bituminous coal companies incorporated at Harrisburg recently were: **M. & N. Coal Co.**, Curwensville; capital, $50,000; treasurer, L. C. Morris, Clearfield; incorporators: D. G. Mahaffey, F. C. Mahaffey, of Mahaffey, and H. J. Houston, Curwensville. **Renwick Fuel Co.**, Ligonier; mining coal and manufacturing coke; $300,000; A. K. Renwick, Ligonier, treasurer, who with W. E. Brown and L. L. Tosh, Ligonier, incorporated the company. **Logans Ferry Coal Co.**, New Kensington; mining, buying and selling coal and manufacturing coke; $100,000; Frank E. Pratt, 208 Charles Avenue, New Kensington, treasurer. Incorporators: Robert M. Young, 338 Fourth Street, Parnassus; Edgar Earney, Arnold, and W. D. Sharpe, Arnold. **Grampian Coal Mining Co.**, Clearfield; $35,000; incorporators, A. K. Wright, Clearfield, treasurer; George R. Bigler and Ruth Spencer, Clearfield. **B. M. Coal Co.**, Uniontown; mining coal and other minerals; $15,000; incorporators, John R. Best, Uniontown, treasurer; William G. Miller, Indian Head, and Pauline Best, Uniontown.

State charters have been issued to the following coal companies: **Shamokin Anthracite Reclaiming Co.**, Reading; capital, $10,000; treasurer, C. H. Price, 1403 Hill Road, Reading; incorporators, C. H. Price, Clarence L. Noecker, Shoemakersville, and William V. Hassler, Wernersville. **H. J. Thomas Coal Co.**, St. Marys; acquiring coal and coal lands and mining; capital, $30,000; incorporators, G. B. Straub, St. Marys, treasurer; H. J. Thomas, Kittanning, and I. J. Meenan, St. Marys. **Oakdale Coal Co.**, Oakdale, mining coal and manufacturing coke; capital, $50,000; incorporators Valentine Kirch, Oakdale, treasurer; J. G. Schreiner, Pittsburgh, and Anton Kirch, Pittsburgh. **McKeesport Coal & Coke Co.**, Pittsburgh, mining, buying and selling coal and manufacturing coke; capital, $600,000; incorporators, H. A. Davis, Solway street and Shady avenue, Pittsburgh, treasurer; Whitney Warner, Cleveland, Ohio, and F. C. Thompson, Dormont, Pa.

TEXAS

The Dillard-McCain Oil Co., drilling a test for oil one mile north of Whitesboro, **struck a rich vein of bituminous coal** at a depth of 500 ft. The coal has been analyzed and declared of good quality, and borings are now being made to determine if the vein is of sufficient thickness and extent to justify sinking a shaft for mining it.

C. W. Osborne, president and manager of the O. K. Lignite Co. of Dallas, **has made arrangements to develop 600 acres of coal land near Garrison.** The company is now making arrangements to install a hoisting engine and small boilers, as well as mine cars, and it is estimated that the daily output will be five carloads.

UTAH

The town of Huntington mines its own coal as a municipal enterprise. The little town is located near the coal field south of Salt Lake City. A federal license had to be first secured before the enterprise could be started on a municipal basis.

The Rocky Mountain Coal Co., of Salt Lake City, with 500,000 shares of preferred stock at $1 and 1,000,000 shares of common stock with no par value, **has been granted permission** by the Utah Securities Commission **to sell 100,000 shares of 8 per cent cumulative non-voting preferred stock** convertible into first mortgage bonds. The stock will be disposed of only through licensed agents operating in the state. It is estimated that the cost of opening up the company's property will be $277,000.

The Pahvant Coal Co. has received permission from the Utah Securities Commission **to sell $600,000 worth of first mortgage, 7 per cent 20-year bonds**, subject to a discount of not more than 20 per cent, provided that the company gives one share of common stock at a par value of $1 with each share of bonds sold. The money received in payment is to be trusted, subject to release of the commission. The basic assets of the company consist of coal properties in Carbon County. The capital is $2,000,000 in 2,000,000 shares of par value of $1.

WEST VIRGINIA

The Chippewa New River Coal Corporation, of Washington, D. C., has been granted a charter of incorporation and will operate in Raleigh and Fayette counties. The company has an authorized capital stock of $1,000,000. The incorporators are George L. Miller, of Beckley; Hilton W. Robertson, Francis A. Crawford, Joseph T. Saylor and Carl T. Crawford, of Washington.

The Clarksburg Big Vein Coal Co., Clarksburg, capital $100,000, has been incorporated by John P. Kelley, O. L. Billingsley, James J. Killeen, James P. Tierney and E. B. Templeman, all of Clarksburg.

The Hess Coal & Coke Co., with an operating mine at Granville, along the Monongahela River two miles north of Morgantown has been sold to Frank L. Bowman and Fred Troph, of Morgantown. The property involved in the sale consists of 100 acres of Sewickly coal land, 12 acres of Pittsburgh coal land and an operating mine with a capacity of 15 cars daily. This is the second purchase of coal property by the Bowman-Troph interests they having purchased the Andrew mine, adjoining the Hess workings, only a short time ago. The mines will be operated under the name of the troph Coal Co.

The Piedmont Coal Co., Huntington, with a capital of 20,000 shares without par value, has been incorporated by C. W. Stricklan, Roy H. Cunningham, G. C. Garred, James E. Hart and E. E. Winters, Jr., all of Huntington.

The Island Creek Coal Co. declared an extra dividend of $3 a share on the common stock in addition to the regular quarterly of $2, both payable April 2 to stock of record March 26. The regular quarterly dividend of $1.50 a share was declared on the preferred, payable the same date.

WYOMING

The policy committee of District 22, United Mine Workers of America, and the operators of southern Wyoming **accepted the existing agreement as a basis for the coming year** beginning April 1. It was less than 15 minutes after the men had gotten together that they signed a contract. Among those in attendance at the meeting, held at Cheyenne, were P. J. Quealy and Gomer Reese, of Kemmerer; Thomas Russell, of Diamondville; John Giorgis, of Cumberland; E. C. Brooks and Glenn Knox, of Rock Springs, and Martin Cahill, George Young and James J. Morgan, representing the miners' union. Conferences with the northern operators have not yet been held, but it is believed that a similar plan will be worked out in short order.

CANADA

Senator Raoul Dandurant, government leader of the Canadian Senate, **introduced a bill** on March 9 to give effect to an order in council that had been passed by the late Government, **setting aside the Hoppe coal areas, in Alberta, as a Government coal reservation.** Senator Dandurant stated that the reservation could not be set aside without the consent of Parliament, and the bill was introduced for that purpose. The Hoppe coal areas were granted in 1912, and cancelled during the war, because of non-payment of rentals. In 1919 the Government withdrew them from location, by an order in council, and set them aside for a Crown coal reserve. The Hoppe areas are situated in the Smoky River district, in central western Alberta, and contain seams of high-grade coal running from 4 to 17 ft. in thickness. The grade of the coal ranges from bituminous to semi-anthracite. At the present time there is no railway connection with the field.

Operating profits of the Inter-Colonial Coal Mining Co. for 1922 are lower by $25,000, at $135,475, according to a statement submitted at the annual meeting in Montreal. Surplus, after payment of $15,253 preferred dividends and $40,000 common dividends is $29,131, compared with $47,922 in 1921. Total surplus, however, is higher at $340,511, compared with $311,380 in 1921. The output of coal for the year was 135,508 tons against 150,491 tons for the year previous.

WASHINGTON, D. C.

The case of the **J. M. MacDonald Coal Mining Co.** of West Virginia, **against the United States was submitted on briefs** to the U. S. Supreme Court on March 12. This case involves the right to claim from the United States the difference between prices fixed by the President under Section 25 of the Lever Act and prices which the coal company claimed would be necessary to cover the cost of production plus a fair profit.

Traffic News

The concerted effort of most railroads serving Indiana and Illinois to put into effect **a new plan of rating mines for cars is getting some results.** Already the Pennsylvania R.R. has made tentative agreements with all its Indiana mines and with most of those it serves in Illinois to abide by ratings to be made by a railroad board and to accept cars on a round-robin system in each field served. The plan provides that if any mine owner feels aggrieved, the production of his mine during the ensuing six full days shall be totaled, divided by six and the result accepted as the daily capacity of the mine. Agreement has not been reached yet by Illinois and western Kentucky operators with the Illinois Central and the Louisville & Nashville, which serve both Illinois and western Kentucky, and with the Burlington, which taps parts of Illinois. Many Illinois operators, especially those in the southern Illinois field, insist the carriers' proposed plan of abritrary rating by a railroad board is unfair and too rigid. A counter proposal by certain sections of the state is said to be in preparation for the next joint conference with the roads on March 23.

Directors of the **Louisville & Nashville R.R. declared a stock dividend of 62½ per cent** on the outstanding $72,000,000 capital on March 15, payable May 7 to stock of record April 16. This increase of $45,000,000 will bring the total capitalization up to $117,000,000. The regular cash dividend of 2½ per cent was declared in advance, payable Aug. 10, to stock of record July 17.

The carriers in presenting their side of the issues involved in the matter of **Ohio coal rates** and in the case of the **Southern Ohio Coal Exchange vs. the Chesapeake & Ohio** and other carriers, among other things state: "The commission should order carriers to remove the advantages and preferences shown to exist in favor of Ohio coal shippers and Ohio coal originating fields and interstate commerce in Ohio and the prejudice and discrimination shown to exist against coal shippers and coal originating fields in Pennsylvania, Maryland, West Virginia, Kentucky, Virginia and Tennessee, the preference and advantage in favor of Ohio consumers of Ohio coal and the discrimination and prejudice shown to exist against consumers of Ohio coal located in Pennsylvania, Michigan and Indiana; and the preference and advantage in favor of interstate commerce in Ohio and the discrimination and prejudice shown to exist against interstate commerce by putting into effect between Ohio coal originating points and Ohio destinations rates made in accordance with the plan proposed by Eastern carriers and approved by the commission."

A report, adverse to the contentions of the Baltimore & Ohio, Norfolk & Western, Chesapeake & Ohio and Louisville & Nashville has been made by Interstate Commerce Commission Examiner Bardwell, in the matter of divisions between carriers of rates on bituminous coal to destinations in Michigan, Ohio, Indiana, Illinois and Wisconsin. The examiner finds that the **divisions as increased by Ex Parte 74 from the inner and outer crescent districts to points in Michigan and other states are not in-**

equitable or otherwise unlawful. "The historical method of making divisions," says the examiner's report, "resulted in respondents' divisions being increased on Aug. 26, 1920, by greater percentages than those of petitioners were increased, but the additional revenue accruing to the respondents from this cause was more than offset by the increase in their operating expenses resulting from the higher freight rates on fuel coal, from which petitioners suffered no corresponding disadvantage. Assuming, as we must on this record, that the divisions in force on Aug. 25, 1920, were just and equitable, it is impossible to escape the conclusion that the application of the historical method to the rates as increased under Ex Parte 74 did not result in divisions which were unreasonable or unfair to the petitioners."

Seventeen large coal companies of Illinois have filed a complaint with the Illinois Commerce Commission against eleven railroads as to excessive freight rates and they have asked that the commission order a reduction for coal in carload lots. **The operators ask for a reduction of from 20c. to 40c. a ton in carload lots.** The complaint of the mining companies is to the effect that the mines are located within a radius of 20 miles from East St. Louis and practically the same distance from St. Louis, which is just across the Mississippi River, and that the rate of 91c. per ton, now charged, is unreasonable and discriminatory. Eighty per cent of the coal used in St. Louis comes from the district in which the complainants are situated. A similar suit was filed some time ago by the St. Louis Coke & Chemical Co., of Granite City, against 26 carrier lines.

The application of the Toledo, St. Louis & Western R.R. asking permission to continue the rates on anthracite and smithing coal, coke dust and screenings from points in Illinois and Ohio to points in Illinois, Indiana, Michigan, Ohio and to St. Louis, without observing the provisions of the long and short-haul section of the Interstate Commerce Act, **has been denied,** effective July 16.

The application of the Delaware & Hudson R.R. for authority to continue the rates on anthracite coal from points in Pennsylvania to points in New York and Vermont, without observing the provisions of the fourth section of the Interstate Commerce Act, **has been denied,** effective July 16.

The Coal, Coke & Iron Ore Committee, Central Freight Association Territory, announces a public hearing, 10 a.m., March 29, Chamber of Commerce Building, Pittsburgh, **to consider advance in rates on bituminous coal,** carloads, from mines on Sandy Valley & Elkhorn, Long Fork and Millers Creek railroads, to stations on T. St. L. & W., Trilla, Ill., to East St. Louis, Ill., inclusive, from $3.72 per net ton to combination of locals, on account of no movement.

The Coal, Coke & Iron Ore Committee, Central Freight Association Territory, announces a public hearing, 10 a.m., March 29, Chamber of Commerce Building, Pittsburgh, on **cancellation of rate on bituminous and cannel coal,** carloads, to Carbondale and Anna, Ill., for Illinois Central R.R. delivery, from mines in the Cumberland-Piedmont and Gauley regions of the B. & O., on account of no movement of coal. The present rate is $4.54 per net ton.

The Coal, Coke & Iron Ore Committee, Central Freight Association Territory, announces a public hearing, 10 a.m., March 29, Chamber of Commerce Building, Pittsburgh, **to consider advance in rate on bituminous coal,** carloads, from mines on the Sandy Valley & Elkhorn,, Long Fork and Millers Creek railroads, to Pt. Pleasant, W. Va., via the B. & O., from $3.14 per net ton to combination of locals, on account of no movement and rates are obsolete.

The Coal, Coke & Iron Committee, Central Freight Association Territory, Pittsburgh, announces a public hearing, 10 a.m., March 29, Chamber of Commerce Building, Pittsburgh, **to consider advance in rates on bituminous coal,** carloads, to Bartles and Superior, Ohio, via Detroit, Toledo & Ironton R.R., from mines on Sandy Valley & Elkhorn, Long Fork and Millers Creek railroads, from $1.70 per net ton to $2.14 per net ton, to eliminate Fourth Section violation.

An embargo placed Jan. 19 by the **Philadelphia & Reading Ry.** against shipments of bituminous coal for various consignees at Port Richmond Piers, Philadelphia, Pa., was **entirely canceled** March 9.

An embargo placed Feb. 15 by the **New York Central RR.** against all shipments of coal for the New York & New England Cement & Lime Co., Hudson, N. Y., was **entirely canceled** March 10.

The Salt Lake & Utah R.R. (Orem line) has filed a complaint with the I. C. C. **asking that the road be made a party to a tariff under which coal from Utah Railway points is shipped to Nevada and California.** It is charged that at present shippers and receivers of coal in Utah, Nevada and California are subject to unjust, unreasonable, prejudicial and disadvantageous situations, which constitute violations of Sec. 2 and 3 of the I. C. C. Act. The complaint goes on to say that the Utah railway, which terminates at Provo, refuses to grant the complaining company permission to enter into the haul of coal from mines in the Castle Gate district. It is charged that there is an agreement between the D. & R. G. Western Ry. and the Los Angeles & Salt Lake road by which these companies are to haul coal to Salt Lake City and Ogden for routing to Nevada and California points. The petitioning company requests as equal chance at a routing with the Utah railway and proposes that the routing from the coal field be the Utah Railway to Provo; Salt Lake & Utah Railroad to Salt Lake; Bamberger Electric to Ogden and the Southern Pacific to points farther West.

Asserting that the assigned-car practice on the Monongah division of the B. & O. is playing havoc with commercial coal operations five coal companies have addressed an appeal to the I. C. C. charging that **their mines have been supplied with only 30 per cent of their requirements for several weeks** and that mines with contracts for railroad fuel are being favored. The petitioners are the Lambert Run Coal Co., the Delmar Coal Co., the Hughes Coal Co., the New Superior Coal Co., and the Charles D. Robinson Coal Co. The petition sets forth that as a result of insufficient cars operating cost has increased, customers have become dissatisfied and miners are leaving to seek steadier work.

The I. C. C. on March 16 declined to support the contentions of the Weirton Steel Co., which had assailed the rates on coke from Thompson No. 1 ovens in the Connellsville region to Weirton, W. Va. The commission, in a formal opinion, held that the rates are not unreasonable.

Association Activities

Monongahela Coal Association

At a meeting held in Morgantown about the middle of March the Monongahela Coal Association re-elected C. D. Junkins as secretary for another year. John H. Jones, of Pittsburgh, was unable to be present, W. E. Watson, president of the Fairmount & Cleveland Coal Co., presiding in his stead. There were about twenty members at the meeting. Operators in attendance expressed the opinion that the lake season gave signs of being a good one in so far as mines in the Monongahela Valley were concerned.

Smokeless Coal Operators' Association Of West Virginia

Much of the time of the March meeting of the Smokeless Coal Operators' Association of West Virginia held in New York was consumed in the consideration of transportation questions. It was developed during the meeting that in what is known as general order No. 28, the Interstate Commerce Commission put the double advance upon the rail haul so that the total advance on Lake coal amounted to $1.74 and the total advance on southern Illinois coal was $1.17, a difference of 57 cents per ton against the West Virginia coals. To take care of this matter proper committees have been appointed.

Obituary

Thomas McLaughlin, for many years superintendent of the Rugby Coal Co.'s operations at Rugby, Colo., died March 6 of pneumonia at St. Luke's Hospital, Denver. While attending the Rocky Mountain Coal Mining Institute the previous week, Mr. McLaughlin contracted a cold which developed into pneumonia, quickly causing his death. Though a native of Scotland, he came to the United States when only ten years old. He served as superintendent for several of the Colorado Fuel & Iron Co. mines. For the last 10 years he occupied the position he held at his death. Mr. McLaughlin is survived by a wife, three daughters, two sons, and a brother.

Robert H. Gruschow, 58, of the Gruschow-McCabe Coal Co., wholesalers, of Chicago, died suddenly of heart trouble March 6 at his home in a Chicago suburb and was buried March 9. He was well known in Chicago coal circles for more than 20 years. He began as cashier of the Fairmount Coal Co. in 1900, was manager of the jobbing department of the old Chicago, Wilmington & Vermilion Coal Co. from 1903 to 1907, when he became vice-president of the Eureka Coal & Dock Co. In 1913 and 1914 he was president and general manager of the Eureka Company until April of 1914, when he formed a jobbing business of his own. In 1916 J. N. McCabe joined him and in 1921 the name of the concern became the Gruschow-McCabe Coal Co. It has been announced that no important change is to be made in the company. The name and business are to be continued.

Frank Colby, of Noblesville, Ind., 65, president of the Sheridan Gas, Oil & Coal Co., died recently of heart disease in Los Angeles, Cal., according to a telegram received at his home. The body was taken to his home for burial. He is survived by a daughter, Florence, and two sons, Ted and Clark.

Coming Meetings

National Safety Council will hold its twelfth annual safety convention at the Buffalo Statler Hotel, Buffalo, N. Y., Oct. 1-5. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

International First-Aid and Mine-Rescue meet will be held Aug. 27-29, at Salt Lake City, Utah.

American Institute of Electrical Engineers will hold its annual convention June 25-29, at Swampscott, Mass. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

The Virginia Coal Operators' Association will hold its annual meeting on April 21 at Norton, Va. Secretary, G. D. Kilgore, Norton, Va.

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24. Secretary-treasurer, J. G. Crawford, Chicago, Ill.

The American Mining Congress will hold its twenty-sixth annual convention in conjunction with the **National Exposition of Mines and Mining Equipment,** Sept. 24-29, at the Milwaukee Auditorium, Milwaukee, Wis. Secretary, J. F. Callbreath, Washington, D. C.

Indiana Retail Coal Merchants' Association will hold its annual meeting April 25 and 26 at the Severin Hotel, Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

International Chamber of Commerce will hold its second general meeting in Rome, Italy, March 19-26.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., Dec. 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

The Gas and Fuel Section of the American Chemical Society is arranging a second sectional meeting at the New Haven meeting of the American Chemical Society during the first week in April. The section program will consist of papers on gas and fuel chemistry and a symposium on motor fuels, held jointly with the petroleum division.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, MARCH 29, 1923 Number 13

Another Coal Crisis Passed

A NEW coal year is about to open, and with the passing of the old goes the "coal crisis" of 1922-23. In regard to bituminous coal this crisis has been a tame affair compared with some others of the recent past. Hard-coal shortage has been real, however, for production in the coal year approximated but 54,000,000 net tons—less by some 35,000,000 net tons than the mark of 89,000,000 tons in the previous year—and the demand for and consumption of hard coal is fixed largely by the more or less rigid household requirements of half of the people of this country. It was a case of 60-per cent production and therefore of 60-per cent supply. Those who would keep warm perforce must have taken substitutes to make up the 40-per cent deficit. Much criticism and complaint was lodged with the hard-coal industry, which is to say with the whole coal industry, on this account. People are averse to change and especially a forced change. Nor do they always seek and find the real cause of some of their difficulties, as for instance the relation of the strike of hard-coal miners last year to their coal shortage of this past winter.

An evidence of the coal crisis was the springing up of the state fuel administrations, and just so the closing of their offices is evidence of the passing of the trouble. After April there hardly will be a single official to look after the coal troubles of the people, for there will be no coal troubles. But there is danger of a multiplicity of coal investigations and commissions. Legislatures in the Eastern states are deluged with bills of that sort. Efforts are being made locally to have such measures held in abeyance pending the outcome of the U. S. Coal Commission's findings. It will be noted that these aftermaths of the coal shortage are confined to the hard-coal burning territory.

Altogether, with no one wanting coal that he can't get day before yesterday and with Congress home until December, it appears that the summer will be quiet, with nothing for the coal men to do but fill out questionnaires for the Coal Commission.

Come and Hear George and Henry

NO more fortunate subject than that of the solution of the coal problem by "economic rather than legislative means" could have been selected for the national resources group of the Chamber of Commerce of the United States meeting in New York in May. We are told that two speakers—names not announced—will cover the subject, the first reviewing the work of the U. S. Coal Commission and the second presenting an analysis of the coal-mine labor situation and its effect on the cost of coal. Having put this over, there will be presented THE suggestion for "seeking an economic solution." The announcement of these plans is so cleverly done that everyone is on the *qui vive.* Rumors have it that George Cushing is to take on the first part of the program, giving a complete inside view of what the Coal Commission has been doing. It also is pretty generally conceded that Henry Ford will take on the second skit, dealing mainly with the labor situation and the cost of industrial coal.

Just who is framing the economic solution for presentation to an anxious world, NO word (the emphasis is Mr. Brooking's) is vouchsafed. Guesses are divided between Joe Frelinghuysen, Bob LaFollette, Jim Reed and John Lewis, with odds on the first named as the one who now has the most free time on his hands.

It also is reported that seats in the front of the house have been reserved for the U. S. Coal Commission and its staff, but the latest reports are that the commissioners will stay in Washington on the important job of digging up facts about coal.

The National Chamber is extending a hearty welcome to all coal men, whether they have or have not sent their questionnaires to Washington. Engraved invitations are to be sent to those who since last spring, have put themselves out of the way of going in June to Atlantic City, where the National Coal Association holds forth in annual convention this year.

Guilty or Not Guilty?

MANY acrobatics of publicity have been performed in the past by the United Mine Workers of America. Now that the official publicist of the miners' union organization has declared he never condoned the bloody acts of violence against the crimes of non-unionism and the right to work committed at Herrin, Cliftonville and Willis Branch, it would be interesting indeed to witness the union at the task of convincing the American public that it, as well as its press agent, believes in law and order.

Now that the National Coal Association, in a published statement, charges the union with condoning these horrors, the time certainly is propitious for the union to clear itself of all these "calumnies" that have been cast upon it. It would do the cause of labor unionism in the United States a great deal of good if an explanation were advanced just now to show why organized union defence has been provided for every man—whether a member of the union or not—charged with murder and inciting to murder at Herrin. There must be some laudable purpose behind such a stanch defence put up without question by the United Mine Workers. There must be some legitimate reason why union officials told the hardware-store keepers in the neighborhood of Herrin to "give the boys the guns. We'll see that you get your money," or words to that effect, as has been testified under oath. There must be some reason why the United Mine Workers made every effort to prevent prosecution at Herrin, even to a drive against the special appropriation by the Illinois Legislature for the carrying on of the case

against scores of men indicted for murder last winter.

Above all, there must be some good reason why the union has never exercised its righteous power in the punishment of any union man guilty of various non-union murders.

In a large section of the public mind the United Mine Workers stand convicted of condoning murder and of striving to shackle the law-enforcement machinery of this country where that machinery was crushing down on members of the union. And this conviction in the public mind has held for months. There has been no official defence offered. Has this silence been maintained merely pending a formal charge of some sort? The charge has now been made in the court of public opinion by the National Coal Association. What is the plea of the defendant—guilty or not guilty?

Consolidation and Clinchfield

ANNUAL reports of two coal companies were published last week. They are interesting principally because of the contrast offered in the amount and kind of information conveyed to the shareholders for whose benefit they presumably were written.

The annual report of the Consolidation Coal Co. for the year 1922 is a statistical summary of the financial operations and position of the company—the history of the year as seen through the eyes of the auditors. The president, C. W. Watson, who signs the report, does not offer even the usual remarks as to whether or not, and why, the year had been a successful one for the company. Save for a fine-print footnote attached to one of the tables following the signed report, there is no reference to the coal strike. Production, it appears, was the lowest since 1901, or in twenty-one years.

Whether the year's operations were profitable must be inferred from the financial data presented. Earnings from operations are recorded as $22,464,911.76; operating expenses, insurance, royalties, taxes exclusive of federal income tax, depreciation, and depletion at cost as $19,365,303.80, and net earnings from operations as $3,099,607.96. Against these figures appears a production "mined by the company" of 5,694,256 net tons, from which it can be calculated that realization averaged $3.94, cost $3.40 and net income (for dividends and interest) 54c. per net ton. Adding to net income from operations, profits from other activities of the company and deducting interest, it appears that net earnings before deducting federal income tax were $2,733,445.66, or 48c. per ton, or about 45c. per net ton over and above all outgo, including federal taxes.

These and other calculations may be made from the financial data presented, but there is nothing to tell the stockholders what the management thinks of 1922, the strike, car shortage or prices. It is disclosed that certain moneys were used in the acquisition of the Rivesville and Stafford mines of the Monongahela Power & Railway Co., the minority stock interest of the North Western Fuel Co., and the properties of the Carter Coal Co. Nothing is vouchsafed the shareholder, however, as to the significance of these purchases. The report is a cold-blooded financial statement wherein accountants auditing the books chronicle the stewardship of dollars and cents. The president does not even "take pleasure in expressing appreciation to the officers and employees for loyal and efficient service," to quote Judge Gary in his recent report to the stockholders of the Steel Corporation.

Stockholders of the Clinchfield Coal Corporation are differently informed with respect to the operations of their company. The president, C. E. Bockus, in his report for 1922 briefly but clearly and interestingly sets forth the chronicle of 1922. His report is mainly text, with views of the new camp of the corporation at Clinchco, and a diagram showing monthly variations in output, costs and sales realization. Causes of variation in production are discussed, the effects of the strike in the union fields—the Clinchfield is a non-union operation and "no time whatever was lost from any troubles with employees"—on rate of production and on costs are described. Distribution, treatment of contract customers, wages, average costs and prices are all covered. The impression on reading this report is that an effort has been made to tell the whole story and that if anything has been overlooked, the information may be had on application.

Mr. Bockus evidently appreciates the value of presenting information in the three ways—namely, by text, diagram or picture and statistical table—certain that one method at least will appeal to every reader. Incidentally Clinchfield averaged net earnings of 38c. per net ton before deduction of interest, dividends and federal income taxes, as against 54c. for the Consolidation.

Flotation in an Oil Foam

WHEN particles become small their surfaces are unduly large compared with their weight and in consequence their relations to any surrounding medium become of more importance than their specific gravities. A fine unwetted heavy dust will float on the surface of the water, and a colloid will sink only with great difficulty, even when wetted.

For this reason the flotation experts believe that coal, which so freely floats on an oily froth, can be best separated by that method. Of course, a particle of coal with a thin ashy exterior may tend to sink, which we might not want, and one with an ashy heart may float satisfactorily, despite the fact that it should be rejected, but these conditions are so infrequent that the difficulty rarely would be encountered.

One great advantage claimed for the flotation method is that with it fusain, or mineral charcoal, will be rejected if the right flotation medium is used. Fusain is regarded as the substance which interferes with coking. It is said that many non-coking coals would coke if their fusain were removed and that coals that refused to coke have made good metallurgical coke when this deleterious material was eliminated.

Little claim is being made for the removal of pyrite by flotation. It is found that the pyritic content of coal can be slightly lowered thereby, but the reduction is not large. Perhaps a combination of flotation and gravity methods may solve the difficulty, the gravimetric methods removing the sulphur and the flotation eliminating the ash after the coal has been crushed.

Another feature with flotation is that oil covers the mineral substance with a thin film. As a result any water mixed with the coal can be eliminated in the briquetting press, and coal, it is asserted, can be briquetted with less binder and with binders of a less expensive character than is possible where the flotation method does not precede briquetting.

Maintenance and Repair Methods in the Shops of the Consolidation Coal Co. at Jenkins, Ky.

How Split Gears Are Welded Solid—Locomotive Tires Rebuilt by Welding at Cost About Half That of New Tire—Restoring Rail Benders—Protecting Edges of Concrete Floor in Motor Barns

By Alphonse F. Brosky*
Pittsburgh, Pa.

EXTENDING along the main street at the lower end of the town of Jenkins are the shop buildings in which are made practically all repairs for the mines at Jenkins and McRoberts and some for the Millers Creek Branch of the Consolidation Coal Co. at Van Lear, Ky. As is customary with most isolated coal-mining operations, the shops are equipped to make almost any kind of repair, and consequently the department includes a carpenter shop, a blacksmith shop, a plumbing shop, a welding shop, an electrical repair shop and a brass foundry.

In the carpenter, or wood-working, shop finished lumber is manufactured for houses from rough lumber obtained in part from the sawmills of the company and in part from the open market. Not only is the wood for building prepared and cut to proper sizes in this shop but here also are made brake shoes for mine cars, tamping rods, trolley poles, stakes and plugs for the engineering department, motor bumpers and other miscellaneous materials. Occasionally in slack times small pieces of furniture are made so as to keep the working force intact.

Wood-Working Machinery Unusually Complete

The equipment in the wood-working shop includes a tenon-making machine, three planers, an auger press, two lathes for turning wood, one band saw and two disk saws. An interior view of the carpenter shop with its machine equipment is shown in Fig. 1.

In the blacksmith shop, adjoining, several men are employed rebuilding wagons and repairing their wheels.

Note—The headpiece of this article shows the shop buildings of the Consolidated Coal Co., at Jenkins, Ky., in which is repaired the machinery from fourteen mines in and about Jenkins and in which special work is done for the mines at Van Lear, in the same state.

*Assistant editor, *Coal Age*.

An adjacent building houses the brass foundry and the welding shop. In the foundry, castings of all descriptions are poured. The jobs include the making of journal brasses for locomotives, bearings, bushings, adjusting nuts, quill bushings and other pieces which might be needed in an emergency. As an example of the variety of work done in these shops it may be noted that when the management found that the filter pumps, which carry the water from the lime tank to the clarifying tanks in the filtration plants, required frequent repair it decided to make these pumps and parts in the company's own shops.

Split Gears Waste Time and Come to Grief

Disregarding the customary jobs of the welding shop the process of welding split gears for mine locomotives is worthy of particular note. Though split gears have been welded by companies for years, the method of procedure of the Consolidation Coal Co. gives so strong and true a gear that a description of the work should be of value.

It has been calculated that at a mine of 2,000 tons daily capacity having locomotives equipped with split gears the machine boss or his helper spends 6 to 8 hours each week in tightening loose gears. Aside from the saving of this time, split gears should be made solid because a gear which is loose on the axle will spoil the retaining pin and slots and ruin the axle.

It is not difficult to weld a split gear so that it will have the necessary strength but it is not easy to do it and at the same time maintain the hub, or bore, so that it will fit the shaft correctly and the teeth so that they will be truly centered during the welding and after the piece has cooled.

The edges of the split gear are beveled with an

acetylene welder, as illustrated in Fig. 2, thus providing a larger bonding surface. Sometimes the bore of the hub is cut out in a V-shape at the split; especially is this done when stock must be added to the bore in any event to take up the play caused by wear. Then the exposed surfaces are ground to insure a good bond between the metal of the gear and the filler. A mandril of a diameter exactly that of the axle of the locomotive is fitted in the hub of the split gear, and the bolts are tightened up so as to assure that the gear will not be of variable diameter, as there always is some clearance between the two halves which must be adjusted by holding open the hub of the split gear. Otherwise the bonding metal, applied with an electric-resistance welder, would contract and draw the two halves together. Then the gear would not fit over the axle nor would it mesh properly with the drive pinion. Sometimes also the nuts and projecting bolt ends are fused together by means of the torch.

The gear is forced on the axle with a pressure of 50 tons. If the bore is worn and has to be built up, the time required to complete the job is about 4½ hours. If no stock is added to the bore, the work is accomplished in 2½ hours. Of forty-eight gears made solid in the manner described, only two have been known to fail.

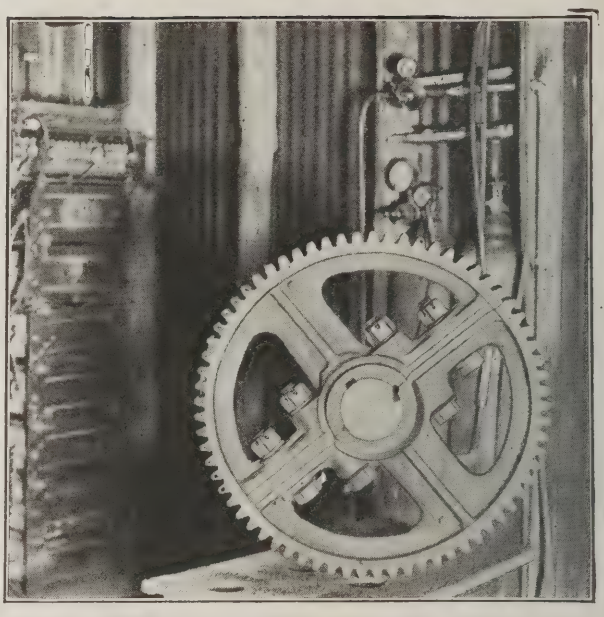

FIG. 2—WELDING SPLIT GEAR OF LOCOMOTIVE

The edges of the surfaces where the two halves come together are beveled with an acetylene welder, and the bore of the hub may be beveled also at the split. The edges are then ground. The wheel is fitted on a mandril, and the bolts are tightened so as to make the gear of the exact diameter designed. Then the wheel is welded by electricity, which makes a true gear with all teeth of equal pitch.

Machine Shop Builds Up Worn Locomotive Tires

Several interesting repair jobs are done in the machine shop, most important of which is the building up of worn locomotive tires, using a motor-generator welding apparatus. The general arrangement of the revolving holder for the tire being repaired is shown in Fig. 3. The wheel holder consists of a horse which is pierced by a threaded shaft on one end of which is a spoke cross which holds the tire. The tire is made to encircle the spokes and is then held by two wooden wedges.

In applying the iron to the tread of the tire one complete revolution of the wheel moves it toward or away from the operative through a distance equal to the lead of the thread, which also is its pitch, as the thread is single. Thus the electrode is relatively the same distance in front of him whether he is applying the metal at the flange or on the opposite edge of the groove in the tire. This gives him greater support for his hands and a more facile control of the molten metal which is being threaded around the tread, because he moves the electrode across the tire in practically the same path at all times.

He revolves the wheel slowly by pressing his foot against the spokes. The thickness of iron applied to the tire depends upon the wear to which the tire was subjected. A considerable saving in the maintenance of locomotives is effected in this manner.

When the tires of railroad locomotives were first

FIG. 1

Carpenter Shop

Modern woodworking machinery eliminates in this shop much of the handwork otherwise necessary in jobs of all kinds, especially cabinet work. The auger press in the foreground and center bespeaks how modernly this shop is equipped. Brake shoes are made for mine cars, tamping poles for loading auger holes, trolley poles and bumpers for locomotives and stakes and plugs for the engineers. In slack times even pieces of furniture are manufactured. The shop contains, in addition to the auger press, a tenoning machine, three planers, two wood-turning lathes, a band saw and two disk saws.

built up by electric welding, several of the carriers put the tires back in service without surfacing the tread. The Interstate Commerce Commission ruled that all tires which are rebuilt must be ground. Some men in the coal industry are of the opinion that tires which are rebuilt by electric welding may be put back into service without surfacing the tread. This is a mistaken belief, at least the Consolidation Coal Co. thinks so. Accordingly, behind the welding operative in Fig. 3 may be seen a 76-in. wheel lathe that will be equipped with a small grinding wheel shafted to a specially improvised turnstock. This will be used to true the tires after their treads have been welded.

New tires give about fifteen months' service and form a $\frac{3}{8}$-in. groove before they are repaired. If the false flange is turned in a lathe, the Consolidation Coal Co. has discovered, the tire will give further satisfactory service but for no longer than four months. Then the tire must be discarded. On the other hand, a built-up tire can be used daily for ten months without needing rebuilding, and there is no limit to the number of times this can be done.

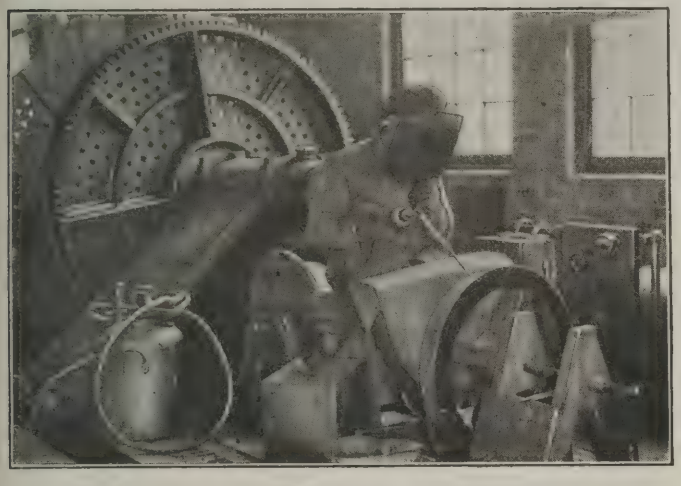

FIG. 3—BUILDING UP WORN LOCOMOTIVE TIRE

Tires at the Jenkins mines, when worn, are built up by electric welding. The illustration shows the way in which the point at which the welding is being done is kept at a uniform and convenient distance from the welder. The large wheel lathe behind the operative will be used to grind the tire after it is built up.

Another interesting repair job is that of overhauling worn rail benders. Due to the enormous pressure which necessarily is placed upon the threads of a 40-lb. rail bender, the nut wears down until it will no longer hold the screw. Then the bender either must be repaired or else thrown on the scrap pile. The screw is not worn out at the same time as the nut, because the former has many more threads than the latter and thus is able to withstand the wear.

One of the methods commonly employed in repairing a worn rail bender consisted in cutting off the claws from the shoulders at *A* and *B* (see Fig. 4), plugging the hole, boring the plug and cutting a thread in it. Afterward the claws were welded onto the shoulders. This method was abandoned because the cost of the repair was almost equal to that of a new bender.

The method used by this company at Jenkins is simple and low in cost, yet the rail bender is made "like new." Referring to Fig. 4, one may see that all that is necessary is to ream out the nut, insert a machine-cut steel tube that is threaded on the inside and has a collar on one end and weld the collar and the protruding end to the body of the rail bender.

Thus far twenty 40-lb. mine rail benders have been remade as specified and all these are still giving satisfactory service after a period of time long enough to make a fair test of the quality and suitability of the work, and quite a saving has been realized.

Periodical Repair a Guarantee of Service

How frequently it happens that companies are entirely pleased with the performance of their underground equipment until it ceases to be new! Then they complain that the machine does not "stand up"? Of course it does not if it receives little or no care. Observations over a period of a few years have brought us to a realization that daily inspections (during which times minor repairs are made if necessary) and periodical overhauling are needed to obtain maximum efficiency and real economy in operation.

In an article dealing with the mines of the Consolidation Coal Co. near Jenkins the methods of maintenance of the arcwall cutting machine will be explained. The moving parts of all mining machines will wear, some parts in a short time and others after a longer period of service. When the parts are thus worn the machine no longer functions correctly. The coal cutters used in the mines of this company are taken one at a time to the shops, where they are torn apart from end to end, so that no two fitting parts are left engaged. This gives the machinist an opportunity to clean the parts thoroughly and at the same time inspect each part for wear. Worn parts are replaced, or if the piece is large it is built up with a welding outfit and then machined. An arcwall coal cutter thus torn down and being repaired is shown in Fig. 5.

Track Laying Usually Faulty in Motor Barns

A great mistake has been made throughout the coal fields in the laying of track or, if you will, in the placing of the concrete floor in motor barns. Rails are laid on cross ties as usual, and concrete is then poured flush with their treads, a slot being left, however, on either side of the rail. This construction is objectionable, for sharp corners are left at the edges of the slots. These soon chip off and break as shown in Fig. 6.

The Elkhorn division of this company has two solutions for the problem presented by this breakage. In its No. 201 mine at Burdine the rails are spiked to 8x8-in. oak sills as shown in Fig. 7. It will be noted that the sills rest in a right-angle cutout so as to lie

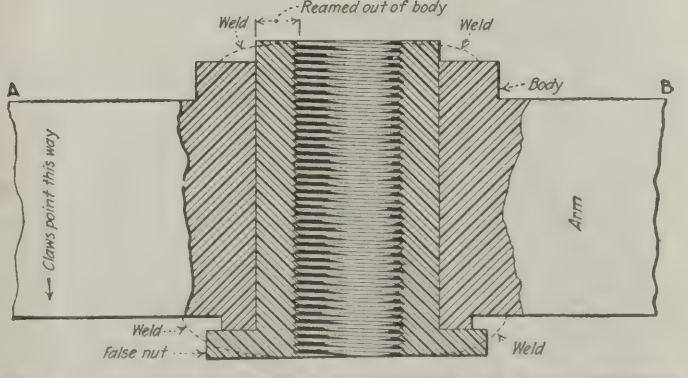

FIG. 4—METHOD OF RENEWING SCREW OF RAIL BENDER

The screw threads on rail benders wear out rapidly in working on heavy rail and become inoperative. The hole can be plugged, the plug bored and the hole threaded, but to do this the claws must be cut off, and when the job is done they must be replaced by welding. To avoid this the nut is reamed out, a machine-cut steel tube is inserted and welded into place, greatly reducing the time needed.

FIG. 5

Overhauling Arcwall Cutter

Too many operators seem to imagine that their machine cutters will go on operating without any attention other than the rewinding of an armature or the replacing of a gear now and again. They need, however, much more considerate attention. The Consolidation Coal Co., at Jenkins, tears its machines down completely and reassembles them, replacing worn parts and building up large pieces, such as the bedplate, where badly worn.

flush with the concrete floor and the walls of the pit. The rails project above the floor. At points away from the pit the sills are cross-braced by wood ties.

The second solution is perhaps the better of the two, as the method of construction is quite simple. At the same time it accomplishes the purpose of protecting the corners of the concrete without elevating the track. Track and concrete flooring thus laid is illustrated in Fig. 8, which is an interior view of the motor barn at No. 214 mine. The work is done as follows: The tracks are laid in the barn on wood ties as on surface and underground tramroads, except that greater care must be taken to put the surfaces of all tracks in the plane of the floor. Oak stringers are spiked to the ties on either side of the rails, leaving approximately a 3-in. slot. The stringers should be flush with the tops of the rails; then the concrete may be poured and readily surfaced, as the stringers act as forms to keep the concrete away from the track. They also aid the men in finishing the floor.

FIG. 6—HOW NOT TO LAY CONCRETE FLOORS IN MOTOR BARN

The floors in most motor barns have broken along the rails just as this has. It shows how with almost perfect tracks locomotives wander around on the rails. To avoid this breakage the Consolidation Coal Co. has made the provisions described in this article.

Figs. 8 and 9 indicate the types of motor barn which this division of the Consolidation Coal Co. believes are best suited to its needs. Though the barn is not an expensive structure, it meets the conditions of these Kentucky mines, for the winter seasons bring more rain than cold. Nor are the barns uncomfortable in the summer, as a pleasant current of air blows through them when the doors and windows are open.

One sometimes wonders why in mild climates motor barns are so frequently built of brick. Where winters are severe a brick structure certainly is necessary to protect the men from the cold. But it appears that brick is preferred also because it is permanent. That would seem a good reason but if a corrugated sheet-iron barn will last half as long as a mine, would it not be better to erect the less expensive structure, when its cost is not more than half that of a brick barn of similar proportions?

With a concrete flooring properly elevated from the ground and drainage facilities provided around the outside there is no reason why the structure of sheet iron should not stand for many years, providing it is given the proper attention, which includes periodical painting of the metal siding and roofing. At the halfway mark in the life of a mine circumstances may warrant a change either in the design or location of the barn. The

old building may then be used for storage or for some similar purpose and a new one erected. The cost of both is no more than the cost of one made of brick, of concrete or of hollow tile plastered with cement mortar.

Sometimes doors are placed on both ends of the barn, and a run-around track allows motors to enter from either end, but the location of the barn in Fig. 9 is such as to prohibit the use of two entrances. Too often motor barns are not kept in an orderly condition but those shown in the two illustrations show the benefit of the stringent rules laid down by the management in this regard.

The barn shown in Fig. 8 will house three cutting machines and seventeen locomotives. Upon close inspection of the illustration one will notice several resistance grids suspended above the right-hand track. These are especially useful to provide a slow charging rate for one or two battery locomotives that may have

FIG. 7—LOCOMOTIVE PIT WITH UNBROKEN CONCRETE EDGES

Careful inspection of the illustration will show that the track rests on wood sills. These sills, which are of oak, measure 8x8 in. and the concrete is run up to them. The rails, however, project above the floor, which is not a desirable arrangement though less objectionable at the pit. The sills are braced by wood ties wherever the absence of the pit makes this practicable.

been in hard service on a slack day. It is not economical to keep a man on night duty when only a few locomotives have to be charged, and consequently it is well to provide means whereby batteries may be charged at such a slow rate that no supervision will be needed.

Fig. 6 shows a 6-ton General Electric cable-reel gathering locomotive which has been equipped with a new type of reel manufactured by the maker of the locomotive and now being tried at the mines of the Elkhorn division. The reel is driven through a reduction pinion and ring gear. The positive drive provides a satisfactory means of taking up the cable. The old type disk-driven reel causes trouble because it is likely to slip, in which case the cable is not picked up as fast as the locomotive progresses. Because the reel is constructed of steel the electrician at this mine has grounded the reel frame and shaft to the base of the locomotive. Hence if the copper of the cable becomes exposed and comes in contact with the metal of the reel, as it sometimes does, the men will be guarded against shock.

The trolley gate shown in Fig. 10 is located on a

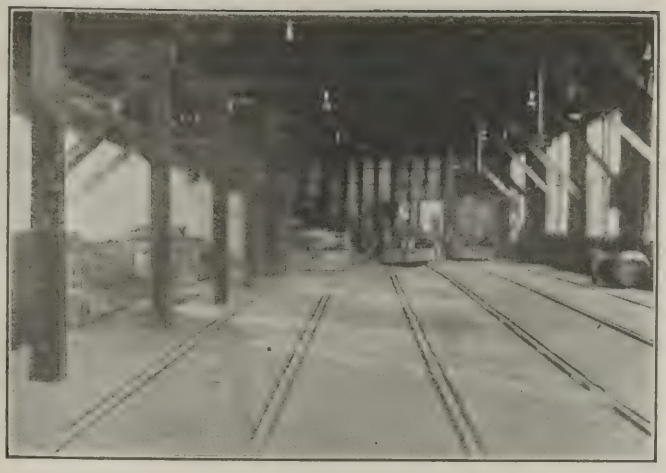

FIG. 8—LOCOMOTIVE BARN WITH WELL-LAID FLOOR

The concrete lies flush with the top of the track and its corners are protected by oak stringers on both sides of the rails, providing a slot approximately 3 in. wide. The stringers are of such a depth that their tops will be level with the running surface of the rails.

tramway connecting No. 204 and No. 207 mines, at a point where it crosses a public road at Dunham as part of a continuous track from Jenkins to McRoberts. During the war, when coal was sometimes hauled on the public road where it crossed the track, a gate keeper was stationed here to prevent accidents.

Such a trolley gate should find application at many mines. Wagon roads, both public and private, often cross the tramroads of mines and the loads on trucks and wagons using the road generally project above the level of the trolley wire. With a trolley gate similar to the one shown the trolley wire is almost continuous, yet the road which crosses the tramroad is not blocked against road traffic.

The manner in which the gate is constructed is quite obvious. Two converging angles are tied together by strap steel and form the bridge. Five angle brackets carry a trolley guard of wood and trolley clamps, to which is attached a bridge wire which merely guides the wheel of the harp across the gate and is not meant to close the circuit. The circuit is diverted to a line carried up and across the poles as shown. Though the wire on the bridge is not part of the regular circuit current can be taken from it by making a connection between it and the ground. Consequently it is necessary to provide a trolley guard.

Mechanical men about the mines have not as yet come to a conclusion regarding the relative merits of

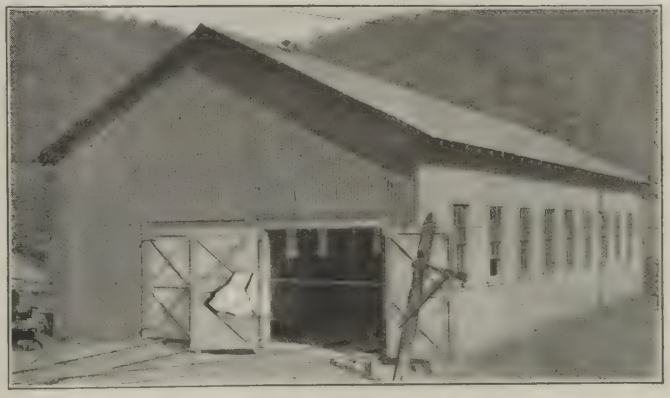

FIG. 9—CORRUGATED SHEET-IRON LOCOMOTIVE BARN

A barn of this type serves every purpose where the winters are not severe and costs about half that of a brick, concrete or stuccoed-tile barn.

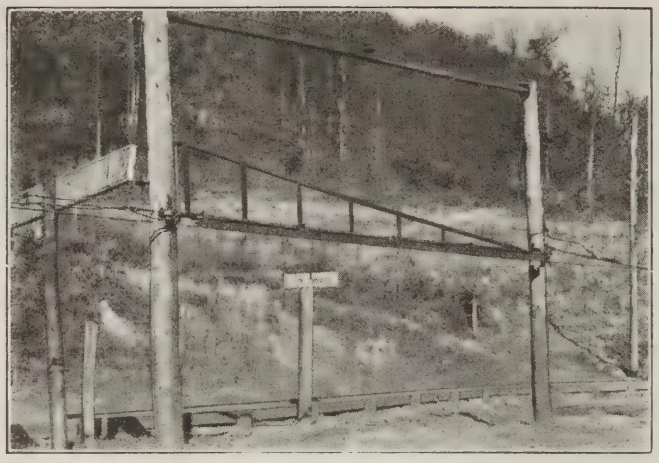

FIG. 10—TROLLEY GATE OVER PUBLIC ROAD

This is a device for swinging the trolley line over places where traffic has to cross the tramroad. The opening of the gate does not break the circuit for that passes at all times through a conductor placed at a much higher elevation. However, when the gate is closed the locomotive gets power throughout its travel and does not have to depend on the momentum of the trip as it does where there is no gate but merely a gap in the trolley line. Besides the gate guides the trolley wheel so that it picks up the wire on the far side of the road.

direct-connected and gear-driven centrifugal pumps as against those for which a belt drive is provided. Many arguments may be made in favor of each type of drive, but the pump operatives of this division of the Consolidation Coal Co. like the belt drive the better because it is more quiet and because the pump may be reached more readily when repairs are to be made. Good belting will last many years even when used in a small pump station hollowed out of the coal and rock. What little take-up is required is adjusted easily. In such a place ordinary steel gears are prone to rust, and then they do not function efficiently. In Fig. 11 is a centrifugal pump of 250-gallons capacity which is belt-driven by a 25-hp. direct-current motor. In rainy weather this pump runs continuously throughout the 24 hours of the day and sometimes for days at a time. About 90 per cent of the pumps are, however, direct-connected.

Slate is disposed of at most of the mines of the Elkhorn division by an endless-rope aërial tramway which carries two 1-ton drop-bottom steel buckets from which the slate is discharged automatically by the tripping of the gate. Two 1½-in. round track steel cables are used for suspending the buckets and a ⅝-in. stranded steel cable which is endless is the motive agent. The endless rope is moved by a horizontal finger sheave which is driven through a pinion and ring gear by a 25-hp. induction motor. The sheave at the upper end of the dump is counterweighted to keep the rope taut.

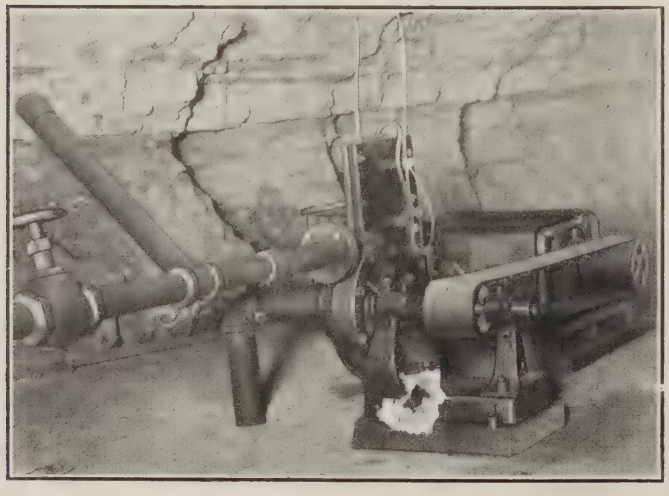

FIG. 11—BELT-DRIVEN CENTRIFUGAL MINE PUMP

Gears underground are likely to rust whereas a belt thrives in these mines, as the air is damp and the temperature never hot. This installation is at Mine No. 201, Burdine, Ky.

Slate from the mine is deposited in a 100-ton bin by a kickback dump and is fed into the buckets through the manipulation of a control lever at the bin which operates a counterweighted sliding gate. The slate is carried from the lower bin over two or more towers to the top of a hill. It is further disposed of by one of three methods: It may be dumped from the rope; it may be dumped into a bin on the hill, in which case it may be either distributed by an electric larry of about 8-ton capacity having a revolving body which discharges to either side by gravity over an inclined floor, or it may be slid over the slate bank by means of sheet-iron chutes, as at No. 206 mine, where the slope is approximately 50 deg.

FIG. 12—AERIAL TRAMWAY FOR DUMPING WASTE ROCK

Two buckets carry the slate from a 100-ton bin up the mountain side. The slate can be dropped on the way or dumped into a bin near the top of the hill. In the latter case it is handled either by an 8-ton larry which discharges entirely by gravity or it is dumped from the bin and slides down the slate bank with the aid of sheet-iron chutes.

The general arrangement of the aërial tramway at the joint tipple of No. 207 and No. 208 mines is illustrated in Fig. 12. Here the slate is deposited in a bin at the top and is removed from it for disposal by means of an electric larry. The slate bank in the illustration has just been started. Any one of the three methods of disposing of slate by means of an aërial tramway requires the services of two men.

COMMENTING ON THE VERDICT in the miners' case an Eastern editor says that "Herrin is a sick community." Maybe that's why they write it Herrin, Ill.—*Nashville Southern Lumberman.*

ALL THAT GLISTENS IS NOT GOLD. Neither are all the black lumps in the bin combustible.—*Boston Transcript.*

Outbursts of Gas and Coal at Cassidy, B. C.

As Much as 1,500 Tons of Coal and Over 1,200,000 Cu. Ft. of Gas Disengaged by a Single Blowout—Mine Has Had 160 Outbursts —Boreholes of No Avail—Wide Places Prevent Recurrence

By J. B. Touhey*
Cassidy, B. C.

THE Cassidy slope is working in what is know as the Douglas coal bed. In order to provide liberally for its ventilation, two intake and two return airways are provided. The main slope or haulage road is driven 12 ft. wide clear of the timbers, the height above the rail being nowhere less than 6 ft. The second intake is used as a manway or traveling road and is driven 9 ft. wide inside the timbers and has a minimum height of 6 ft.

The return airways, of which there are two, one on each side of the intakes, are separated therefrom by a 150-ft. pillar of solid coal, except every 1,000 ft., where the main levels cross them from the main haulage roads. Each district is ventilated by a separate split from the main current, and overcasts conduct the return air over these main levels (Fig. 1).

A splendidly installed Sirocco fan with a capacity rated at 150,000 cu.ft. per minute with a 6-in. water gage is used as an exhaust. It is so located as to make intakes of the haulage road and manway. The volume of air specified is being provided already, but the water gage as yet has reached only 4½ in., principally because of the large size of the airways traversed.

Tests with the Burrell gas detector, which has been found to check up fairly accurately with laboratory tests under normal conditions, show from 0.2 to 0.7 per cent methane in the returns. The slope and manway are driven on the full pitch of the seam, which averages 18 deg., and have been extended about 5,600 ft.

The main levels in No. 1 are driven about every 1,000 ft., and slopes and inclines are driven off these levels from the intermediate panel haulage roads. From these entries level rooms are driven. The output is about 1,000 tons per day. No horses or mules are used underground. The thickness of the coal varies from 1 ft. to 30 ft., the undulations being mostly in the floor and in the middle of the seam, the condition of the roof being fair.

The inclines and slopes are driven 10 ft. wide, and the rooms turned off them have a width of 15 ft. Two certified miners are allowed to each room, no miner's helpers being employed. Permissible electric cap lamps are used for illumination to the exclusion of all other lights. For testing purposes Wolf safety lamps are employed, but they are used solely by firebosses and the management.

The Douglas seam, which, as already stated, is developed at this mine, is the uppermost of the three that are being worked in this district. The Newcastle seam, the existence of which is problematical at this mine, is separated from the Douglas bed by about 175 to 200 ft. of strata which consist chiefly of sandy shale and sandstone in massive formation.

The seam has been subjected to a great geological thrust from the south which has caused the floor and coal to buckle, but the roof apparently has resisted the thrust, hence its fairly normal condition. In consequence of the buckling and sliding of the seam the upper portion of the bed is slickensided and the bedding planes, or stratifications, have been destroyed. The slip planes in the coal sometimes start at right angles to the floor, curving upward, and as these are mostly slickensided it is probable that the slip planes are coated with a clay that is impervious to gas.

In some areas the coal has been thrust or squeezed into irregular and thick masses, these thick coal areas being surrounded by others where the coal has been rendered thin by rolls or even squeezed out altogether. These barriers vary from 100 ft. or so square to several

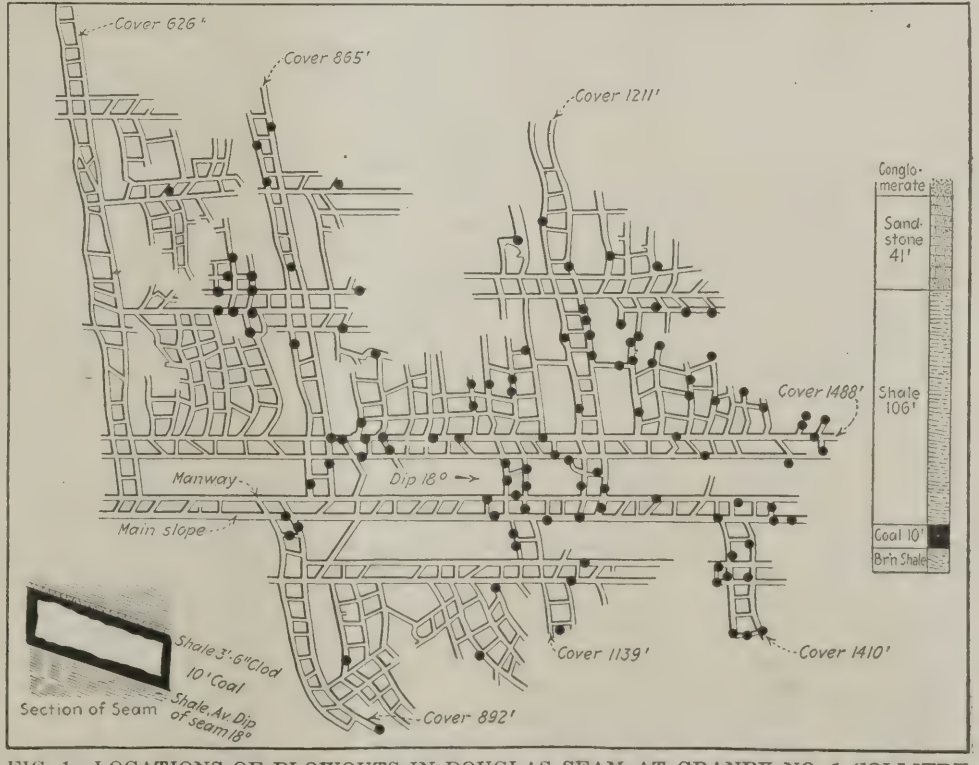

FIG. 1—LOCATIONS OF BLOWOUTS IN DOUGLAS SEAM AT GRANBY NO. 1 COLLIERY

About 160 blowouts have occurred in this mine. It will be seen that they frequently occurred at depths of less than 800 ft. Every evidence points to something other than the present weight of cover as the cause of these blowouts. As in Belgium, the blowouts neither liberate much methane nor relieve the seam of pressure. This map shows only the inner part of the mine.

*Mine manager, Granby Consolidated Mining, Smelting & Power Co.

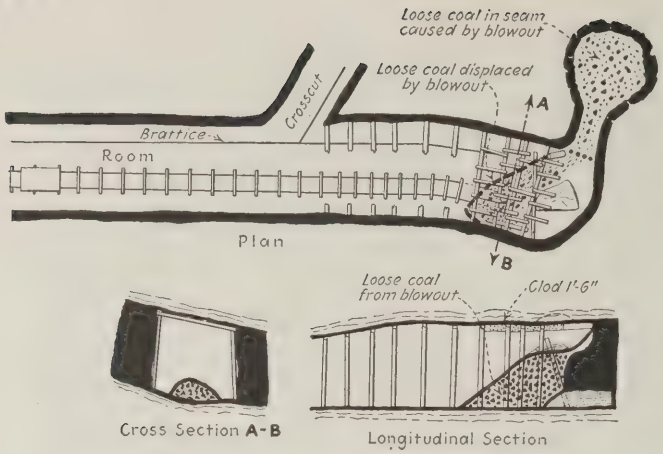

FIG. 2—BLOWOUT IN THE FACE OF A ROOM

This is one of the smaller outbursts. Note the bottle-shaped mouth of the cavity it has formed in the seam. What seems so extraordinary is the fact that areas so different from other areas are to be found in the coal seam. It is a difficult speculation to imagine how they may have been formed.

acres in extent. Careful study has been made to ascertain the relations, if any, between the outbursts of gas and these rolly barriers, but no relationship has been found. The outbursts occur both in thick and thin coal, the geological aspect of the squeezing not seeming to have any effect on the gas pockets.

The outbursts first made their appearance in January, 1921, and from that date until the present about 160 outbursts have occurred, each displacing from 50 to 1,500 tons of coal. The depth of cover under which the first outbursts occurred was about 350 ft., whereas at our lowest present development the cover is about 1,500 ft.

All Blowouts Occur At or Near Coal Face

The accompanying plan (Fig. 1) shows the positions of ninety of the largest outbursts. In studying these it is necessary to remember that, with two exceptions, the outbursts occurred at what was then the working face. These two exceptional blowouts happened after the face had advanced about 40 ft. All the outbursts to date have given premonitory sounds of warning, the coal breaking and cracking at the face. At times this warning will continue for two or three days intermittently; at other times the warning is of only a few minutes' duration. Two forces oppose one another in every outburst: the gas pressure, which exerts a bursting force on the coal, and the strength of the coal resisting movement. As the resistance is reduced by removing the coal, a time comes when the strength of the coal is slightly the lesser force of the two, and from that moment the coal moves. The motion may be only slight and of short duration, as was the case in July, 1922, when two fatal accidents occurred in which men working at the face were buried by coal from two blowouts. The surviving miners in each case testified that a slight warning had been given, but not sufficient to afford them time to get away from the flying coal.

In November, 1921, it was decided that blasting should be dispensed with in the blowout area, but as the coal was fairly soft that revision in practice did not materially reduce the earnings of the miners. After the two fatal accidents mentioned above it was decided to discontinue one of the shifts and put three boreholes at least 20 ft. deep and 2 in. in diameter in every place in the affected area, these holes to be kept 20 ft. ahead of the face. This method has now been employed over three months, but the outbursts are still happening, and up to the present time no pressure has manifested itself in any of the exploratory holes.

The number of outbursts decreased during the month of December owing to a large reduction in the number of places being worked in that area. On the other hand we decided to widen out the rooms to 35 ft. and it is gratifying to know that during the three months in which experiments have been made in this system we have not had a single blowout in a double room, which also accounts for the reduced number of outbursts in December. Our blowouts are unique, as sometimes a second blowout will occur within 20 to 25 ft. from the point where the first one occurred.

The gas would seem to be pent up in in a large number of small pockets under enormous pressure. The liberation of the gas is not instantaneous although the volume given off is extremely large. An outburst on March 20, 1922, displaced 1,000 tons of coal and emitted approximately 1,200,000 cu.ft. of methane in 10 hours. The gas continued to flow in steadily lowering quantity for a further 36 hours.

Much Gas from Blowout; None from Borehole

It is true that sometimes a little gas issues from the mouth of some of the exploratory holes, but at no pressure. Had the gas emitted by the blowout recorded in the first ten hours passed off from three exploratory holes of 2 in. diameter tapped in the seam and had the gas come out of each one of these at 50 lb. pressure per square inch, it would have taken more than five months to drain off the gas that was emitted, but, as previously stated, we have not yet tapped any pressure of gas, and yet the blowouts are still occurring wherever the places driven in the coal are narrow.

A blowout can sometimes be heard 500 ft. away through the solid coal. The sound in most cases resembles the noise made by a rapid-fire or machine gun, and sometimes it lasts three or four minutes. The districts on each air split being small, the miners are enabled to get to fresh air quickly, and they are daily instructed by the officials not to place any confidence in the boreholes but to withdraw to fresh air at the first sign of warning.

As previously stated, the outbursts at this mine are unlike any of the blowouts that hitherto have come to my knowledge. At Fernie, B. C., for instance, the enormous volume and weight of gas constantly escaping from the advancing coal face may cause a shrinkage in the thickness of the coal, which in turn may bring about roof readjustments causing undue pressure and consequent larger outflows or outbursts. Exploratory holes may be of value in such a case.

In the mine under consideration no great volume of gas flows from the coal under ordinary conditions, and the probability of roof readjustments due to disengagement of gas may be safely dismissed. These gas pockets have been formed by the squeezing and crumbling of the coal, the grinding and crushing of which has evolved the gases which are then pent up behind an impervious coal stratum with clay slips. Another peculiarity is the fact that no matter how large the displacement of coal from these outbursts no cavity ever is found large enough to have held such a large quality of coal as has been forced into the workings.

The two following blowouts are typical of these occurrences in our mines, both large and small. An outburst

occurred at 9:30 p.m., Oct. 17, 1922, in No. 7 Level. This level was 14 ft. wide from rib to rib and 13½ ft. high. Timbers were set at 4-ft. centers and 12 ft. between the notches. The face was 55 ft. ahead of the last crosscut. Three exploratory holes had been drilled in advance of the face, the center hole 24 ft. deep and the flank holes 20 ft. deep. The fireboss, on making his inspection, could not get a trace of gas in the place, neither could he get any from the boreholes, though he tried them as late as 8 p.m.

At 9:30 p.m. the face began to be uneasy, and the miners decided to withdraw. They had left the face only 3 minutes when the outburst occurred with a heavy boom, momentarily reversing the air current, raising curtains and opening doors within a radius of 500 ft. When at last an inspection could be made, which was about 12 hours later, the entire level from the center of the crosscut, a distance of 55 ft., was completely blocked with fine coal with the exception of a space about 18 in. square along the higher side rib. Here methane was issuing at great velocity. The outburst came from the direction of the level and right rib and knocked out twelve sets of timbers. After loading out a little more than 800 tons of coal and replacing the timbers the original face was reached, and loose coal was encountered for another 15 ft., but no appreciable space could be discerned from which such a large quantity of coal could have come.

A general sample collected from this outburst screened as in Table I.

TABLE I—SIZES OF COAL EMITTED BY OUTBURST

Screen	Per Cent	Screen	Per Cent
Plus ¼ in.	0.0	Plus 80-mesh	9.3
Plus 20-mesh	13.4	Plus 100-mesh	4.8
Plus 40-mesh	26.8	Minus 100-mesh	24.3
Plus 60-mesh	21.4		

Ash content of sample, 30.18 per cent.

An outburst of gas and coal occurred in No. 1 Room, No. 6 North Incline (Fig. 3). This room was 24 ft. wide and the outburst violently displaced 1,500 tons of coal and gave off approximately 1,200,000 cu.ft. of gas in 10 hours. For the next 72 hours the gas continued to be emitted, but at the end of that time the mine was again in such condition that it could be operated. No space that could hold such a large volume of gas could be found.

In order to test the efficiency of exploratory holes a place was chosen that was giving signs of an outburst. This place on Sept. 29, 1922, had three exploratory holes 20 ft. deep. With the exception of a ¼-in. cap of gas coming from the flank hole on the right rib not a trace of methane could be found. The place was stopped and remained idle until Oct. 3, or more than 100 hours.

In the meantime eighteen additional holes, 2-in. in diameter and from 20 to 24 ft. deep, were drilled in an effort to tap the gas. With the exception of very slight gas caps at four of the holes no gas was tapped. A test with the Burrell gas detector at the highest point in the roof showed 1.4 per cent methane. The place was allowed to work on Oct. 3 and after 5 hours' work, when about 10 tons of coal had been mined, an outburst occurred which was unusually violent, displacing 250 tons of coal and knocking out nine sets of timber.

An enormous quantity of gas was liberated for the next 36 hours. On a return to the original face it was found that from 3 ft. to 6 ft. of three of the center holes were in perfect order. Other experiments with exploratory holes have given the same results. Fig. 2 shows a small outburst from the face and high-side rib.

Having witnessed a number of these outbursts and listened to the evidence given by officials and workmen, I have come to the conclusion that not only is the gas under compression but that the coal itself also is equally compressed, the coal acting as a sponge containing the gas. On liberation the coal expands with a consequent effusion of the gases.

Sometimes the loose coal, after it is loaded into the mine cars, is so impregnated with gas that a safety lamp will be extinguished if put on the car. The driving of double rooms 30 ft. to 40 ft. wide has reduced the number of outbursts. In the places where conditions were such that rooms of this width could be driven we have not had a single occurrence of this sort for the three months during which we have been driving them.

In conclusion, from my experience here I believe that

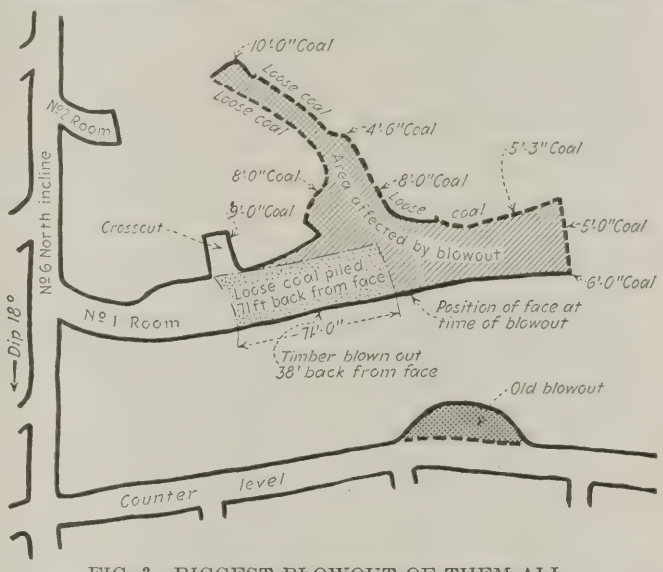

FIG. 3—BIGGEST BLOWOUT OF THEM ALL

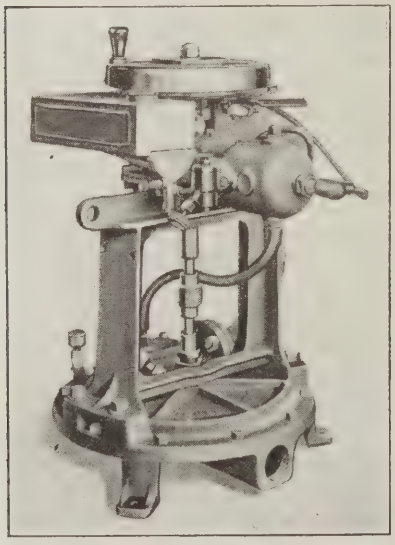
In this blowout 1,500 tons of coal was discharged into the heading from an area of weakness of a peculiar shape. Note how the thickness of the coal varies from 4 ft. 6 in. to 10 ft. and quite irregularly. More than 1,200,000 cu.ft. of methane escaped from the self-excavated area.

any mine subject to blowouts of the same nature as at Cassidy should be worked either in double rooms or longwall, where suitable, as this allows the spongy coal and gas more room to expand and the gases will gradually bleed off and prevent sudden liberation.

In places where conditions would not allow either longwall or wide double rooms I would recommend shooting the coal after it is well prepared, either firing one place at a time commencing on the return side of the faces or blasting all shots at once from the surface wherever this would not be contrary to existing mining laws, no one but shotfirers being in the mine at the time.

The great danger we have to guard against, apart from the dangerous condition of the atmosphere after a blowout, is the occurrence of outbursts with only slight warning, which might come suddenly and bury the miners digging the coal. But it might be well to mention what is being done to prevent blowouts or indeed other occurrences from producing an explosion that would involve the whole mine. Districts are small and each district is ventilated by a separate split. No electric signal wires or electricity of any kind are allowed in an affected area.

Barriers of inert dust (flue dust) taken from the



bottom of the smokestack at the boiler house are installed in every level and in the manway and main slope above it. These barriers consist of two 12-in. boards placed side by side and suspended by suitable hangers from the roof timbers at right angles to the roadway. They are placed 4 ft. apart and 6 ft. above the rail. From sixty to ninety of these form a battery of barriers, and each barrier contains 5 cu.ft. of inert dust. In addition to this, at every stopping in the crosscuts between levels and slopes are three of these barriers, each containing 5 cu.ft. of inert dust.

The flue dust has a specific gravity of 0.66 and more than 50 per cent will pass through a 100-mesh screen. In addition to this the intake air is heated on entering the mine by coils or radiators consisting of 4-in. pipe through which exhaust steam from the hoisting engine outside flows into the mine. By means of a bypass, arrangements have been made so that when not hoisting sufficient live steam is allowed to pass through the radiators and enter the intake airways. The steam on the intake does not interfere with the rope runners, for it is arranged so that these men do not come outside with the cars. A man stationed outside detaches the trip and sends the empty cars back into the mine.

A number of very fine fog sprays are placed at 100-ft. intervals on the main haulage roads. These are operated automatically by a large cistern and float arrangement by means of which the sprays are in operation 20 minutes out of every hour. This time for automatic spraying may be arranged at will. The flue dust also is scattered by hand on the ribs and timbers, and of course in applying it a large quantity is deposited on the floor. The fine coal from some of the outbursts assays 50 per cent ash.

Direct-Connected Centrifugal Pump For Construction Work

CONSTRUCTION is the one part of the mining problem to which in many instances but little care and attention is given, and many an operation is started without much equipment other than a few picks and shovels, an auger, a stump puller, a few wagons and some dynamite. One of the first troubles is water, which soon makes its appearance, perhaps in some prospect hole, a waterline trench, the excavation for a bridge pier, an engine or building foundation or a cellar. To remove this water the Evinrude unit centrifugal pump of the Evinrude Motor Co., Milwaukee, Wis., is well suited by reason of its extreme simplicity and the ease with which it is set in operation. The magneto is set at the top of the unit and is of the built-in flywheel type. The power is generated by the explosion of gasoline, the engine being of the same build as has been used for years for motorboat propulsion. A universal joint connects the engine to the shaft, on the end of which is the centrifugal pump. There is but one moving part, the impeller, rotating in perfect balance and at high speed. This will take water either under pressure or from a lower point, the suction lift being arranged not to exceed 20 ft. The pump being free from valves, gears and sliding parts and the passages being large and unobstructed, water can flow through it in great quantity.

HANDY PUMP FOR NARROW QUARTERS

To support the pump shaft at the lower end, a ball thrust bearing has been provided.

The great simplicity of the equipment makes it so light that it can readily be transported by automobile and handled by two men. It weighs only 115 lb. As the motor uses gasoline as the propelling force it is necessary to use the equipment where the ventilation is such that it will remove rapidly and completely any carbon monoxide that may be formed. The 2-hp. type will deliver 6,800 gallons per hour on a level and 6,150 gallons against a 10-ft. head.

Precautions of New York Gas Company To Avert Coal Shortage from Strike

IT MAY be of at least local interest to learn a little of what the gas companies affiliated with the Consolidated Gas Co. [of New York City] have been doing to meet the very exacting demands which the public has been making on them—representing as they do, in a large measure, the most convenient and ready to hand substitute for anthracite coal for the household.

Notwithstanding that 400,000 tons of gas and hard coal were provided to meet strike conditions in April 1, 1922, all of which was New York Tidewater coal, it became clear that coal supplies were necessary from other sources in order to insure a supply of fuel for the winter of 1922-23.

Accordingly contracts were let for a coal bridge of 208 ft. span, using a three-ton bucket and having a capacity of 400 tons per hour, and also for an elevated locomotive crane for cleaning up large cargo sea-going vessels. A dock with 29 ft. at mean low water was constructed for receiving 6,000-7,000-ton vessels, an existing bulkhead was raised and strengthened and construction begun on June 1, while contracts were let for coal from Hampton Roads, first delivery to be Aug. 15.

This coal unloading and storing plant, located on Luyster Creek, Astoria, about three-quarters of a mile from the gas plant, was actually unloading coal from barges a few days after Aug. 15.

It was quite clear that sufficient Hampton Roads coal would not be forthcoming, so that 113,000 tons of "Wear Specials"—England's best gas coal—was contracted for f.o.b. piers England, deliveries in August, September, October and November. About 7,000 tons additional was later ordered. All the English coal but 5,000 tons has been received; 113,000 tons of it in U. S. Shipping Board vessels, with less trouble than one could have imagined possible, and at prices very favorable, considering American spot prices.

So promising had the prospect become for other than New York Harbor coal that additional wharfs and docks have been constructed, and two additional 208-ft. span bridges ordered, so that the wharfage will be 1,600 ft. long.

*From address by J. W. Lieb, vice-president, New York Edison Co., before the New York Electrical League, Feb. 28, 1923.

Chromium, Nickel and Silicon Alloys Best Resist Acidulous Mine Waters

THE results of corrosion tests on forty-five different metals and alloys in the acid mine waters from coal mines, made in the course of a co-operative investigation by the Carnegie Institute of Technology, the U. S. Bureau of Mines and an advisory board of coal-mining engineers are summarized in Bulletin 4 of the Coal-Mining Investigations series, just published by the Carnegie Institute of Technology, Pittsburgh, Pa.

Water from coal mines usually is decidedly acid in character and causes much trouble and expense by its corrosive action on mine equipment. These waters contain free sulphuric acid, and ferrous, ferric and aluminum sulphates, sulphates of calcium, magnesium, sodium and potassium, and in addition silica and usually some chlorides. On standing, dilution, aëration or warming, insoluble iron compounds tend to precipitate, principally as hydrous ferric oxides. The presence of iron sulphates and free sulphuric acid is due to the action of water and air on the pyrite or marcasite associated with the coal. These substances are oxidized to ferrous sulphate, ferric sulphate and sulphuric acid.

In the co-operative investigation made by the U. S. Bureau of Mines and the Carnegie Institute of Technology three test specimens of each of forty-five metals and alloys were completely immersed in flowing water at each of three coal mines in western Pennsylvania for periods ranging from 98 to 135 days. The waters from these mines covered a wide range of acidity, from one considered to be below the average of that region to a water which is considered to be extremely acid. Inspections were made at regular intervals, and the degree and nature of corrosion was noted. At the completion of the test the specimens were removed, cleaned and the extent and nature of the corrosion recorded. Samples of the mine waters were collected at each inspection and the degree of acidity determined. Complete analyses also were made on the waters from the three mines.

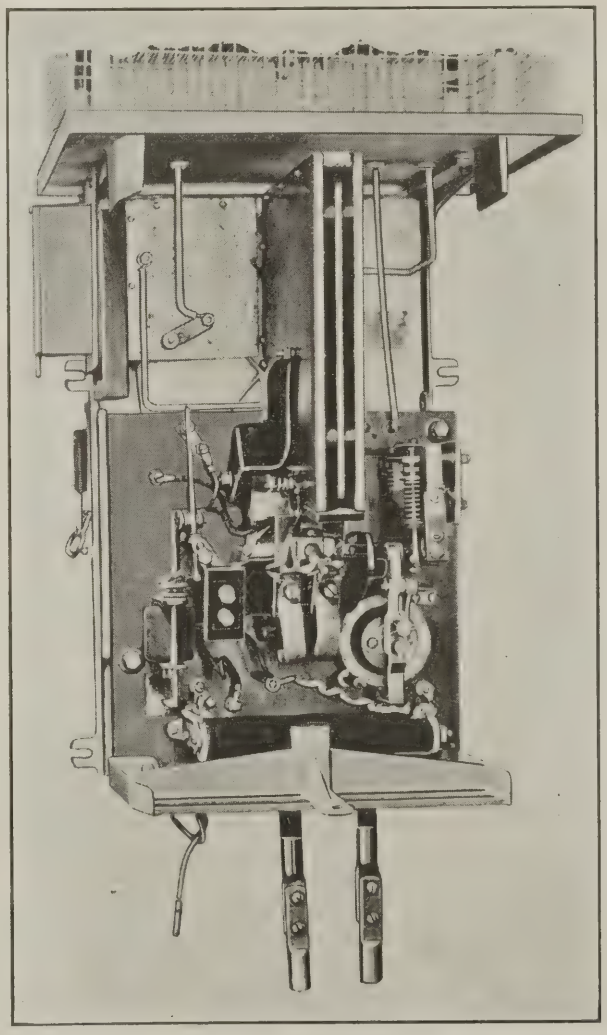
Copper-Tin Better than Copper-Zinc Alloys

All the alloys of the brass type, which contained much zinc, when tested, were corroded extensively by the mine waters. Bronzes, containing much tin, also were corroded, but less than the brasses. Evidently copper-zinc alloys are less desirable for use in mine water than copper-tin alloys. Copper-nickel alloys were corroded about as much as the brasses. Nickel-silver alloys, which contain copper, zinc and nickel, also were corroded extensively. Aluminum alloys showed a marked tendency to pronounced pitting.

The materials which showed a marked resistance to the corrosive action of the acid mine waters include a high-chromium steel, two highly alloyed chromium-nickel-silicon steels, a high-silicon cast iron, and a nickel-chromium-iron alloy. All these materials, except the high-silicon cast iron, contain large quantities of chromium. These resistant materials have certain disadvantages for general use in coal-mine equipment, such as brittleness and hardness in case of the high-silicon cast iron and relatively high cost in case of the others; nevertheless, these resistant materials should prove satisfactory for use in pump parts and other equipment where these factors are not a serious consideration.

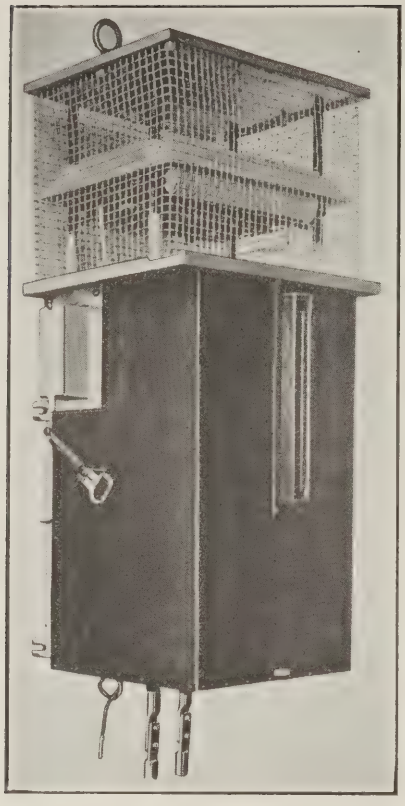
Economic considerations, such as cost, ease of fabrication and physical properties, will be factors in determining the suitability of a metal or alloy for use in equipment exposed to the action of acid mine water.

Bulletin 4, which has been prepared by W. A. Selvig, assistant analytical chemist, U. S. Bureau of Mines, and George M. Enos, research fellow, Carnegie Institute of Technology, may be obtained from the Carnegie Institute of Technology, Pittsburgh, Pa., at a price of 40c.



Self-Acting Reclosing Circuit Breaker With Arc Chute and Blowout Coils

By D. J. Baker*
Charleston, W. Va.



A NEW type of automatic reclosing circuit breaker known as the "MSB" and having all of the operating characteristics of the familiar tie-feeder switchboard instrument is now available for mine-sectionalizing service. The new automatic circuit controller which is being manufactured by the Automatic Reclosing Circuit Breaker Co., of Columbus, Ohio, was designed exclusively for outside- and inside-mine duty.

All of the operating parts are front-connected on an ebony-board panel and are so related as to be easily accessible. The panel and a wire-enclosed nichrome resistance unit are mounted on a cast-aluminum frame

*West Virginia manager, the Automatic Reclosing Circuit Breaker Co.

BREAKER PARTS READILY ACCESSIBLE
All parts are arranged on the front of the panel, thus giving easy access for adjustment and quick repairs without any undue inconvenience.

ENCLOSING CABINET WITH SCREEN OVER RESISTANCE
Proper protection is afforded by safety, and resistance unit is well ventilated.

so that the complete outfit may be both compact and light in weight. Two resistance tubes at the bottom of the panel liberate sufficient heat to assure that the operating mechanism will be prevented from rusting or corroding regardless of where the installation may be made. The instrument is rated at 60 amperes for either 250- or 550-volt service but ranges in its overload calibration from 300 to 1,200 amperes. On opening the breaker the arc is broken in an asbestos chute near a magnetic blowout coil. The unit is provided with a black-enameled sheet aluminum enclosing cover which may be locked. A push-button control switch is located in a housing on one side of the cover whereby means is provided for locking the breaker out permanently when desired. The new instrument permits of an exceedingly easy installation, as only three connections have to be made, two of these being positive. These two are used to connect the sectionalizing breaker in series between two sections. The third connection is bonded onto the rail or into the return circuit. Another important feature of the breaker is that it may be used for stub-end or independent feeder service.

An exceedingly wide field of application is being found for the new circuit breaker, which is about half as elaborate as one of the regular switchboard breakers of the same rating. It permits of an automatic sectionalizing scheme being adopted within the mine so that power disturbances in the troubled section do not affect the entire distribution system and thus cause the breaker to open at the substation, with the subsequent stopping of operations from face to tipple. Overloads and short-circuits are automatically confined to their points of origin.

The breaker further permits of feeder and trolley lines being tied together wherever possible for the purpose of boosting the voltage back at the working places, yet giving the various load centers an entire freedom from trouble in event of line or feeder disturbance in another section of the mine.

The instrument opens on a current value corresponding to the setting on the overload adjustment bracket, remains out a definite and adjustable time interval, and then operates to reclose, providing the cause of the overload has been removed from the line. If a short-circuit has opened it, the breaker "locks out" until the "short" has been cleared up. In this connection the instrument also is adjustable so that it may be set to reclose against a predetermined legitimate dead load on the section it controls.

Selective service on various feeders may be obtained by employing the breakers in conjunction with overload relays of either the instantaneous trip or time-cycle type. In this case, when it is desired to divert a high current value to a particular section in order to handle a peak load over a definite or indefinite time cycle other and lesser important sections may be dropped automatically and picked up again when the demand is over. This is especially desirable in plants having heavy grades along their main haulageways where peak loads on these main haulageways combined with other loads would otherwise result in opening the breaker in the substation and thus suspend operations throughout the mine.

Several installations of this nature already made have precluded the immediate necessity for purchasing additional generating equipment, and have maintained higher all-day load factors.

Morbidity Studies as an Aid in Preventing Illness Among Miners*

By R. R. Sayers†

NINE operators and managers for a number of years have known that the maintenance of the health among the workers has an appreciable financial value. In order to maintain the health, it has been found necessary to know: (1) The health hazards existing in the industry as a whole and the specific hazard in the individual mine. (2) The physical condition of applicants for employment as well as that of the old employees. This can be determined only by systematic physical examination of all applicants and of regular employees at intervals of at least once a year thereafter. (3) All cases of sickness that occur among the workers.

No operator or manager, or personnel, medical or safety organization can control or prevent sickness without knowing where, when and under what conditions the sickness actually occurs. In order to obtain information as to the hazards of industry, investigations have been and are being made of the effects of the conditions both in the field under usual working practices and in the laboratory. In the field several factors generally are present which affect the health. The effect of these factors may be determined by studying each of them separately in the laboratory. However, both the field and the laboratory studies are limited in value in that such studies usually have been made over a comparatively short period. While we have some information as to their immediate effect, we do not know to what extent extreme heat, humidity, the presence of dust or other health hazards are the cause of disability.

TABLE I—MORTALITY AMONG INDIANA COAL MINERS (a)

Year	Persons Employed At Coal Mines	Deaths	Rate per 1,000
1916	21,300	260	12.21
1917	23,940	323	13.49
1918	27,932	515	18.44
1919	28,673	291	10.15
1920	27,076	348	12.85

(a) Data taken from the annual reports of the Indiana Industrial Board.

*Report of Subcommittee on Prevention of Illness of the American Institute of Mining and Metallurgical Engineers, New York meeting, Feb. 19-22, 1923.

†Chief Surgeon U. S. Bureau of Mines; surgeon U. S. Public Health Service.

TABLE II—PERCENTAGES OF TOTAL DEATHS IN INDIANA AMONG COAL MINERS, FARMERS AND ALL OTHER MALES, GROUPED ACCORDING TO CAUSE, 1916-1920

Cause of death	Miners	Farmers	All Other Males
Typhoid fever	1.15	1.39	1.19
Influenza	11.10	6.34	5.60
Pulmonary tuberculosis	6.45	7.71	12.90
Other tuberculosis	0.86	1.49	1.19
Other respiratory diseases	9.15	9.10	10.08
Diarrhea	0.75	1.57	1.23
Syphilis	0.63	1.11	1.52
Cancer	3.51	7.10	5.16
Alcoholism	0.63	0.08	0.53
Apoplexy	3.28	9.32	7.43
Other diseases of the central nervous system	1.67	4.19	2.97
Diseases of the heart	8.75	15.71	14.05
Other circulatory diseases	1.15	3.56	3.03
Append. & Int. Obstruc.	1.50	1.62	1.77
Cirrhosis of the liver	1.09	0.78	1.64
Nephritis	5.00	11.52	9.64
Suicide	1.73	1.14	1.48
Mine accidents	26.20	.....	.....
Other accidents	9.78	5.18	7.87
All other causes	5.64	11.12	10.60

Mortality statistics probably are the most easily available indices as to the hazards of industry. As an example, a study of such statistics among coal miners of Indiana shows a marked increase in the death rate in 1918.

The increase in the death rate in 1918 was not entirely due to the industry but to the general epidemic of influenza. However, the proportional death rate of miners for the five-year period 1916-1920 shows that 11.1 per cent of the deaths were caused by influenza, as compared with 6.34 per cent of the deaths due to the same cause among farmers and 5.6 per cent among all other males.

While the miners had a larger percentage of deaths due to influenza over the five-year period than either of the other groups, the percentage due to accidents was the most striking. More than one-fourth (26.2 per cent) of all deaths among miners was the result of mine accidents, largely falls of roof, coal, rock, etc., and explosions. About 10 per cent (9.78 per cent) were due to accidents other than mine accidents, as compared to 5.18 per cent among farmers and 7.87 per cent among all other males. While proportional death rates may be somewhat misleading, it is quite evident, when almost 36 per cent of all deaths are due to one cause, accidents, where the greatest efforts to save life should be made.

While the data obtained from morbidity statistics are of material aid in the prevention of sickness, they only show the last illness and give no information as to previous health conditions of the individuals. Furthermore, no information is given as to the exact nature of their work other than a general statement as to occupation. It is this limitation of the knowledge supplied by death certificates that makes sickness records so necessary to lessen or eliminate the health hazards of an industry.

All operators are interested in knowing how much working time is lost by the employees and how much of this absenteeism is due to sickness. Many of the larger companies, and some of the smaller ones, have the requisite organization to determine the effect of different kinds of work and working conditions on those exposed in terms of frequency and severity of disability. Some plants now obtain this data and use it; others obtain it but make little or no use of it. One lead smelter in the United States has a full-time medical and safety organization which makes physical examinations of all applicants for employment and at intervals thereafter. Sickness records are kept of all illness. This company decreased the yearly incidence of lead poisoning from 87 to 35 cases in four years.

Usually there is no valid reason why companies having a full-time plant or mine physician cannot record what is happening to the health of the population in which they are interested. Records of sickness, of course, are kept in practically all establishments which provide medical service for employees, but usually they cover only those cases that are treated in the plant dispensary or company hospital. Obviously, a record of *all* the cases occurring in the population under study is necessary for determining the relative frequency and severity of disease according to occupation. It also is necessary to have available the same set of facts for the persons not sick as for the persons sick so that comparisons can be made in terms of rates per 100 or 1,000 persons in any given period. A card (5x8 inches), used by the U. S. Public Health Service and several large industrial plants, is suggested as being suitable. Reprint 573, Public Health Reports, gives an explanation of the terms used on this card.

INDUSTRIAL MORBIDITY FORM A, STATISTICAL OFFICE, U. S. PUBLIC HEALTH SERVICE (REVERSE SIDE OF CARD)

The card shown will serve as a record of personnel and of sickness among the personnel. To be of current value it is necessary to put in monthly tabular statements the number of personnel, the number of cases of sickness occurring among them, and the sickness rate per thousand persons for any group desired. The record of sickness may be obtained from the card without difficulty if signals distinct from personal signals be attached.

The Public Health Service,‡ in co-operation with the U. S. Bureau of Mines, is prepared to assist companies which wish to inaugurate a system of morbidity records by sending a representative to confer with the company and to help revise a plan of records. The co-operation of the employment department and the medical department of the company in the keeping of

‡Information supplied by D. K. Brundage, assistant statistician U. S. Public Health Service.

morbidity records is essential. There must be a card for each employee, whether he is ever sick or not, containing much the same personnel data as are recorded in the employment department: Age, nationality, length of service with the company, etc. These facts about the employee must appear on the same card showing the chronological record of disability in order to make possible the correlation of cases of sickness with age, length of service, etc.

Canadian Mining Institute Discusses National Fuel Supply of Dominion

By W. A. Lawrence
Montreal, Can.

CANADA is perplexed over its fuel supplies from the United States and, as a result, there is an insistent demand from some of the leading dailies that she take time by the forelock and either insure a sufficient supply without depending upon the coal fields of the United States, or, better still, find substitutes for the fuel now being used.

That the matter is one of grave concern to the Canadian people was borne out by the fact that the Canadian Institute of Mining and Metallurgy, at its annual meeting in Montreal, March 7-9, devoted the entire session, extending over three days, to a discussion on the fuel situation. Many of the leading fuel experts of the United States were in attendance and presented well-considered views on the relation of the United States to Canada in so far as fuel supplies are concerned.

Undoubtedly the Canadian consumers—they purchase 22,000,000 tons a year from the American coal fields—are seriously perturbed; so much so that they have even gone to the limit of accusing the American operators of discrimination. In this unqualified charge, however, they have lost sight of several important facts, as papers, delivered by American experts, indicated.

United States Giving Canada Fair Quota

For instance, George H. Cushing, of Washington, in his paper on "United States Bituminous Coals Available for Canada," pointed out that the recent shortage in Canada was not due to a malignant desire on the part of United States operators to hold up their Canadian customers. Rather it was due to factors over which they had no control, and, further, it amounted, in the opinion of Mr. Cushing, to an almost unpardonable libel to suggest that American dealers were unfair.

As he pointed out, the coal shortage was due to the simultaneous expiration of the contracts between union miners and union operatives, "a combination of circumstances which is hardly likely to recur."

When the coal situation as between Canada and the United States was brought down to the fine point, as Mr. Cushing explained, it was essentially a matter of transportation. As he said, "I believe it is going to prove easier to buy coal than to have it carried," which disposed of this matter almost in a nutshell.

Enlarging on the problems facing the American operatives, he recalled how, in the earlier stages of the war, the United States inevitably was forced into supplying the needs of the allies as a result of which it accumulated a large working surplus. This was invested in the ownership of mines and factories. Unfortunately, one fatal mistake had been made; rail transportation had not been developed commensurately with the progress of industry. The merchant marine, however, had been greatly overdeveloped.

"Putting it bluntly," he said in his summary on this point, " we have far and away enough coal productive capacity to satisfy all Canada's demands for fuel but we have such comparatively small rail transportation facilities that we cannot take care of our own needs and Canada's unless we both apply ourselves assiduously to the development of our water-borne traffic."

American operators, he contended, were forced to select customers who were so situated as to assure the quickest return to the mines, but, he thought, Canadians could help by insisting upon a quick return of coal cars.

Must in Future Do with Less Anthracite

J. F. K. Brown, chief engineer of the Hudson Coal Co., dispelled a few illusions also in his paper on the "Relationship of the Anthracite Fields to Canada," the first one of which was that there had been no progress in coal-mining operations. He pointed out that, owing to the diminishing supply of anthracite, it was likely to be extensively supplanted by soft coal and other fuel. As regards this possibility, he thought any change will come about gradually and it will be taken care of by the consumer, who, as time goes on will create a demand for another and more economical method of heating as he finds that the cost of his present system slowly increases.

Costs of production naturally will increase because the best coal has long since been mined and, of necessity, operators now have to dig deeper and use more expensive machinery to meet their requirements.

R. J. Lee delivered an address on the "Lignites of Saskatchewan." He stated that the deposits were discovered in August, 1857, by Dr. Hector and Captain Palliser, of the Palliser expedition, who had heard reports as to the presence of the mineral from Indians and half-breeds. In 1880 Hugh Sutherland shipped coal by barge down the Souris River and other waterways to Winnipeg.

The principal lignite mining region in the province of Saskatchewan is around Bienfait, Estevan and Roche Percée. Here are four seams varying from 3½ to 15 ft. in thickness, the average being 8 ft. From this area 90 per cent of the present lignite production of Saskatchewan is produced.

Roof Too Weak for Longwall Workings

Longwall has not been found successful, probably because there is no solid rock formation between the tops of the seams and the surface. No difficulty has been experienced, however, in working rooms to a width of 25 ft. No inflammable gas has been encountered, but fires, says Mr. Lee, have broken out at several of the mines and, in the spring, water is a source of trouble, as it readily enters the mines through the light surface cover. The plants in aggregate could produce 3,000 tons per day if they could find a market for their product. When the lignite is dried and pulverized it is extremely liable to spontaneous combustion, which makes it difficult to store. It also reabsorbs moisture freely. This interferes with its use pulverized. Certain technical difficulties have been found to interfere with the briquetting of dried lignite. Briquets have been made containing: Moisture, 6 per cent; ash, 14 per cent; volatile matter, 16 per cent; fixed carbon, 64 per cent. The fuel gives 11,700 B.t.u.

D. B. Dowling, of the Canadian Geological Survey, adds Mr. Lee, estimates the total lignite resources of

Saskatchewan at 58,000,000,000 metric tons. This estimate includes all coal seams of 1 ft. or over and to a depth of 4,000 ft. The lignite has 33 per cent of moisture, 27 per cent of volatile matter, 7 per cent of ash, 33 per cent of fixed carbon and 9.5 per cent of sulphur, and delivers 6,500 to 7,500 B.t.u. The lignite is sold at a low figure, for whereas the average selling price of coal at Canadian mines is $4.97 per ton the average selling price of Sasketchewan lignite is $2.40 per ton. So far the field has conducted its operations without lengthy strikes.

Ontario Has the Most; Quebec the Best Peat

B. F. Haanel, in an exhaustive paper on the "Peat Resources of the Central Provinces and Their Utilization for Fuel Purposes," said:

"The peat resources of Ontario are estimated to cover approximately 10,450, those of Manitoba 500, and those of Quebec 500 square miles, but of this large area only a very small portion, favorably situated with respect to inhabited communities and transportation facilities, has been surveyed and examined in detail. Only this portion, therefore, will be considered in discussing the value for fuel purposes of the peat in the central provinces.

"Eighty-eight peat bogs situated in this part of Canada, with a combined area of 330 square miles and representing 114,000,000 tons of standard peat fuel, have been examined in detail. Forty-six of these bogs are situated in Ontario, 27 in Quebec and 9 in Manitoba.

"The calorific value of the bogs examined so far in the Province of Ontario varies between 7,000 and 9,000 B.t.u. per pound. It is noteworthy that the peat of the bogs so far examined in Quebec appears to be of a better quality than that found in Ontario, the heat content varying between 9,000 and 9,760 B.t.u. per pound. In every case the heating value refers to absolutely dry peat. This is a very high heating value for Canadian peat and compares favorably with that of the peat found in Ireland. The ash content of the Ontario bogs so far examined varies between 4 and 26 per cent, but a large number of the bogs have an average ash content around 6 to 7 per cent. Here again the advantage appears to rest with the peat bogs of the Province of Quebec; their ash content is exceedingly low, varying between 2 and 8 per cent, and the average percentage of ash in all the bogs of that province is considerably below 8 per cent.

Low Ash and Sulphur and High Nitrogen

"Chemically, peat differs markedly from solid fuels in that it has a high percentage of oxygen—about 33 per cent—a high content of volatile matter, a low content of fixed carbon, and generally a comparatively high content of free nitrogen. The latter makes peat fuel especially valuable for utilization in a byproduct-recovery gas producer, in which over 70 per cent of the nitrogen of the fuel may be recovered as ammonia. The sulphur content of peat is very low; almost negligible.

"Peat coke for this reason is a most desirable metallurgical fuel. The ash content is not only low, as a rule, but non-fusible under ordinary conditions; therefore high temperatures can be maintained without the production of troublesome clinkers. The heating value, as already stated, is determined for absolutely dry peat, but when peat is used as a fuel its moisture content varies up to 40 per cent.

"If the raw-peat substance contains 88 per cent water and 12 per cent combustible substance—that is, 240 lb. of combustible matter and ash per 2,000 lb. of raw peat—and if the heating value in the absolutely dry state is 9,000 B.t.u. per pound, there would scarcely be sufficient heat available to evaporate the moisture content, assuming perfect drier efficiency and that this heat could be made available.

"The evaporation of the total water content by the application of artificial heat has not proved economic, and it has been amply demonstrated that the bulk of the associated water must first be removed by other means before artificial heat can be employed for removing the remaining moisture. In drying at atmospheric pressure, the larger part of the heat required is represented as latent heat of steam, namely, 970 B.t.u. per pound of steam formed, and this heat in practice is totally lost.

Drying by Artificial Heat Unprofitable

"Several attempts have been made in Canada and other countries to briquet raw peat when dried below 10 per cent moisture, without the employment of a binder, the object being to produce a compact and more attractive fuel and one in which the rate of combustion would be less rapid than is the case with ordinary air-dried machine peat. The reduction in volume, it also was realized, would be a great advantage; but in order to furnish the dry peat for briquetting, the original water content had to be partly removed by artificial heat, as in the case described above. Much money has been expended in an attempt to perfect a process for manufacturing peat in this manner, but this money was lost, due entirely to the cost of drying and briquetting.

"Based on the performance of the experimental combination plant at the Alfred (Ont.) bog and the estimated cost of an entirely new and remodelled plant, complete with an efficient power unit and larger macerator, the production and other costs of the finished peat per ton are estimated to be:—

	10-Hr. Day	20-Hr. Day
Production costs	$2.00	$2.00
Overhead costs	2.48	1.50

"Thus the total cost of finished peat fuel on board cars at the siding of the plant would be $4.48 for a 10-hr. day, for a season of 100 days, or $3.50 for a 20-hr. day during the same season. The total production of salable fuel in the first case would be 10,000, and in the second case 20,000 net tons. Overhead costs, however, increase rapidly as the production decreases; consequently the committee recommends that plants of this type be operated for twenty hours per day. The figures for production costs include an ample allowance for cost of raw fuel, paid for on a royalty basis, and for clearing and draining the bog.

Has Half as Much Heat as Anthracite

"Standard peat fuel, as manufactured at Alfred, has a heating value of about 6,500 B.t.u. per pound, whereas the average anthracite now coming into Canada has a heating value of about 12,500 B.t.u. per pound. Standard peat fuel has a moisture content of 30 per cent.

"Theoretically, therefore, it takes about 2 lb. of peat to give the same heating value as 1 lb. of anthracite. This is based on a comparison of the theoretical heating values of the two fuels. In practice, however, a comparatively large portion of coal passes through the grates unburned, and is entirely lost, whereas the peat is entirely consumed. In mild weather, owing to the difficulty in controlling a coal fire, much heat is wasted or the fires go out. With the peat fuel this is not the

case. This is a distinct advantage which peat has over anthracite.

"The value of the nitrogen contents of our peat bogs will be better appreciated from the following calculation: The fuel content of the peat bogs examined in detail in Manitoba, Ontario and Quebec is estimated at 114,000,000 net tons of fuel having a 25-per cent moisture content. This reduced to the dry state is equivalent to 85,500,000 tons, and if the average nitrogen content is 1.75 per cent, the total quantity of free nitrogen available will be approximately 1,500,000 tons. From this quantity of nitrogen 4,900,000 tons of ammonium sulphate could be produced, assuming a recovery efficiency of 70 per cent, which would represent a total value of about $200,000,000, depending on the market price."

G. B. Saunders, a Winnipeg coal merchant, dealing with "The Problem of Replacing Foreign Coals on the Manitoba Market," strongly boosted Canadian coal, asserting that Canada should be entirely independent of American supplies. That the Canadian mines are doing better business was obvious from figures; in Manitoba alone, he declared, fully 75 per cent of the domestic coal used this winter was from Canadian mines. The Western dealer was particularly bitter toward the attitude of some of the leading institutions in the country who, with their preference for American fuel, ignored the home product.

That the American coal business was operated on ruthless lines in order to retain the Canadian market was stressed by Mr. Saunders, who spoke of price cutting by importers of American coal and dealers in order to defeat the Canadian sellers. Many of the assertions about the superiority of American over Canadian coal were fallacious, he declared, instancing several tests that have been made with the two fuels in which the Canadian product made the better showing.

Spontaneous Combustion of Stored Coal And the Conditions That Favor It

THAT the tendency of coals to fire spontaneously differs with their age, the younger coals being the most dangerous, is one of the conclusions of Joseph D. Davies, fuel chemist of the U. S. Bureau of Mines, and John F. Byrne, research chemist of the Carnegie Institute of Technology, as expressed in a bulletin published as the result of experiments and inquiries cooperatively conducted by these two institutions. No case, say they, has been recorded in which anthracite fired spontaneously; even fines and slack can be safely stored. At the other extreme is lignite, which cannot be stored, even in lumps, with safety, except under water. Between these two extremes are the various grades of bituminous coals, the class most commonly stored.

The liability of different bituminous coals to fire varies widely on account of differences in the coal; but, broadly speaking, the bituminous coals of the eastern part of the United States store better than the coals of the Middle West. These, in turn, are safer to store than the sub-bituminous coals of the Intermountain region. Though the tendency to fire will vary widely in any one class of coal, generally speaking, the higher the rank the less the danger of fire and the less the deterioration in storage. The classification as to self-heating coincides with the classification of coals, beginning with lignite as the most dangerous, ranging through sub-bituminous, bituminous, semi-bituminous, to anthracite, which is the least prone to spontaneous combustion.

The solution of the problem of spontaneous combustion may lie in the microscopic examination of coals and its correlation with the rate of heating. Coal is composed of three parts, namely, anthraxylon, or bright coal; attritus, or dull coal, and mineral charcoal, and may be separated into almost pure samples of each. These three constituents differ in their ease of oxidation and rate of heating. Tests indicate that in the spontaneous heating of coal the anthraxylon is the constituent that first rises in temperature.

As the results of the experiments of Messrs. Davis and Byrne it is stated that the presence of fines in a coal pile should be avoided. Coal should be handled as little as possible and should be screened wherever practicable before storing. Coal coarser than ¼ in. showed no rapid self-heating throughout the experiments.

The experiments show that with the same coal, moist air will give a lower "critical" or spontaneous combustion temperature than dry air. Therefore, wetting the coal pile to retard heating is not good practice unless the coal is completely immersed.

Instead of hastening spontaneous combustion, partly oxidized coal seems to act as a deterrent when mixed with fresh coal. It appears that the danger in mixing two grades of coal, or in storing coal on the same pile at different times, arises from physical rather than chemical causes. If no heating has occurred at the surface of the heap, it is safe to pile more coal on top, provided there is no accumulation of fines at the contact of the new and old coal. A mixture of two kinds of coal will heat more rapidly than either one of them.

Artificial mixtures of coal and pyrite in various proportions showed a critical temperature no lower than that of the coal alone, whereas pure pyrites had a critical temperature 26 deg. C. higher than the coal. From this it appears that massive pyrite or "brass lumps" are not dangerous in a coal pile.

Better Isolated from Air than Ventilated

On account of the low conductivity of coal, cooling by artificial ventilation is almost impossible unless the air reaches every part of the pile. Generally the air travels through the stack in currents and exerts no cooling effects on parts a short distance away from its channels. It is easier to exclude air so completely as to retard oxidation than to ventilate the pile so thoroughly that the heat developed will be dissipated.

Coals have been tested under various physical and chemical conditions to determine the temperature at which they generate heat so rapidly that, provided no deterrent is applied, the coal will eventually ignite. This temperature has been arbitrarily called the "critical temperature." Under similar conditions of heating and aërating, this critical temperature is an index of the liability of a coal to fire spontaneously. The "critical temperature" method of testing coal may be applied to the various coals of the country for grading their relative tendencies to fire spontaneously, and the U. S. Bureau of Mines expects to develop this method further and apply it in a survey of the coals of this country.

The results of these tests are summarized in Bulletin 3, Coal-Mining Investigations series, which is distributed by the Carnegie Institute of Technology, Pittsburgh, Pa., at a price of 25 cents.

Problems of Operating Men

Edited by James T. Beard

Room-and-Pillar Work in the Miller or "B" Seam

Knowledge of Conditions Needful—Soft Bottom, Characteristic of This Seam—Uniform Pillars Essential to Successful Work

REFERRING to the question asked by Robert Holt, *Coal Age*, Feb. 1, p. 226, as to whether it is better to delay the drawing back of pillars when a room has reached its limit, in the working of the Miller or "B" seam; or whether better results can be obtained by starting the work of robbing at once, allow me to submit the following:

My understanding is that the purpose of delay would be to permit all the rooms on a producing entry to reach the limit and then pull back the pillars in one continuous line. The inquirer further draws attention to the timbering being in good condition when the room reaches the limit, but fears the effect of the soft bottom, if the work of robbing is delayed.

My experience tells me that soft bottom is characteristic of the Miller seam, at least throughout the Somerset County field in Pennsylvania, which limits my acquaintance with this seam. In some instances, however, I have known the fireclay underlying the coal to be of such a composition that it will not disintegrate as rapidly as it does in other localities. A thin stratum of coal underlying the clay, in places, gives a greater firmness to the material and enables it to better resist the increasing pressure when the coal is taken out.

Development of Mine Is Invariably Accompanied by Squeeze

However, in every instance in my experience, a fairly extended development has been accompanied with a more or less pronounced squeeze. This fact has led me to conclude that it is always safe to anticipate the occurrence of a squeeze, in working this seam, and to adopt every precaution to reduce its effect to a minimum.

Assuming that the mine is worked advancing on the room-and-pillar system, as I believe is the case in this instance, the tendency to squeeze can be considerably reduced by the maintenance of uniform pillars throughout the mine, particularly the pillars between rooms. While this is easy to suggest and in strict conformity with the principles of good mining practice, its application is not so easy in the working of this particular seam.

Unfortunately, the Miller seam is characterized by numerous rolls, which make it absolutely necessary, at times, to narrow the width of the rooms, or even change their direction, in order to overcome this obstacle. In other words, it is difficult to always drive the rooms on sights, under the conditions that prevail in the Miller seam.

Let me suggest, here, that it is always advisable to adopt a uniform system of posting that will make it possible to maintain the prescribed width of the room and thickness of pillars. My experience has proved that such a regular system of posting distributes the roof pressure more uniformly and the posts will continue to support the roof a longer time without breaking, and there is less evidence of coming squeeze than when the timbers are set in a haphazard way.

A seam of this thickness, 3½ ft., will not develop a surface break, until a large area has been extracted, if it does then. Extracting pillars as the rooms are finished, will throw a great weight on the remaining room stumps as well as on the chain or barrier pillars, and a squeeze will be almost inevitable. If that occurs an unavoidable loss of coal will follow as many of the remaining stumps and pillars cannot be taken out with safety.

On the other hand, if the pillars be left until the roomwork is completed on an entry, the chances are more strongly in favor of an extended squeeze occurring very shortly after the work of drawing the pillars is commenced. Unless very wide pillars are left, there will be no solid coal of sufficient dimensions to cause a break that will relieve the pressure and avoid the squeeze that is imminent and certain to prove disastrous to the future working of the mine.

Choice Lies Between Two Evils

Out of two evils, therefore, we will choose the least. My judgment is that there is less danger to be anticipated, under these conditions, if the work of robbing the pillars is commenced at once when a room reaches its limit. It is always a judicious course, however, in a case like this where it is necessary to choose between two evils, to carefully explain the possibilities in each proposition. It should be understood, beforehand, that the method chosen will not eliminate loses that are sure to follow, in the working of the seam by reason of conditions that cannot be wholly overcome.

A study of these conditions that so generally prevail in the Miller or "B" seam, has shown to me that one thing liable to occur is the sudden breaking of the roof strata where it might be least expected: namely, in advance and isolated narrow work. Such has been my personal experience, on several occasions, and I have discussed the cause of these sudden breaks with a number of mining men.

Those with whom I have conferred have expressed themselves as believing that the cause of such breaks was either gas or water pressure, though neither of these were manifest, at the time of the occurrences or later, in sufficient volume to warrant this conclusion. It would be of interest to learn the thoughts of others regarding the cause of these sudden breaks, in driving advance headings in this seam.

I. C. Parfitt.

Washington, D. C.

Electric Cap Lamp in Firebossing

Lamp has no value for testing for gas—Bright light blinds the eyes—Requires too much time to screen light when making a test.

IT HAS been a surprise to me that so many of the writers in *Coal Age* have professed a preference for carrying an electric cap lamp on their heads when making their rounds as firebosses in mines. I heartily agree with O. G. Sharrer, whose letter appeared in the issue Nov. 30, p. 779, when he says: "Any official whose duties require him to test for gas in the mine should carry no other lamp than an approved testing lamp."

The electric lamp has no value for making a test for gas. It is my belief that should a fireboss carry such a lamp in his cap when making his early rounds in the morning it would prove a menace in more ways than one. It is well known that most firebosses have large districts to cover, which keeps them on a constant run.

Reasons Why Fire Bosses Should Not Carry Electric Cap Lamps

On account of the limited time for making the examination, the fireboss has no time to spare to hide his cap lamp when wanting to make a test. The bright glare of the electric lamp obscures his vision and he is unable to see the faint gas cap that may form in his safety. Many firebosses will take chances, under such conditions, and not make any effort to screen their electric lamps, which thus become a menace to safety.

Taking these things into consideration, I consider it both wrong and dangerous for any fireboss to carry an electric lamp in his cap when examining a mine for gas. He should have with him, in his morning examination, no other than an approved safety lamp. This conclusion is the result of a wide experience in firebossing, first in England and then in West Virginia mines.

As fireboss, I never used any other lamp than a safety lamp of approved type. In the examination for gas, I have always regarded an electric lamp as a menace to the safety of everyone employed in the mine.

In some mines where I have firebossed, it was necessary for me to shed my coat, vest and overshirt while making my run of the district in my charge. Even then my undershirt and trousers would be wet from the perspiration that poured from my body.

Bay City, Mich. William Dickinson.

Working Coal with Soft Bottom

Must guard against squeeze and creep—Two methods of working proposed—Retreating panel system—Narrow rooms with wide pillars—Longwall conveyor face.

WITHOUT a more intimate acquaintance with the situation, it is difficult to give an intelligent answer to the inquiry of Robert Holt, *Coal Age*, Feb. 1, p. 226, regarding the working of a coal seam having a soft bottom and a fairly strong roof, such as he describes in reference to the Miller or "B" seam, in Pennsylvania.

Experience teaches that the main things to guard against in the room-and-pillar method of working under the conditions described, is the occurrence of creep or squeeze. Creep is the result of leaving too small pillars for the support of the roof, in the first working, when either the roof or floor, or both, are soft and of a yielding nature.

As the work of extracting the coal proceeds, the pressure on the supporting pillars is increased in the ratio of the area being worked, to the area of the pillars that remain. If half the coal is taken out in the first working, the pressure on the remaining pillars is doubled and, as a consequence, they are forced into the soft bottom. The roof sags and the bottom heaves.

Difficult and Often Impossible to Stop Squeeze When Once Under Way

Mining men who have had these conditions to contend against know that when a squeeze is once started it is difficult to control. Timbers are broken and the pillar coal crushed, making it difficult or impossible to recover that coal with safety.

Following these general remarks, I have two propositions to present in respect to working a seam of coal under the conditions named. They are: 1. The adoption of a modified panel system on the retreating plan, employing the room-and-pillar method of working out the panel. 2. Arranging a conveyor face, say 500-ft. in length, in working out the panel.

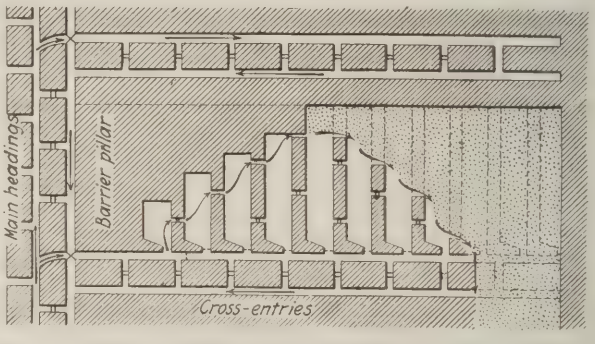

FIG. 1. ROOM-AND-PILLAR SYSTEM, PANEL METHOD

Describing Two Methods of Working a Panel

As shown in Fig. 1, the room entries are driven up to the boundary line of the panel, or a distance that will allow of driving, say thirty rooms in the panel. No rooms are turned, however, until the entries reach the boundary where the first rooms are started, the plan being to work out the panel on the retreating system.

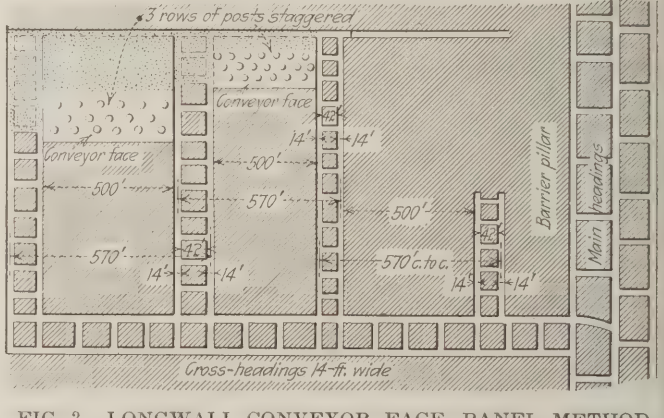

FIG. 2. LONGWALL CONVEYOR FACE, PANEL METHOD

As each room reaches the limit, the work of drawing back the pillar is begun at once. If the pillars are left to stand there will be danger of starting a squeeze, which would hinder the work and cause a loss of much coal. As each pillar is finished, the work of taking out

the entry pillars and stumps should follow immediately, care being taken to keep the line of pillar work uniform across rooms and entries.

In Fig. 2 is shown the method of working out the panel by establishing a longwall face, using a conveyor to transport the coal along the face. As before, the entries or headings are driven the length of the panel. At that point, two rooms are turned and driven up to the full depth of the panel, say from 60 to 75 yd., depending on the conditions in the roof and floor.

At the same time, two other rooms are started at a distance of 500-ft. outby. Like the first, these rooms are driven up to the limit of the panel. The two pairs of rooms are then connected by driving across the face of the coal.

When this connection has been made, a conveyor is installed and the entire block of coal between the two pairs of rooms worked back to the headings. As shown in the figure, while this is being done another pair of rooms is started and driven up to the limit of the panel, Here, a second longwall conveyor face is formed and worked back in the same manner as the first.

In closing, let me say that it is important to keep in mind that success in mining coal under the conditions mentioned, depends on driving narrow places with wide pillars and working back on the retreating system, whether the coal is worked out on the room-and-pillar system or by a longwall face. Every precaution must be taken to avoid starting a squeeze or creep. In no case, should the work of drawing back the pillars, as each room reaches its limit, be delayed. In my opinion, this would be particularly disastrous to the roads and timbers where the bottom is wet.

In adopting the longwall plan, the face of the coal can be worked out square with the panel, or on a diagonal line, as may best suit the conditions in the coal. In any case, the small pillars formed, in driving each pair of rooms when laying out the panels, should be brought back in line with the longwall face. Either of the plans proposed, will, in my judgment, require less narrow work and result in a larger extraction of coal than is possible otherwise, while at the same time making a squeeze less liable. W. DICKINSON.

Bay City, Mich.

Inquiries Of General Interest

Making a Test for Gas in a Room

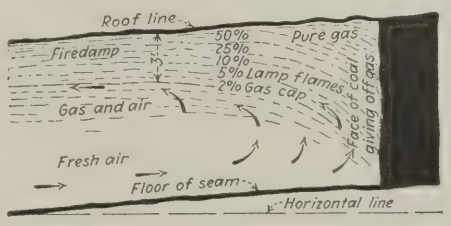
Dispute with Reference to Being Able to Find a Few Inches of Gas at the Roof of a Room When the Layer of Gas Is Too Thin to Feed Into the Lamp

A FEW days ago I was an interested listener to an animated dispute between two men who bore reputations for being practical mining men, but who appeared to hold radically different views on a matter pertaining to the testing for gas in a room or chamber.

For the purpose of the argument, we will assume the coal seam was flat. The question in dispute had reference to a thin layer of gas at the roof of a room. It was assumed that the test was to be made with a bonneted Koehler lamp. One of the men claimed that, with this lamp, he could detect the presence of any gas at the roof, although it might be but a thin layer extending an inch or so below the roof.

Both men used the term "inches of gas," in its general acceptance in the practice of firebosses. Six inches of gas would mean that the lamp flame gave the first indication of the presence of gas at a point six inches below the roof line. The first man's theory was that the gas, even if but a thin layer was there, would naturally descend and enter the lamp and its presence would be manifest on the lamp flame.

The second man claimed, on the other hand, that the gas being lighter than air would not naturally flow down and feed into the lamp, as such action would be contrary to physical law. He stated that unless the layer of gas was 9 in. in thickness, so that it would reach the ports where the air and gas fed into the lamp, a proper test could not be made that would show the presence of the gas.



Judging from the conservation, both men appeared to understand the situation alike; but, while one claimed that the gas would descend from the roof far enough to feed into the ports of the lamp designed for the entrance of air, the other claimed that this would be contrary to the laws of nature, inasmuch as the gas was lighter than air.

The fact that these men are both regarded as authorities on such a question, leads me to ask the opinion of *Coal Age* regarding the question presented.

Pittsburg, Kan. AN ANXIOUS LISTENER.

While it is true that the lighter density of the gas gives it a tendency to ascend and causes it to follow the roof line as closely as possible, it is likewise true that there is taking place a constant diffusion of the gas into the air below. As has often been explained in the columns of *Coal Age*, this diffusion of the gas into the air makes it impossible to maintain a definite line of separation between the gas and the air.

Assuming a generally flat seam, gas that may issue from the face of the coal at the head of a room or

SHOWING MOVEMENT OF GAS AT WORKING FACE

chamber will rise and travel along the roof as a thin layer of gas. But, at the same time, diffusion is constantly taking place between the gas and the air, so that there is no marked line of division between the two. A common practice among firebosses is to report a certain number of inches of gas found at or near the face of a room. This method of reporting the gas, however, is only suggestive of the condition that actually exists in the room.

In order to make more clear the situation, we here repeat an illustration that has been shown in previous issues of *Coal Age*. The dotted lines shown in the figure make plain the movement of the gas from the

face in a generally upward and forward direction and the decreasing percentage of gas from the roof downward is likewise indicated.

In reply to the question in dispute, it can be said that it would be generally impossible to walk under a layer of gas in a room or chamber without disturbing the gas more or less and causing it to descend in the wake of the person as he moves toward the face of the chamber.

Assuming, however, a still quiet condition where there is no appreciable disturbance of the layer of gas, it would be hard to detect, say two or three inches of gas at the roof, using the Koehler lamp and holding it in an upright position. A common practice among firebosses is to blow gently toward the roof, which disturbs the gas and causes it to descend and enter the lamp.

Examination Questions Answered

Examinations Under the Mines Act, Alberta, June, 1922

(Selected Questions)

QUESTION—*The quantity of air entering a mine at the intake is* 150,000 *cu.ft. per min., at a temperature of* 40 *deg. F., barometer* 28 *in. The quantity leaving the return is* 178,000 *cu.ft. per min., at a temperature of* 70 *deg. F., barometer* 28 *in.; what is the percentage of gases in the return air?*

ANSWER—For the same barometric pressure, the volume of air and gas is proportional to the absolute temperature, which gives for the expanded volume of the air current, in this case, 150,000 (460 + 70) ÷ (460 + 40) = 150,000 (530/500) = 159,000 cu.ft. per min. In this case, the volume of gas given off in the mine is 178,000 — 159,000 = 19,000 cu.ft. per min. The percentage of gas present in the return current is, therefore, 100(19,000/178,000) = 10.7 per cent, nearly.

QUESTION—*What are the chief causes of accidents from blasting in mines where shotfiring is done and the mine is known to give off methane* (CH_4) *and where a considerable amount of coal dust is produced? What steps would you take to prevent them?*

ANSWER—The chief causes of accident in blasting coal, in mines generating gas and dust, are the failure to make and enforce strict rules and regulations regarding the kind and weight of powder used and the inspection, charging, tamping and firing of shots. The excessive use of powder or the mixing of different grades of powder in the same hole; the firing of two or more shots at the same time in a close place; shooting in the presence of gas or accumulations of dust at the working face; the misplacing of shots, or shooting coal off the solid and many other causes give rise to blownout shots and produce local explosions of gas and dust that are dangerous.

Under the conditions named a maximum degree of safety is derived by the employment of shotfirers who shall examine charge and fire all shots drilled by the miners, after the men have left the mine for the day.

Shotfirers should be authorized to refuse to fire any shots that, in their judgment, are unsafe.

QUESTION—*What are the causes of the production of coal dust in mines, and what steps would you take to reduce it as much as possible?*

ANSWER—The production of fine coal dust is most serious in the mining of coal by machines. Large quantities of fine dust are also produced by the excessive use of powder, in blasting a soft friable coal. In the mining of coal by machines, the fine cuttings or "bug dust," as it is called, should be carefully loaded and taken out of the mine in dust-proof cars. No accumulations of these cuttings should be allowed at the working face and they should not be thrown back in the gob.

In respect to blasting a soft friable coal extra care must be used in the placing of the shots and the charging of the holes. All holes should be examined by competent men appointed for that purpose, before the holes are charged or fired. Strict regulations should be enforced and violations of the rules promptly punished.

QUESTION—*What are the chief dangers of coal dust and what steps would you take to counteract them?*

ANSWER—The danger arising from the presence of dust in mines is dependent on the fineness and inflammability of the dust and the manner in which the dust question is handled. The danger is imminent where dust is allowed to accumulate, in quantity, on the roads and timbers of all air-courses, travelingways and working places. Also, when all needed precautions are not taken to prevent the suspension of the dust in the mine air, by humidifying the mine by steam introduced into the intake current, or by spraying or watering the roads and working places. The methods employed in the working of the seam and the mining of the coal are largely responsible for the degree of danger from dust.

QUESTION—*Explain the difference between a force fan and an exhaust fan.*

ANSWER—As far as the fan itself is concerned there is no difference in its action. The revolution of the fan blades develops a centrifugal force by reason of the weight of air revolved within the fan. As a result air is drawn in at the center and discharged at the circumference of the fan. The difference between these two types of fans consists solely in the manner in which the fan is connected with the mine to be ventilated. In a blowing fan the circumference of the fan is connected directly with the fan drift, while the central orifice of the fan is open to the atmosphere. This arrangement permits the air to be drawn in to the fan and discharged into the fan drift by which it is conducted through the mine under the pressure due to the action of the fan.

On the other hand, when the fan is exhausting the central orifice of the fan is connected by a suitable casing with the fan drift, while the circumference of the fan opens into an expanding chimney leading to the atmosphere. By this arrangement the mine air is drawn into the fan and discharged at its circumference into the chimney by which it is thrown into the atmosphere at a low velocity.

In each case the fan acts to produce a depression at its center and a compression of the air at its circumference. When blowing air into the mine the latter is ventilated under a pressure above that of the atmosphere, this pressure being created by the fan is always determined or caused by the mine resistance. When exhausting air from the mine the latter is ventilated under a pressure below that of the atmosphere, the atmospheric pressure then forcing the air through the airways to relieve the depression caused by the fan.

Daily Output of Basic Commodities Higher in February; Retail Sales Keep Pace; Wholesale Price Index Up

Productive activity was maintained in February at the high levels reached during the previous month, according to early figures received by the Department of Commerce through the Bureau of the Census. In many cases declines are shown owing to the smaller number of working days, but when allowance is made for this factor, the rate of production in most of the important basic commodities was slightly larger than in January.

Daily rate of consumption of cotton and of production of fine cotton goods, pig iron, lumber and automobiles exceeded the January rate. In most lines connected with railroad equipment and building, such as locomotives, pig iron, fabricated structural steel, building contracts and oak flooring, the actual February sales were still greater than January orders.

Retail sales kept up to January's mark in spite of the shorter month, while the transportation system showed signs of overcrowding in the large car loadings and increased shortage of freight cars. The wholesale price index advanced one point, and again the decline in coal prices prevented a further rise. Food prices, both at wholesale and retail, declined. Increased prosperity is confirmed by the marked decline in business failures and the continued rise in stock prices.

In the textile field, the increasing rate of cotton consumption reduced total stocks of raw cotton at the end of February to the lowest point reported at this season of the year since 1914. Wool receipts, with one exception, were higher in February than in any month since April, 1921, while silk consumption, also with one exception, was the largest since 1919.

Pig-iron production in February was at a slightly higher rate per day than in January, while steel-ingot production was slightly less. Unfilled orders of the United States Steel Corporation increased to 7,283,989 tons, the highest since January, 1921. Unfilled orders for locomotives made a new high record in February, fabricated structural-steel sales were the highest since last May but orders for steel castings declined.

Production of bituminous coal declined in February to 42,160,000 tons from 50,123,000 tons in January.

Building contracts awarded in February amounted to 41,611,000 sq.ft., showing an increase over January in place of the expected seasonal decline. Shipments of building materials, such as lumber, flooring and cement, showed large increases over January and over February of last year.

A net shortage of 65,000 freight cars at the end of February was the first increase over the recent low point of 45,000 cars short at the end of January.

U. S. Steel Corporation Mines 23,293,471 Tons of Coal in 1922; Wages Fall

The mines of the United States Steel Corporation produced 23,293.471 tons of coal in 1922, as compared with 21,627,939 tons in 1921, an increase of 1,665,532 tons, or 7.7 per cent. Of the tonnage produced in 1922, 16,778,413 tons was used in the manufacture of coke and 6,515,058 tons for steam, gas and all other purposes, as compared with 14,546,103 tons used in the manufacture of coke and 7,081,836 tons used for gas, steam and all other purposes in 1921. Inventory as of Dec. 31, 1922, showed the value of coal, coke and other fuel on hand to be $10,807,030, as compared with $13,054,195 on the corresponding date of the previous year.

There was expended for improvement on the coal and coke properties of the corporation during the past year $5,987,117, of which $1,762,509 was for the acquisition of additional acreage of coking and gas coal in Greene County, Pennsylvania, and in the Illinois and Indiana coal fields. For surface land in Greene County, Pennsylvania, for a shaft and town site at the Dilworth works and for a railroad right of way $171,367 was expended. In the Connellsville district $469,313 was expended for tenement houses and $1,343,828 for facilities to increase the output of Colonial Nos. 1, 3 and 4 works and for underground transportation through Alice Mine to Colonial Dock.

In the West Virginia and Kentucky fields $198,931 was expended for bridges, roads, tenement houses and general construction at works Nos. 30 and 31. On the construction of two new coal-mining plants in Washington County, Pennsylvania, $891,089 was spent.

The corporation had on its payrolls of the coal and coke properties on Dec. 31, 1922, 26,856 persons, an increase of 4,405 over the previous year. Its entire payroll numbers 214,931, as compared with 191,700 in 1921, while the total salaries and wages paid was $322,678,130, as compared with $332,887,505 in 1921, a decrease of $10,209,375. The average earnings per employee per day, including general administrative and selling forces, for 1922 was $4.91 as compared with $5.73 in the previous year, while the average earnings per employee per day in December, 1922, was $5.59 as compard with $4.60 in the corresponding month of 1921.

On Sept. 1, 1922, an increase of about 20 per cent was made in the pay of common labor of the subsidiary companies other than those of the railway companies, the rates for other classes of employees being advanced equitably.

The annual report says that in western Pennsylvania $2,302,503, including the expenditures in Greene County, was spent for opening and developing new coal properties and that further disbursement for the same purposes will be made this year.

Pensions paid to retired employees amounted to $1,266,661 compared with $947,879 disbursed in the preceding year. At the close of the year there were 3,886 names on the pension rolls, a net increase of 449 during the year. Since the inauguration of the pension plan in 1911 an aggregate of $8,095,122 has been paid in pensions. For accident relief $4,170,945 was expended, including accruals not yet actually payable under state compensation laws, compared with $4,409,211 in 1921.

The subsidiary companies of the corporation advanced or lent employees on contracts and mortgages $8,143,005, carrying interest at 5 per cent and payable in installments over a period of years to assist them in acquiring homes under the corporation's home-owning plan. In providing modern sanitary facilities for employees $2,252,975 was spent.

The coal properties owned or leased include 419,286 acres vein area of coking coal, 343,384 acres vein area of steam and gas coal, and 303,097 acres of surface. The corporation has 61 coking plants with 18,532 beehive ovens and 2,992 byproduct ovens. There are 62 coal-mining plants not connected with coke plants and nine coal-washing plants.

The corporation's water-supply plants in the Connellsville coke region have a daily capacity of 18,000,000 gallons, and in addition to furnishing the water necessary in manufacturing coke, serve water to three municipalities.

JOBBERS AND DEALERS in Columbus, Ohio, are discussing a circular letter recently received from the Central Fuel Co., of Cincinnati, which represents the Ford coal-producing company. Among other things in the circular are: "The first and last quotations for March for 1-in. shaker, boom-loaded lump, $4.25. Due to a better car supply and decreased costs we are lowering prices from $4.75 to $4.25. Dealers will always get the benefit of Ford's organization and at a fair price. Good coal for good people at a fair price." Attention is called to the published statement from Henry Ford that when he was asked $4 per ton for coal he closed down his Highland Park plant, contending that the price was too high.

Ford Raises Wages in Pond Creek Mines

A new scale of wages was announced March 20 by the Ford interests, which recently obtained control of the mines of the Pond Creek Coal Co. The new rates are retroactive to March 1. The minimum wage for outside labor is now 75c. an hour. A rate of 95c. an hour has been fixed for skilled inside labor such as that performed by assistant foremen. The rate for motormen, bratticemen, tracklayers, wiremen, pumpers and drivers is now 90c. an hour. Brakemen will be paid at the rate of 85c. an hour. Common unskilled inside labor will be paid 80c. an hour.

An increase also has been announced in the mining rate. Cutters' pay has been increased from 31 to 34c., shooting from 23 to 24c. and loading from $1.15 to $1.20 per car. It also is stated that just as soon as scales can be installed all coal will be weighed. In other words, miners will be paid by the ton instead of by the car. It is stated by officials, however, that the scale weights will figure out about the same as the rate per car for loaders.

It also is announced that in the commissaries of the company all goods will be sold at actual cost, in addition to handling charges. Many articles were already being sold at cost, it is stated.

Interesting Data in Annual Report of West Virginia Department of Mines

There were 888 firms in West Virginia controlling 1,381 producing coal mines, exclusive of small country banks and wagon mines, reporting a total production for the fiscal year of 70,888,203 gross tons, a decrease of 9,873,401 gross tons or 12 per cent, compared with the previous fiscal year, according to the annual report of the State Department of Mines for the twelve months ending June 30, 1922. Coke manufactured was 175,156 net tons, a decrease of 661,572 net tons, or 79 per cent.

The department computes the estimated value of the production of both coal and coke for the fiscal year ending June 30, 1922, to have been as follows.

	Value	Gross Tons
Used at mine for steam and heat	$2,019,362.85	791,907
Sold to local trade and tenants	3,343,004.10	1,310,982
Used in coke ovens at the mines	755,185.05	296,151
Shipped	172,862,365.65	67,789,163
Mined by small country mines	1,785,000.00	700,000
Total produced	$180,764,917.65	70,888,203
Total coal sold	177,990,369.75	69,800,145
Coke sold	1,026,414.16	175,156

PRODUCTION OF COAL IN WEST VIRGINIA, FISCAL YEARS ENDED JUNE 30

(In Gross Tons)

District	1922	1921	Increase	Decrease
Panhandle	3,796,904	4,079,344	.....	282,440
Fairmont	9,625,112	14,666,409	.....	5,041,297
Preston, Barbour	3,066,657	4,917,955	.....	1,851,298
Elk Garden	1,080,042	2,453,986	.....	1,373,944
Mason	48,253	242,480	.....	194,227
Putnam	170,552	260,102	.....	89,550
Kanawha	6,110,150	10,237,876	.....	4,127,726
New River	11,900,162	13,740,070	.....	1,839,908
Logan	13,904,980	10,861,391	3,043,589	.....
Pocahontas	18,354,975	17,449,819	905,156	.....
Mingo	2,130,416	1,152,172	978,244	.....
	70,888,203	80,761,604	.....	9,873,401

It is reported that 3,434 mining machines were in use at 1,028 mines employing 44,070 men and producing 54,459,527 gross tons of coal, which represents 76.8 per cent of the production of the state. In 1897 there were only 16 mines using 55 mining machines and machine-mined coal represented but 5.12 per cent of the production. In 1897 there were 10,971,482 tons of coal produced by the pick-mining method at commercial mines and 13,218 pick miners were employed. In 1922 15,728,676 tons of coal was mined at pick mines. It is estimated that 8,795 acres of coal was mined out and that since 1897 the total acreage exhausted has been 180,227.

The average price received by pick miners throughout the state for run-of-mine coal was 95c., the same as in 1921. The average tonnage produced by each pick miner was 1,111. The average annual wage of pick miners (all pick miners included) was $1,055.45, which was $110.20 less than that of 1921. The average selling price of coal shipped from the mines of the state was $2.55 per gross ton, run of mine, a decrease of $2.10 per ton from the price received the year before. Coke was sold f.o.b. at the ovens during the year at an average price of $5.86 per net ton, which was a decrease from the previous year of $3.72 per ton.

Ford Acquires 120,000 Acres More of Coal Land in Kentucky

Henry Ford purchased 120,000 acres of undeveloped coal land in Kentucky early last week, according to an announcement March 23 from the offices of the Ford Motor Co., Detroit. The property, purchased from the F. S. Peabody interests, of Chicago, is in Bell, Clay, Harlan, Perry and Leslie counties. The purchase price was said to be between $3,000,000 and $4,000,000.

Through his latest purchase Mr. Ford comes into possession of a tract of virgin coal lands with a reserve coal supply of 500,000,000 tons, making 165,000 acres of such land owned by the manufacturer.

From these holdings Mr. Ford hopes that within a year will come sufficient coal to supply all his factories in every part of the country, all factories and mills manufacturing various products for his own concerns, as many of the industries in this district as care to buy coal from him, and have left fuel sufficient to supply a part of the domestic demand of the country.

Mr. Ford, it was announced, will ask all industrial users of his coal to install furnaces that will remove only the gas and similar substances, leaving a fuel unimpaired for domestic purposes. The coal, after this process, would be sold to heat the homes of hundreds of thousands of workers throughout the country. The fuel remaining after the gas had been taken out would be even more valuable for home heating purposes than it was before, it was explained.

The Ford plan will be to supply his own industries first, then the industries of companies that supply the Ford concern with parts or materials, then other companies operating in the Detroit region and lastly the domestic consumer, or home owner.

Mr. Ford, it was explained, recognizes the importance of furnishing coal to the domestic user and in keeping prices for this grade of fuel at a uniform level, but believes that the needs of industry should be met first.

AN ADVISORY COMMITTEE to work with the Federal Fuel Distributor on the matter of co-operative selling of coal has been named by Mr. Wadleigh as follows: George W. Reed, vice-president, Peabody Coal Co.; T. F. Farrell, vice-president, Pocahontas Fuel Co., New York City; W. D. Ord, president, Empire Coal & Coke Co., Landgraff, W. Va.; E. M. Poston, president, N. Y. Coal Co., Columbus, Ohio; F. W. Wilshire, vice-president, Consolidated Coal Co., New York; C. E. Tuttle, president, Tuttle Coal Corporation, New York City; C. E. Bockus, president, Clinchfield Coal Corporation; S. P. Hutchinson, president, Westmoreland Coal Co., Philadelphia; S. L. Yerkes, vice-president, Grider Coal Sales Agency, Brimingham, Ala.; W. M. Puckett, president, Corbin Creek Consolidated Coal Co., Charleston, W. Va.; S. A. Scott, New River Co., McDonald, W. Va.; J. H. Woods, general manager of sales, Pittsburgh Coal Co., and E. L. Douglas, vice-president, First Creek Mining Co., Cincinnati.

ASSEMBLYMAN ESMOND INTRODUCED A BILL (Assembly Print No. 1,841) in the New York State Legislature on March 22 which adds a new section 92 to the General Municipal Law authorizing cities and villages to buy coal and sell it to its citizens.

A MEASURE BY ASSEMBLYMAN VAN WAGENEN (Assembly Print No. 1,855) extends the provisions of the application of Section 78 of the Railroad Law, relative to coal jimmies and caboose cars to July 1, 1924.

National Coal Association Flays Union for Condoning Such Bloody Crimes as Herrin Massacre

In a statement issued last week the National Coal Association flays the United Mine Workers for "condoning" the Herrin massacre and other crimes, closing with this pointed sentence: "Has your union done anything whatsoever in the Herrin case other than to exert all its power and influence to obtain acquittal of every single person indicted?" The statement was a reply to Ellis Searles, editor of the *Mine Workers Journal* and official press agent for the union, who denied he ever had condoned the Herrin massacre.

The association, in its letter to Searles following his denial, says: "It is, after all, of small consequence what your personal views are in this matter. The attitude and conduct of the United Mine Workers, whose publicist you have been, is, however, of the greatest consequence."

The association quotes a local paper of the solidly unionized Williamson County (Illinois) mining field, where the Herrin massacre of June 22, 1922, took place. The paper, in reporting something of the notorious event, in which 22 non-union men were cut and shot to death by a mob after they had surrendered in their besieged strip mine, said this in a style reflecting the public opinion of unionized "bloody Williamson":

> At daybreak the 3,000 armed citizens (surrounding the mine) realizing that the future peace of their county was at stake, formed what has been termed by many one of the neatest columns of troops ever seen in the vicinity, worked their way into the stronghold of the outlaws and captured those that remained alive. Several of those that were taken from the pit alive were taken to the woods near Herrin, where later they were found dead and dying. There were no riots, merely the citizens of the county acting in the only way left them for the safety of their homes. The faces of the men who were killed in the disturbance are horrible sights. Uncouth, as all crooks must be at the beginning, they were doubly unattractive as seen after justice had triumphed and the county had again resumed its normal peacetime behavior.

Proceeding, the association, in excoriating the United Mine Workers, says to Mr. Searles:

"What are the vital elements of this Herrin massacre?

"(1) There had been sedulously instilled into the members of your organization in Herrin the fixed determination that no person not a member of your union, or of a union affiliated with it, should be permitted to mine a ton of coal in Illinois.

"(2) The members of your organization felt themselves a super government authorized and empowered to enforce this denial of the right of any other man to work.

"(3) This super government in the execution of its 'justice,' before bringing the power of its hand and the force of its law to bear, careful in the observance of its own rules, had its district leader Sneed telegraph to its head, your associate, John L. Lewis, to pass on the question whether the workers in the Herrin pit as members of the shovelmen's union were or were not within the ban of this super government as strike breakers.

"(4) Immediately prior to the tragedy your associate, John L. Lewis, International president, telegraphed the fatal words that these men were 'common strike breakers.'

"(5) Your associates in the local organization proceeded in organized, deliberate fashion to accomplish the act of 'justice' upon men who broke its law by working without the sanction of the United Mine Workers of America.

"(6) Since the time the deed was done and the mutilated and insulted bodies of the dead disposed of there has not, as you know, come a single sign of repentance or remorse from your associates in your organization in Herrin. Instead, those who were accused of participation in and responsibility for the occurrence of this execution have been honored. Open satisfaction has been manifested at the vindication of the higher law that no man may work without the permission of your organization. The effort of the state to punish the more immediate participants has been fought by your organization with all its power and might.

"How many of these elements of the Herrin massacre, which are the vital elements to the American people, has your organization, and your paper, as its mouthpiece, denounced?

"Was it such a denunciation to publish in the *United Mine Workers Journal* for July 1, 1922, without a word of disapproval, the statements of Subdistrict President Sneed and District Board Member Willis, in which they sought to shift the responsibility from the murderers to the company which had the temerity to seek to mine coal with members of what Lewis telegraphed Sneed could be treated as 'an outlaw organization,' whose members were to be viewed in the same light as 'any other common strike breakers'? Was it in the interests of law and order for Lewis at that critical moment to send a telegram which carried the word from the highest officer of this super government that these workers of the steam shovelmen's union were under the ban, with all the dread consequences that naturally followed that decision?

"Whenever a strike occurs in territory organized by the United Mine Workers, or in any territory which they are attempting to organize, any miner not a member of the United Mine Workers of America works in a mine under peril of violence. This denial of the right to work is the spirit which flamed up at Herrin.

British Miners Organize as at Herrin

"You doubtless recall an article published conspicuously in the *United Mine Workers Journal* of Feb. 15, 1923, with the following editorial note: 'This article was written by a British miner and tells in a graphic way how the union miners of three districts broke up a nest of "blacklegs" (as British non-unionists are called) who were producing coal while the union men were on strike.' Was it a denunciation of the spirit of Herrin to publish this article describing with evident relish an incipient Herrin in England, where the mine workers organized, as in Herrin, to prevent non-union men from working an outcrop mine, drove them from their work by force and intimidation and committed sabotage and theft?

"To what policy are we to ascribe the fact that in the columns of the *United Mine Workers Journal* we find no mention whatever of the acts of three locals of the United Mine Workers at Cliftonville, W. Va., one month after the Herrin massacre and in emulation of it, in organizing, marching upon and attacking with armed force the Cliftonville mine, where non-union men were employed, this attack resulting in the murder of the sheriff who was attempting to preserve for those workers their right to work? For this conspiracy forty-three members and officers of your union, including Jake Andes, temporary president of Local 1355; Harry Kuhns, secretary of the same local; Antone Salenski, president of the Donahue Local, and Louis Albert, president of the Cedar Grove Local, all at Avella, Pa., have been indicted and either pleaded guilty or were convicted after trial, and sentenced to prison terms. Was it in denunciation of the spirit of Herrin, and was it to promote the interests of law and order and to bring evildoers to justice that your union conducted the defense of these men?

"To what policy are we to ascribe the fact that in the columns of the *United Mine Workers Journal* we find no condemnation whatever of the series of outrages at the Willis Branch mine at Willis Branch, W. Va.? In that case, you will recall, the owner of the mine was willing to employ members of the United Mine Workers of America, pay the union scale of wages and apply the check-off to their pay, but refused to close his mine to non-union workers and to order their pay to be checked off. For this refusal the mine was put under the ban of your organization. It was attacked again and again by armed forces, the workers' community shot up, the stone power house blown up, the headhouse burned, the superintendent's house dynamited, the hoist machinery destroyed, and the tipple burned.

"As a result of these acts of warfare, where the issue was not one of wages, not one of working conditions, not one of whether the members of your organization should be employed, but solely a question of the right to work by miners

not members of your organization, Walter Romine, secretary of your local union, and George Barrett, your international organizer, among others, were tried, convicted and sent to the penitentiary, and David Robb, the financial agent of the union, became a fugitive from justice. Your organization has acknowledged responsibility, after suit, by settling for the damage done.

"And again, to what policy are we to ascribe the silence of the *United Mine Workers Journal* as to innumerable other acts of intimidation and violence the country over which have accompanied attempts to work mines with non-union men in territory organized or attempted to be organized by the United Mine Workers?

"We note in the issue of the *United Mine Workers Journal* of July 1, 1922, describing the details of the Herrin massacre, the following statement: 'The taking of human life through lawless acts cannot and must not be condoned or excused.' But we fail to find therein a single word of denunciation of the organized effort to intimidate those men who were engaged in their right to work. I hope that this editorial was intended to convey something more than a mere regret 'that one of the neatest columns of troops' had committed acts so dastardly as to arouse the public conscience against the principle which the United Mine Workers of America have labored incessantly to enforce, *viz.*, that no man shall work in the mines of the United States who is not a member of their organization.

"Webster in his definition of condone says 'to pardon or forgive, especially *tacitly, by treating the offender as if the offense had not been committed.*' In what way has the United Mine Workers of America treated the local organization in Herrin or its members since the Herrin massacre, other than as if the offense had not been committed? What has the union ever done to discipline this local organization? What has the organization done to assist the Attorney General and authorities of the State of Illinois to bring to justice the men who committed the murders which you denounce? In a mining community completely dominated by your union has it made for justice to have the United Mine Workers put the whole weight of its organization behind the defense of every person indicted? Has your union, in short, done anything whatsoever other than to exert all of its power and influence to obtain the acquittal of every single person indicted for the Herrin murders?"

Federated Engineering Societies to Make Survey of Coal Situation

Cincinnati, March 24.—Still another "careful and painstaking survey of the entire coal situation and especially as it is related to the recent shortage," was started under way at the meeting of the Executive Board of the American Engineering Council of the Federated American Engineering Societies which went into session yesterday at the Ohio Mechanics' Institute in this city.

The plan that was put forth and discussed at its opening meeting would provide for the co-ordination of the federated engineers, the Department of Commerce and the Coal Commission appointed by President Harding with all of the other groups and bodies that are interested in order to prevent duplication and avoid conflict.

During the discussion of this subject a letter from John Hays Hammond, chairman of the Coal Commission, was read and discussed. The prime point brought out in this was that the country at large should be aroused to the necessity of larger storage of domestic coal. The need of greater storage of coal for industrial purposes during the summer months to bring about advantages to the industries also was emphasized.

In drafting the resolution for the survey it was stated that its object would be "to determine the facts relating to engineering, economic and chemical factors involved and their influence upon the coal shortage at the mines and by large and small consumers."

Mortimer E. Cooley, president of the Federation and dean of the School of Engineering of the University of Michigan, was delegated to select the personnel of the committee and will announce their names later. He also will draft the line of procedure that will be followed. Twenty-nine units of the Federation and the Executive Board approved of the action taken and it was stated that $15,000 to $20,000 is available for the survey.

Some of the groups whose help will be enlisted in this work are bituminous and anthracite operators, representatives of the public utilities, equipment manufacturers and railroads.

Bids Submitted for 106,236 Tons of Coal For New York Municipal Departments

Bids for furnishing and delivering about 106,236 net tons of anthracite and bituminous coal to various city departments during the three months ending June 30, 1923, were received by the Board of Purchase of New York City on March 20. The fuel required includes 4,529 tons of screened soft coal, to replace domestic sizes of anthracite.

The specifications for screened soft coal call for the following analysis: Maximum moisture (per cent by weight as delivered), 3 per cent; maximum ash (per cent by weight dry coal), 6.5 per cent; minimum B.t.u. (per pound dry coal), 14,500; maximum volatile combustible matter (per cent by weight dry coal), 27 per cent; maximum sulphur (volatile per cent by weight dry coal), 2 per cent; minimum fusing point of ash, 2,550 deg. F.

The specifications for the semi-bituminous run of mine coal required called for the following analysis: Moisture, 3 per cent.; ash, 9 per cent for run of mine and lump, and 11 per cent for slack; B.t.u., 14,000 for run of mine and lump and 13,600 for slack; volatile combustible matter, 25 per cent; and volatile sulphur, not more than 2 per cent.

For furnishing and delivering 3,020 net tons of run-of-mine soft coal to the piers of the Department of Docks and the Fire Department the bidders were Burns Bros., $7.25, and F. M. A. Leach, $7.43, or at about $4.49 and $4.67 per net ton respectively at the mine.

Under Schedule "G," calling for barge deliveries, the bids on 36,980 tons of buckwheat No. 1 ranged from $5.49 (Steamship Fuel Corporation) to $6.80 (Gavin Rowe) per net ton delivered; on 3,000 tons of buckwheat No. 2, from $4.97 (Steamship Fuel Corporation) to $6.30 (Whitney & Kemmerer) per net ton delivered; on 12,900 net tons of buckwheat No. 3 from $3.26 (Steamship Fuel Corporation) to $4.93 (A. C. Gibson), and on 7,510 tons of soft coal from $5.49 to $7.50 delivered.

The prices submitted on buckwheat No. 1 were on a basis of about $3.17 per net ton at the mine; for buckwheat No. 2, at about $2.65; buckwheat No. 3 at about 94c. and for run of mine bituminous at about $4.75 if brought from central Pennsylvania.

For furnishing and delivering by truck to various points in Manhattan Borough 1,850 net tons of buckwheat No. 2 there were seven bidders ranging from $5.75 per ton by Martin F. Shea to $6.75 by two bidders, Blue Ridge Coal Corporation and Coal Traders, Inc. Three bids were received for furnishing and delivering 1,753 tons of screened soft coal. They were from Martin F. Shea, $11.75; Coal Traders, Inc., $11.50, and W. J. Howe & Co., $12.25. Martin F. Shea submitted a price of $5.37 for furnishing and delivering 3,000 tons of mixed coal (2,000 tons of buckwheat No. 3 and 1,000 tons of bituminous coal) while the Penn Fuel Co. submitted a price of $8.18. There were two other bidders.

There were three bids received for furnishing and delivering 1,433 tons of screened coal in Brooklyn, as follows: Wyoming Valley Coal Co., $7.79; Coal Traders, Inc., $11.50, and Commonwealth Fuel Co., $11.83.

For furnishing and delivering 1,300 tons of run-of-mine semi-bituminous coal to various points in the Borough of Queens the lowest bidder was the Titan Fuel Co. at $6.19 per ton, and the highest was the Wyoming Valley Coal Co., at $7.24.

Bids received for furnishing and delivering 1,800 tons of buckwheat No. 1 by barge and truck to designated points ranged from $6.62 by the Steamship Fuel Co. to $7.67 by Whitney & Kemmerer.

Coal Commission Enlists Services of Other Government Agencies in Investigation of the Industry

By Paul Wooton
Washington Correspondent of *Coal Age*

Evidence of insufficient resort to engineering advice impressed John Hays Hammond on his recent visit to the Alabama coal field. He is of the belief that the situation in Alabama is fairly typical of the entire coal industry. Certain companies, he says, make full use of the best available engineering talent, which, he observes, is one of the reasons for the needlessly wide spread between costs of production at different properties. Not only is the advice of coal-mining engineers needed but there is large opportunity in many coal mines, Mr. Hammond declares, for the profitable employment of mechanical engineers. Many of the problems under ground are mechanical, he pointed out.

In some of the Alabama mines, Mr. Hammond says, serious consideration should be given the relative economies which could be introduced by the improvement of underground haulage, by the sinking of more shafts and by the employment of more cutting machines. These improvements, he admits, involve large initial expense, but he believes they should be considered on the basis of ultimate economy. To save long hauls in metal mines, extra shafts frequently are sunk to great depth. While he realizes that a different problem is involved in coal mines, where the volume of the tonnage is so much greater, he points out that there is a corresponding advantage in that the depth of shafts usually is not great.

Sees Need for Better Engineering

Commissioner Smith also is impressed with the need for better engineering in many coal properties. In an address he delivered last year he discussed some engineering phases of the industry. "What engineering can do for the industry is already known," he said at that time, "for we have today large coal mines well laid out and equipped with modern machinery, which show in actual practice how we can better the business of mining coal. Our chief need in this business, as in some others, is merely to raise the average up to the best. Mines planned by engineers and managed by engineers, with the aid of the coal-consuming public, can come much nearer to giving the mine worker an actual opportunity to work eight hours a day and six days a week. Cheaper coal and larger earnings are two ideals which can be attained by engineering after bargaining has failed utterly. The reform of the coal business must be worked out mostly underground."

The commission, as a part of its efficiency policy, has made the largest possible use of government agencies already at work on the coal problem. The Federal Fuel Distributor, the Bureau of Mines, the Geological Survey, the Bureau of the Census, the Federal Trade Commission, the Interstate Commerce Commission and the Bureau of Internal Revenue all are co-operating to the end of making the commission's investigation accomplish the most good possible with the funds and time at its disposal. The latest development in this line of co-operation is the Public Health Service's assignment of sanitary engineers and physicians to assist in the study of prevailing sanitary conditions in mining towns. A group of these specialists left the first of the week for the field.

Chairman Hammond announced on March 24 that the commission is making a close study of the effects of relationships between the mining companies and the railroads in the anthracite region. He admitted that the commission had conferred with Assistant Attorney General Seymour with regard to the legal phases of the dissolution situation.

So that comparisons can be made of the mining laws of the United States with those of other countries, the International Labor office affiliated with the League of Nations is submitting data to the commission on the mining laws of Europe.

Colonel Edward O'Toole, of the United States Coal & Coke Co., conferred informally with the commission recently and told of conditions in the properties he developed in West Virginia and Kentucky.

Commissioner Wallace, of the Washington Coal Operators' Association, accompanied by Eugene McAuliffe, also conferred with members of the commission. A brief in behalf of the Washington Coal Operators' Association was filed. In it the peculiar position of the industry in the State of Washington is set forth. "A few years ago," says the brief, "all producers of coal within the state were members of the Washington Coal Operators' Association. Finding economic existence impossible under the conditions exacted by the mine workers' union, operators from time to time have withdrawn from the association, establishing a scale of wages below that exacted by the union until today but five producing coal companies remain as subscribers to the operators' association and to the joint wage scale last reaffirmed on Aug. 14, 1922. It is these five companies who still seek to maintain the principle of collective bargaining who now desire to present to the commission the situation which confronts them and the labor in their employ."

Photo Harris & Ewing

WAYNE P. ELLIS

Recently selected as secretary of the Northwest Coal Dock Operators' Association, Mr. Ellis is still serving on the staff of the U. S. Coal Commission as traffic expert.

Coal Commission Takes On Three Engineers

Three engineers have been added to the staff of the Coal Commission. They are Walter M. Dake, Jr., Ellery B. Gordon and H. M. Search. Mr. Dake was born in Nashville and educated at Vanderbilt University. He had extensive metal mining experience in Colorado, Nevada, California, Utah, Oregon, Wyoming and Lower California. For many years, however, he has devoted himself exclusively to executive and engineering work in connection with coal operations, most of which were in Western states.

Mr. Gordon formerly was secretary-manager of the Na-

tional Retail Coal Merchants' Association. During the war he was Assistant Fuel Administrator for the State of New York. During 1916 and 1917 he was with the Federal Trade Commission, having charge of the field work in the Buffalo and the Detroit areas. More recently he has been associated with E. W. Parker on the Anthracite Bureau of Information.

Mr. Search was graduated from Lehigh University in 1915, after having completed the course in civil engineering. He joined the technical staff of the Philadelphia & Reading Coal & Iron Co., where he was engaged until 1917, when he became assistant secretary of the Anthracite Coal Operators' Association. He served with the field artillery during the war. From 1919 to 1921 he was with the Weston Dodson Co. His last connection was with the Coal Service Corporation of New York.

Searles Denies Miners Would Take Wage Cut If Assigned Car Was Abolished

That the United Mine Workers of America will not accept any reduction in the present scale of wages is declared in a letter dated March 21 to the Interstate Commerce Commission signed by Ellis Searles in which he styles himself representative of the International Union. This letter was called forth by a statement on March 2 by J. J. Kintner, an attorney for district 2, in an argument before the commission relative to the abolishing of the assigned car rule, in the course of which he gave the commission to understand that if the commission would abolish the assigned-car rule the bituminous coal miners of the country would be willing to accept a reduction of approximately 20 per cent in their wages.

"As the duly accredited representative of the International Union of the United Mine Workers of America," said Mr. Searles in the letter, "I am authorized and directed by Philip Murray, acting International President of the union, to submit to your honorable body the following statement:

"The International Union of the United Mine Workers of America denies and disavows the statement in question which was made by Attorney Kintner. The International Union was not and is not in any manner responsible for said statement being made to the commission. The International Union here and now declares that it has no purpose or inclination to accept for the coal-mine workers of this country any reduction in wages, neither on account of the assigned-car rule nor any other reason. Any statement to the contrary that is made by any other person must be taken and understood as being an assumption that is not justified nor warranted by the policy of the International Union."

In face of statistics that indicate that the average earnings of miners last year was $700, Mr. Searles said, "it is astounding that any person should even suggest a reduction."

International Railway Fuel Association to Hear Kruttschnitt and Maher

Julius Kruttschnitt, chairman of the executive committee of the Southern Pacific Railroad Co., will deliver the opening address at the convention of the International Railway Fuel Association, at the Hotel Winton, Cleveland, on May 21-24. An address also will be made by T. K. Maher, president of the Maher Collieries Co.

A partial list of the papers to be presented is as follows: "Extension of Locomotive Runs," by C. B. Peck, associate editor, *Railway Age;* "Considerations Covering Use of Oil as a Locomotive Fuel," by M. C. M. Hatch, mechanical engineer, M. K. & T.; "Fuel Saving Aspect of Boiler Water Treatment," by C. R. Knowles, superintendent water service, Illinois Central; "Value of Individual Fuel Performance Records," by L. G. Plant, associate editor *Railway Review;* "Standardization of the Coal Business," by George H. Cushing; "The Other 10 Per Cent," by R. S. Twogood, assistant engineer, Southern Pacific; "Economic Aspects of the Fuel Oil Situation," by C. E. Beecher, U. S. Bureau of Mines; "Economy in the Heating of Stations and Buildings," by Prof. R. W. Noland, Purdue University; "Incentives for Promoting Fuel Economy," by O. S. Beyer, Jr. There also will be a topical discussion of the paper on "The Effect of Tonnage Rating and Speed on Fuel Consumption," presented by J. E. Davenport at the 1922 convention.

Judge McClintic Enjoins Use of Check-Off For Unionization of Open-Shop Mines

Judge George W. McClintic, in the U. S. Court for the southern district of West Virginia, handed down an injunction on March 21 at Huntington under the terms of which twenty companies having an agreement with the union are restrained from paying over to the union any moneys collected through the "check-off." The effect of the decision will be to restrain the use of money derived from the "check-off" for the unionization of open-shop mines.

Judge McClintic's decision was made in connection with a suit instituted several months ago by the Carbon Fuel Co. and twenty-two other coal-mining companies in the Kanawha district against the international organization of the United Mine Workers, its officers and District 17, its officers and local unions, as well as against the Black Betsy Consolidated Coal Co. and twenty other firms or companies now paying the check-off in accordance with an agreement with the union.

One effect of the decision may be to prevent the consummation of a contract now being negotiated with the union covering the year beginning April 1, 1923.

The injunction also prohibits the international organization from sending any money into West Virginia to be used for the unionization of the plaintiff's mines and prohibits the international organization from interfering in any way with the production of coal or with the employees of the plaintiff.

The Black Betsey Consolidated Coal Co. and Edwin Marmet and the nineteen other codefendants are especially enjoined from paying any money to the union for unionization activities against the operations of the plaintiffs. The defendants also are enjoined from doing or causing to be done anything toward the calling or continuance of any strike.

In explaining the effect of the injunction, S. B. Avis, attorney for the plaintiffs, said that "the miner and the operator can get together, but any agreement they may reach cannot be used to force a third party, either miner or operator, to concur in the agreement."

The terms of injunctions granted last summer to the Anchor Coal Co., Dry Branch Coal Co., the Seng Creek Coal Co. and the Raleigh-Wyoming Coal Co. prohibiting trespass and the use of persuasion or violence on employees of the plaintiff are reiterated in the injunction just handed down. Judge McClintic holds that the miners' union is engaged in a conspiracy to restrain trade and production and that such a conspiracy violates the anti-trust laws.

The injunction suit has been pending since last September, when Judge McClintic granted a temporary restraining order which he later extended but allowed to expire before handing down a final decision.

Class 1 Railroads Consume 10,127,000 Tons Of Coal in December at $3.76 per Ton

Class 1 railroads consumed 10,127,000 net tons of coal during December, 1922, as charged to account 394, compared with 9,736,000 tons in November, 1921, according to a report of the Bureau of Statistics of the Interstate Commerce Commission covering 177 steam roads. During the twelve months of 1922 these roads consumed 95,919,000 tons as compared with 91,726,000 tons during 1921. The delivered cost per ton in December was $3.76 or 15c. above that for December, 1921. The per-ton cost for the year was $3.94 as compared with $4.10 during 1921.

Fuel-oil consumption continues to gain. During December 157,380,000 gallons were used, as compared with 126,665,000 gallons in December, 1921. The figures for the twelve months of 1922 and of 1921 were 1,564,872,000 and 1,426,975,000 gallons respectively.

Wages in Harlan Field Not to Be Reduced; Scale Renewed in Western Kentucky

Wages of coal miners in the Harlan field will not be reduced April 1, according to announcement made March 22 following a meeting of the Harlan County Coal Operators' Association. The contract between the miners and operators expires April 1, and it was reported that an effort would be made to reduce wages.

In a statement issued at the close of the meeting E. R. Clayton, secretary of the association, declared that "the coal operators appreciate the fact that the extreme car shortage has worked a hardship on the men as well as on the companies and for this reason they are not going to make any reduction."

The greater portion of the field is non-union, but the non-union sections are affected by the union in that wages usually are based on the rates provided for in the union contract.

The West Kentucky Coal Operators Association and District 19 (Kentucky) of the United Mine Workers of America also have come to a satisfactory agreement for renewal of the old wage scale, which has been in effect for two years. The new agreement starts April 1, for one year, carrying a renewal of the old contract throughout. The conference, which was held at Louisville, was harmonious in every respect.

Harry L. Gandy Named Executive Secretary Of National Coal Association

An executive secretary has been chosen by the National Coal Association in the person of Harry L. Gandy, formerly a Representative in Congress from South Dakota. Mr. Gandy's association with the coal industry dates from 1914, when, on entering Congress, he was made a member of the Public Lands Committee and assigned to a study of the coal-leasing portion of the General Public Land Leasing bill. Since his retirement from the House of Representatives he has been actively engaged in the preliminary financing and other arrangements for the opening of a large coal property in the Huntington canyon of Utah.

Mr. Gandy was born in Churbusco, Ind., in 1881. His higher education was obtained in the Tri-State College at Angola, Ind., from which he was graduated in 1901. Prior to his graduation he had taught school for several terms and followed that profession subsequent to his graduation. He then entered the newspaper field and conducted newspapers at LaGrange and Kendallville, Ind.

Mr. Gandy went to Rapid City, S. D., in 1907 as news editor of the *Daily Journal*. Later he became business manager of the Rapid City Printing Co. and editor of the *Rapid City Guide*. From Jan. 1, 1910, to Aug. 1, 1918, he owned the *Gazette* at Wasta, S. D. In 1910 he was appointed United States Commissioner for the district in which he lived. This post was an important one, due to the large volume of public-land business in that portion of the state. Later he was elected to the State Senate from Pennington County. He is the only Democrat elected from that county to serve in the State Senate either before or since. He served one term and declined renomination. In July, 1913, he was appointed receiver of public moneys in the U. S. Land Office at Rapid City. He served until March 4, 1915, in that capacity.

In 1914 Mr. Gandy was elected to the House of Representatives from the Third South Dakota district. He was reelected in 1916 and 1918, but was carried down to defeat in the Republican landslide of 1920. Even then, however, he ran many thousands of votes ahead of the ticket. He is particularly proud of the fact that during his political experience there was no election in which he did not carry, by a large majority, his home precinct, city and county, each of which ordinarily is overwhelmingly Republican.

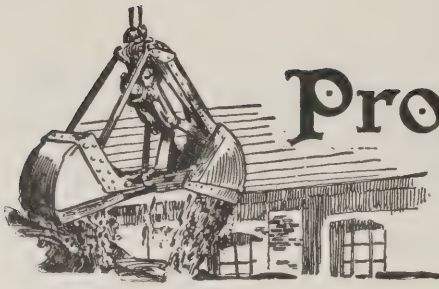
It was Mr. Gandy who held out most determinedly on the House Committee on Public Lands for the provisions in the Leasing Act which allow portions of the revenue derived from mineral leases to go to the state and to the reclamation fund.

Mr. Gandy operates a 2,500-acre grain and livestock ranch near Wasta.

Since leaving Congress Mr. Gandy has been associated with J. H. Mays, formerly a member of the Utah delegation in the House of Rrepresentatives, in arranging the financing of and other preliminaries preparatory to the opening of a large coal property in the Huntington canyon of Utah. The proposition, among other things, requires the financing

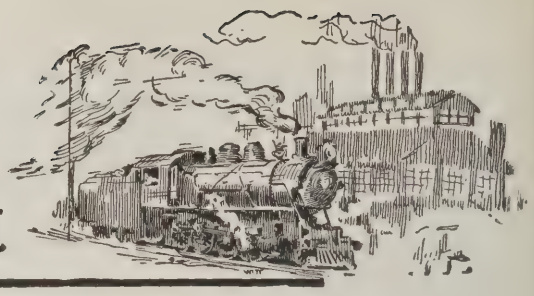
Photo Harris & Ewing

HARRY L. GANDY



of a line of railway. In connection with these negotiations Mr. Gandy came in contact with a number of Eastern coal operators. The opening of his Utah coal operations must await the construction of the railroad, which led to his being asked to accept the executive secretaryship of the National Coal Association.

Brydon Favored for Presidency



There are indications of widespread sentiment in the National Coal Association favoring the selection of John C. Brydon, of the Quemahoning Coal Co., of Somerset County, Pennsylvania, to be the president of the organization during the coming year. Were Alfred M. Ogle not inclined to insist on the continuance of the precedent established by J. G. Bradley—that presidents serve for one term only—it is certain that he would not be opposed. Since the prospects are that he will decline to be a candidate for re-election, many members of the organization, attracted to Mr. Brydon by his accomplishments as chairman of the special committee, will insist on pushing his candidacy.

Directors of the National Coal Association will meet in New York on April 11. In connection with that meeting, W. H. Cunningham, chairman of the convention committee, has asked his committee to meet to discuss the program for the annual meeting in June. The special committee of bituminous operators, of which J. C. Brydon, is chairman, will meet in New York on April 10.

Owing to its crowded docket and the short time remaining in the spring term the U. S. Supreme Court has notified the Federal Trade Commission that it will be unable to hear the Claire Furnace cost-reporting case before the fall term. The appeal from the Court of Appeals of the District of Columbia to the Supreme Court was granted March 17 and the commission sought permission to argue the case before the summer adjournment. The Court of Appeals on Jan. 2 sustained the injunction against the commission in the lower court.

Production and the Market

Weekly Review

The spot market on bituminous coal has sagged to a point where sales are extremely light. Spring weather and the beginnings of improvement in transportation have taken off the last edge in the East. The trade along the Atlantic coast misses the fairly steady inquiry that was current a month ago from retail dealers who were driven to find substitutes for anthracite. Manufacturers also who were then inclined to hedge against a possible upward swing in prices have now about ceased making their small purchases and are much disposed to await developments. There are shippers who figure a largely increased use of steam coal during the coming season based partly on better business generally and increased traffic.

Production was maintained at around the 11,000,000-ton mark while prices generally showed a decline. *Coal Age* Index of spot prices at the mines dropped to 246, a decline of 17 points from last week's figure of 263, with the average price at $2.98.

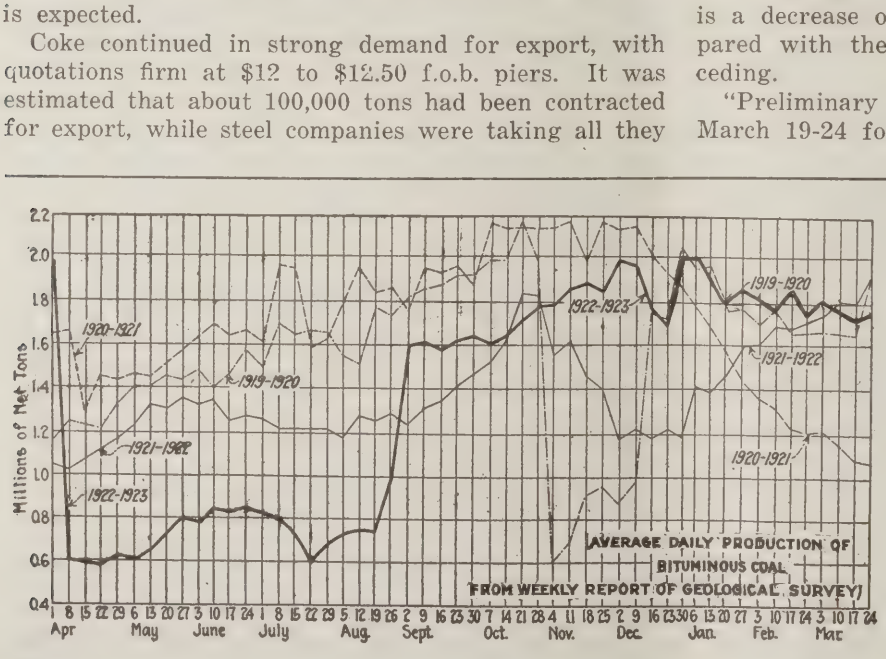
Heavy Demand for Coke for Export

The demand for coal for export quieted down considerably notwithstanding the conflicting reports of labor troubles in the British mines, which were largely discounted by New York houses with British connections. The short flurry because of exaggerated export demand had the temporary effect of increasing output, and there were accumulations at the Hampton Roads piers. Even contract tonnage moved rather slowly coastwise and it was only with difficulty that some shippers were able to arrange for disposition of their April coal. A demand for low-volatile coal for export is expected.

Coke continued in strong demand for export, with quotations firm at $12 to $12.50 f.o.b. piers. It was estimated that about 100,000 tons had been contracted for export, while steel companies were taking all they could get. Water freight rates were high, some owners, it was reported, quoting around $4 for April shipment to west Italy. The current rates to Hamburg range were $3.30 @ $3.50 for coal and around $5.50 for coke.

Dumpings at Hampton Roads for the week ended March 22 were 407,234 net tons, as compared with 344,052 net tons during the previous week.

There was a slight flurry in the Midwest due to a sudden but short-lived cold spell. While the larger industries are displaying little inclination to contract it is expected that considerably more tonnage than normal soon will be covered, principally because purchasing agents are fully awake to the danger of a car shortage during the summer and autumn months.



Better Car Supply at Gateway

From the Cincinnati gateway come reports of better car supply in eastern Kentucky and Logan County, West Virginia, simultaneous with a sharp drop in Eastern demand. Buyers large and small in the inland markets are marking time. The market on lump is gone and the prospects for steam coal after April 1 are dubious.

In New England most of the central Pennsylvania coals are a drug on the market. In a few cases the operators are disturbed over possible labor complications, especially in non-union sections, but the majority have been scaling down prices in the effort to enlarge their market.

"Present estimates of the soft-coal production for the week ended March 17," says the Geological Survey, "indicate a total output of 10,424,000 net tons, including coal shipped, mine fuel, local sales and coal coked. This is a decrease of approximately 200,000 tons as compared with the revised estimates for the week preceding.

"Preliminary reports of cars loaded in the week March 19-24 forecast another week's output at about

10,500,000 tons. Loadings on Monday, March 19, were 39,215 cars and fell on Tuesday to 30,721 cars, and by Thursday had declined to 29,292 cars."

The anthracite situation has eased considerably. Demand is easier and retail dealers have no difficulty in taking care of current needs. Many have discontinued the purchase of independent coal unless they can get it at lower figures than prevailed last week.

Production of coke during the week ended March 17, as reported by the Geological Survey, was 409,000 net tons as compared with 280,530 tons during the previous week.

Demand Sharp in Chicago Flurry

A cold spell early last week brought a sharp but temporary demand for nearly all grades of coal in the Chicago market. Retail dealers showed some anxiety. Car numbers were in demand until the middle of the week, when the market became normal to weak on all steam sizes.

Railroad contract bids are higher in Indiana and West Virginia because of the awakening in export demand.

The situation for domestic coals was easy, but retail dealers everywhere in the midwest territory are slow to stock in spite of the recent reductions all along the line on prepared sizes. The fact that cars have been plentiful throughout the region made it possible for many mines to work four or five days last week, merely supplying immediate demand. Slow steam movement was the principal worry. In the Mt. Olive district most mines have been tied up because of the sluggishness of small sizes. Good Illinois screenings were sold as low as $1.60, though the average was above that figure.

St. Louis Market Brisk Too

The coldest weather of the winter ushered in last week with a temperature of 4 deg. above zero. It found the dealers' yards pretty well loaded and in two days they were cleaned up, principally selling the cheaper grades of Standard and Mt. Olive. For the first time in years the dealers were able to meet an unexpected contingency. This helped to clean up a lot of high-priced coal put in storage several weeks ago. Domestic business for the country was perhaps the most active at any time in the past three months, while country steam was slow.

The terminal situation in St. Louis is bad. The Missouri Pacific, Frisco and Wabash are unable to take care of the

* Net tons, f.o.b. mines. † Advances over previous week shown in **heavy type**, declines in *italics*.

Coal Age Index 246, Week of March 26, 1923. Average spot price for same period $2.98. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the war Industries Board.

tonnage offered and the Terminal Association ties up traffic on the east side. There is no anthracite moving in and very little activity in coke or smokeless.

Screenings Heavy in Northwest

The cold snap caused some suffering in the Northwest. Domestic coals of all sorts sold recklessly. Deliveries were altogether too slow and almost anything burnable was demanded. However, steam coals on the docks moved sluggishly. A price drop of $1 to $1.25 in Youghiogheny and Hocking screenings featured the Head of the Lakes market last week, but despite the off price in screenings, lump and run of pile in Youghiogheny and Hocking remained firm. Lump at Duluth was $8.25@$8.50 and run of pile $7@$7.25. The market was clean of Pocahontas lump and anthracite.

Speculation is rife concerning the probable price of coal after the opening of navigation. It is asserted that bituminous will be at least $1.50 to $2 lower than at present. Bottoms have been chartered to bring up a supply of anthracite as soon as navigation opens, and there has been some chartering for the movement of bituminous. Navigation should open about April 20.

The docks are preparing for a heavy season, providing rates from the mine can be made so as to enable Duluth to compete with the cheaper Illinois coal, which has the advantage now because of the freight rates.

Situation in Milwaukee Nears Normal

The coal situation in the Milwaukee district is rapidly getting back to normal after the worst flurry of the season. Two mid-March blizzards within a week sent people to the yards for fuel of any discription. There was practically no anthracite on hand and not much bituminous or coke were available. The storms seriously impeded rail transportation, but there is considerable coal now coming forward.

Better buying of coal by industrials, byproduct and utility consumers is reported in the Louisville market, and while not much coal is moving to steel industries on open-market orders the steel interests that produce their own coal are not offering it in the open market, which has helped somewhat. General inquiry was better and there was some contract inquiry at prices that seemed attractive. Railroad buying also showed improvement.

L. & N. Issues Shipping Permits

The Louisville & Nashville R.R. has announced that Lake shipping permits are being issued and it is estimated that about 3,500,000 tons will be moved within the next few months. According to a statement issued Kentucky probably will have a larger share of lake business this year than in past seasons. Permits are issued only where the operator has arranged for immediate unloading at lake ports.

Although two snow storms swept down the eastern front of the Rockies the coal trade in that region was not much affected. True, the Kansas City market improved, dealers unloaded a good deal of high-priced coal, and mines picked up in operating time from about 25 per cent to almost 75 per cent. But even that was temporary. In Colorado the new low storage price aimed to stimulate trade has not had the desired effect. About the only mines working anywhere near full time in Colorado are those with railroad contracts. Most lignite operations average three days a week.

Utah business remains unflurried. Lump prices thus far have remained firm but steam coals are difficult to move. Production continues at little better than 50 per cent.

Smokeless Goes All Rail to Milwaukee

Because of the barren condition of the Milwaukee docks some smokeless moved there all rail from the Cincinnati gateway. Lake buyers jumped into the market the early part of the week and filled up with a couple of cargoes for the boats lying at Lake Erie ports, but during the latter part of the week buying was conspicuous by its absence.

The first circular on April prices for smokeless coal shows $6 for lump and egg, $6 for nut and $4.50 for run of mine with no price on screenings. There has been some stocking going on in the smaller towns along the river and some tonnage has been laid away in and around Cincinnati.

Reports from Columbus indicate that prices on contract coal from the Hocking Valley and other Ohio fields probably will range $2.50@$2.75 for mine run although this is not settled. Steam plants have only a fair surplus stock and this is taken as an indication that there will be fair buying later on. Iron and steel plants are buying more actively and orders from utilities are fairly good. The Lake trade is attracting attention.

The Cleveland market has sagged to lower levels, demand has noticeably disappeared and spot prices are lower.

Broadening of the markets for West Virginia smokeless nut and slack coals seems to have been accomplished through buying by some of the steel mills of Pennsylvania and Ohio and quite a large tonnage of this grade of coal it is said, is now being contracted for and shipped.

The Birmingham (Ala.) spot market, while not especially active, is sufficiently strong to move all coal not covered by contract. Bunker coal shipments are fairly good. Production is being maintained at a high level, though car shortage continues bad and is curtailing output to a marked degree.

No Active Buying Foreseen in New England

The trade in New England believes there will be further transportation difficulties. The degree to which this will be felt there naturally will depend upon the volume of coal required, but the outlook is for no such expanded tonnages

as were estimated four and five years ago. Fuel oil has not yet begun to withdraw as an active competitor and last year's experience taught the market that the West Virginia districts, in the absence of any swollen demand overseas, are amply able to take care of this market with only moderate support from central Pennsylvania. Certainly there are no present indications of active buying in this territory.

The contract situation in New England seems to develop very slowly. Aside from factors who have their own wharves there is caution in this respect because of costly experiences at railroad berths during the past season. So much demurrage has been paid that buyers naturally want to make their contracts f.o.b. cars while the agencies are more and more seeking season orders at a fixed price f.o.b. mines plus charges. There is an abundance of shipping and coastwise freights are likely to be on the same moderate basis that prevailed last year. As usual, the great bulk of New England's coal will come forward in steamers, and this situation makes it more and more difficult for the smaller interests to maintain an even flow of coal to New England.

Many Pittsburgh consumers, it is reported, would be glad to make contracts either for short periods or preferably for the coal year to April 1, 1924, but operators have been unwilling to commit themselves. Export demand for gas coal continues heavy.

The outlook in the central Pennsylvania fields is better. Coal operators from that district who have recently visited inland New York and the New England states believe there will be large quantities of coal stored during the summer. Production is increasing.

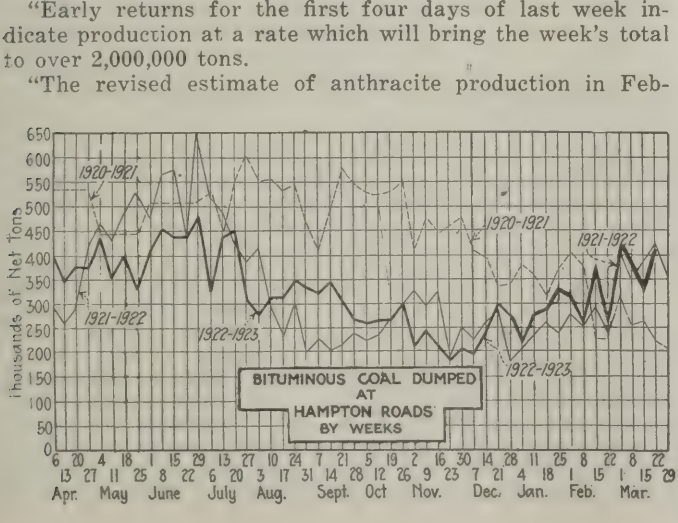
New York Shippers Are Optimistic

Demand at New York was slow but operators and shippers are optimistic, basing their hopes on low stocks all over the country and the opening of Lake navigation.

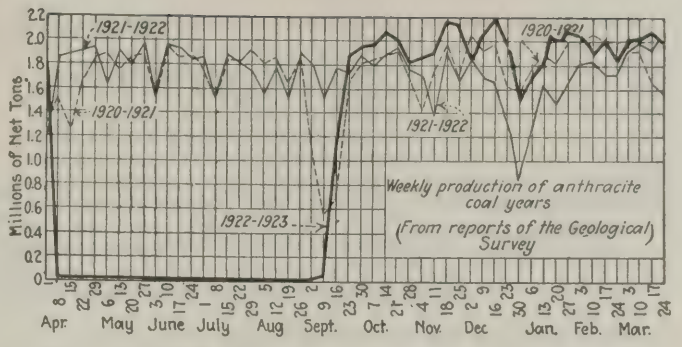
Consumers in and around Philadelphia are buying only to meet immediate needs. It is unusual to see a plant with more than an ordinary supply of coal on hand.

Buying at Buffalo is slow. Prices are low and some believe they cannot go much lower. Continued export demand would, it is believed, improve conditions.

Anthracite Trade Expects Busy Spring



Anthracite producers and retail dealers look for a busy spring and summer. Most yards are without surplus supplies and consumers are anxious, for the most part, to get in their next winter's fuel. Quotations for independent domestic sizes are easier, some retail dealers depending upon the larger companies for most of their tonnage. The steam sizes are moving slowly.



"The production of anthracite in the week ended March 17" says the Geological Survey, "is estimated on the basis of 39,334 cars loaded, at 2,057,000 net tons including mine fuel, local sales and dredge and washery output. This was a slight increase over the week before despite a considerable loss of output on St. Patrick's Day.

"Early returns for the first four days of last week indicate production at a rate which will bring the week's total to over 2,000,000 tons.

"The revised estimate of anthracite production in February, based on final data on shipments in that month, is 7,773,000 net tons, including mine fuel, local sales and dredge and washery output. This amount has been exceeded in only one February (1921) since the beginning of the Geological Survey's record of monthly production,

"The cumulative production of anthracite during the present coal year to the end of February stands at 47,194,000 net tons. This is 41 per cent less than for the corresponding period of the coal year preceding and 44 per cent less than the average for the same period of the past nine coal years."

Kansas Blast Kills 3 and Injures 3

Three men were killed and three were severely injured March 19 in an explosion resulting from an overcharged shot in Thompson, Roberts & Gesslein mine No. 1, Mulberry, Kansas, which the six men were working cooperatively. Thomas Pearson, a veteran miner of the district, who was among those killed, was a candidate in December for secretary-treasurer of District 14, United Mine Workers. More recently he had been considered a possible appointee by Governor Davis to the office of state mine inspector. Richard Medland and Shelton Reeder were the others that were killed. The injured were Dave Curran, Ed Reeder and Loren Reeder. Curran fired the shot.

How the Coal Fields Are Working

Foreign Market And Export News

British Production Finds Ready Market; Railroads Increase Orders

Production of British mines during the week ended March 10 reached 5,713,000 tons according to a cable to *Coal Age*. This is 147,000 tons more than in the preceding week and the largest output of any week of the present year.

The threatened trouble among the mine workers is reported to have been settled by the non-unionists joining the Miners' Federation.

According to a newspaper dispatch an inquiry is to be made into the necessity of establishing a third shift of coal tippers and trimmers in the South Wales exporting district.

The pressure on the Welsh market is becoming heavier. Collieries are very well booked ahead.

The Paris-Lyons-Mediterranean Railway Company has ordered an additional half-million tons for delivery over the remainder of the year. Other French railways are also in the market for several months ahead.

From records of weekly shipments it is noticeable that the pre-war export to South America is rapidly being regained.

There has been no weakening in the north of England market in spite of the increased competition from the U. S. The bulk of the American business has been to Italy.

Coal exports officially reported from London for the weeks ended March 16 and March 23 were, in tons:

	March 16	March 23
Mersey	6,415	7,465
Newcastle (Tyne) district	2,110	9,400
Clyde	....	269

Dumpings at Hampton Roads Increase

Business at Hampton Roads continued on the upward trend last week with prices firm and with a steady increase in dumpings at all piers. During the first eighteen working days of the month a total of 1,020,000 tons had been dumped, with nine more days to go.

Continued movement of coal to Germany and South America was the main feature of the trade, the outlook for improvement in export business being unusually bright. Coal moved in increasing volume to Dutch ports, also.

Domestic trade is falling off substantially, due to the advent of spring. Improvement in the car situation was shown, and was reflected in the increase in stocks at tidewater, 100,000 tons more than at the end of the previous week being on hand at the piers. The tone of the market was strong, and the general feeling highly optimistic.

Switzerland Coal Imports

There were imported into Switzerland during the period Jan. 1 to Feb. 15, this year 203,514 tons of coal, according to statistics given out by the Federal Department of Political Economy at Berne. The coal came from the following countries:

	Tons
Germany without Saar	44,373
Saar District	44,070
France	67,354
Belgium	47,717

The imports from Germany without Saar during the first half of February consisted of 2,300 tons of bituminous coal, 4,700 tons of coke and 2,700 tons of briquets.

News Items From Field and Trade

ALABAMA

The Munro-Warrior Coal Co., Birmingham, is reported to have acquired the No. 2 mine of the Black Creek Coal Co. at Nauvoo, Walker County, and it is understood will build new tipple, washer, etc., and electrify the mine. The property embraces a large tract of Black Creek coal, which is one of the best domestic fuels on the market.

The Kewanee Coal Co., Jasper, has acquired the properties of the Smith-Duffee Coal Co. and contemplates the operation of two or three new mines.

The Brilliant Coal Co., Birmingham, with operations at Brilliant, Marion County, it is reported, is considering the erection of a new washer, tipple and power house at its mines and the purchase of electrical equipment to be used in the operation of its No. 5 and No. 7 mines. These openings are on the Brilliant Black Creek seam of coal, which is a high grade domestic fuel and it is understood the holdings comprise about 8,000 acres.

Charles M. Sartain, F. M. Sartain and Frank Boyer have incorporated the **Sartain-Boyer Coal Co.** at Jasper, with a capital of $150,000.

The Alco Coal Co. has been incorporated at Tuscaloosa, with J. D. Henderson, Fleetwood Rice and Hunter M. Smith as incorporators and with a capital stock of $20,000.

COLORADO

The Colorado Fuel & Iron Co., at the annual stockholders' meeting held March 19 in the company's office in Denver, **with one exception re-elected the old Board of Directors.** Arthur Woods, of New York, was chosen in the place formerly held by Raymond B. Fosdick. The following now comprise the board: George B. Berger, William V. Hodges, S. G. Pierson, J. F. Welborn, Fred Farrar, John C. Mitchell, and Albert A. Reed, of Denver; E. H. Weitzel and M. D. Thatcher, of Pueblo; A. L. Boulware, J. H. McClement, Arthur Woods, and Kingdon Gould, of New York. Following the approving of the report of the officers and the adjournment of the stockholders' meeting the directors re-elected the following officers: J. F. Welborn, president; Fred Farrar, executive vice-president; S. G. Pierson, E. H. Weitzel, Arthur Woods, A. H. Lichty, vice-presidents; Fred Farrar, secretary. Other officials of the company are: R. L. Hearon, traffic manager; Thomas Aurelius, manager of sales; A. W. Sampson, general auditor; J. B. Marks, purchasing agent; F. H. Bentley, statistiican; P. A. Weiting, asst. treasurer; P. E. Thatcher, cashier; Fred Farrar, general counsel; Wendell Stephens, attorney; E. V. Cary, L. B. Rogers, assistant secretaries; F. E. Parks, manager steel mills; D. A. Stout, manager fuel department; L. B. Weed, general superintendent iron mines and quarries; E. H. Weitzel, general manager.

W. D. McCausland, general manager of the Leyden Coal Co., has engaged James Virgin for superintendent of the Leyden mine, near Denver. Mr. Virgin hails from Johnstown, Pa. He had been employed for seven years by Mr. McCausland, when the latter was operating mines in Pennsylvania and West Virginia. **J. E. McLaughlin** has been appointed mine foreman.

Prairie Canon Mine, of the Prairie Canon Coal Co., Vallorso, located in Las Animas County, on the C. & S. R.R., which closed in September, 1921, was reopened in May, 1922.

Sante Fe Mine, of the Sante Fe Coal Co., Denver, located in the Las Animas County, on the A. T. & S. F. R.R., which closed in February, 1921, was reopened in June, 1922.

The Young Mine; Young & Caddell, of Denver, operators; located in Las Animas County, on the D. & R. G. W. R.R., a new mine, was opened in December, 1922.

Piston Mine, Colorado Fuel & Iron Co., Pueblo, located in Huerfano County, on the D. & R. G. W. R R., which closed in December, 1921, was reopened in August, 1922.

Kebler No. 1 Mine, of the Colorado Fuel & Iron Co., Pueblo, located in Huerfano County, on the D. & R. G. W. R.R., which closed in December, 1921, was reopened in August, 1922.

Sunnyside Mine, of the Sunnyside Coal Mining Co., Denver, located in Huerfano County, on the D. & R. G. W. R.R., which closed in November, 1921, was reopened in June, 1922.

ILLINOIS

Work on the **proposed mine of the Illinois Coal Corporation**, which will be sunk in Elk Prairie township, in Jefferson County, is scheduled to begin late in March. The company owns several thousand acres of coal lands in Jefferson County, and it is said the mine will be one of the largest producers in the country.

According to an announcement made at the office of the superintendent of the St. Louis division of the Illinois Central R.R., **construction work on the cut-off from Edgewood, Ill., to Fulton, Ky., will be under way within 10 days.** Work will be started all along the route, according to the announcement, in spite of any action which has been started or may be begun to prevent the construction of the line.

The Harrisburg Fuel Co., Ledford, Saline County, have reopened their mine, closed in April, 1921, located on the Big Four. This company has another mine at Harrisburg.

The Saline Gas Coal Co., at Harrisburg, Saline County, **has opened a new mine** on the Big Four. This company has another mine at Ledford.

William Van Hoose, of Cambria, Williamson County, **has opened a new mine** at that place.

The Franklin Coal & Coke Co., at Royalton, Franklin County, **has reopened mine No. 2**, on the Missouri, Pacific and the C. B. & Q. Rys., closed in May, 1921. The company has two other mines, located at Royalton.

Five of the Old Ben collieries located in Franklin and Williamson counties have been closed indefinitely. While the lack of any market for the coal produced by these mines is given as the primary reason for the indefinite suspension of work, it is also the intention of the company, according to reports, to make some needed repairs and improvements during the suspension. The mines affected are No. 14, at Buckner; No. 15, at Pershing; No. 16, at Rend; No. 17, at Rendville, all in Franklin County, and No. 20, at Johnston City, in Williamson County. At the Buckner mine it is also announced that a considerable amount of work will be done on the shaft, which will be concreted. At Pershing operations will be resumed as soon as a new sizing plant can be installed, and other improvements made which will facilitate greater production.

The Southern Mining Co. has purchased a tract of 555 acres near and to the east of the town of Hegeler, a village in the Danville mining district. The tract is underlaid with coal.

The Rex Coal Mining Co. has reached coal at a depth of 154 ft. on its 600-acre lease near Warner. The vein has a thickness of 4 ft. 8 in. This is the third vein. The first vein, 26 in. thick, was found at a depth of 35 ft., and the second vein, of 14 in., at 95 ft., neither of which will be worked. The company is incorporated for $20,000. Harry E. Bishop is the president; Clarence Hintz, vice-president, and Charles W. Krueger, secretary and treasurer.

The top works of **Wasson No. 1 mine**, near Harrisburg, are to be rebuilt at once.

Railroads operating in the Franklin and Williamson County fields have abolished the position of car distributor because of low business. During the car shortage in the fall and early winter the railroads jointly employed a car distributor apportioning cars to 60 mines.

The **C. B. & Q. R.R.** is doing the preliminary work toward the construction of a double track between Waltonville and Woodlawn. It is said the company is **planning to double track its system in the coal fields.** The **Illinois Central** plans to construct a line from Zeigler, in Franklin county, to a point in Saline county, to connect with the Edgewood-Metropolis cut-off. Articles of incorporation have been filed by the road for the construction of this branch, which will be known as the **Zeigler Junction & Southwestern R.R.**

Mine No. 5 of the Spring Valley Coal Co., located at Spring Valley, will be **closed for an indefinite period.** During the suspension the main shaft will be repaired and other improvements be made around the top works of the plant.

The **first death from the gas explosion in the De Koven mine** of the Madison Coal Corporation, Feb. 24, has occurred. Elmer Scott, 42, a Central City miner, died in Paducah, March 17. He was one of an inspection party caught by a fire caused by a miner lighting a carbide lamp contrary to orders.

Work of **re-equipping the old Milligan mine at Pinckneyville** is under way and coal will be produced at the shaft before many weeks. The mine has not been operated for some time. A switch is now being constructed from the St. Louis division of the Illinois Central R.R. to the mine. The work is being backed and supervised by William A. Lafont, of Pinckneyville, formerly connected with the firm of Dowell & Lafont, of Duquoin.

The **Suburban Coal Co.** of Belleville, is the name of a new concern just formed at that place. The new company has been capitalized at $50,000 and owns properties valued at $30,000. The stockholders are John Henderson, V. M. Henderson, Theodore Michaelis and Louise E. Michaelis. John Henderson, who is from St. Louis, has been at the head of the West Virginia Coal Co., of that city, for years.

The **St. Clair mine at Freeburg**, owned by the General Coal & Mining Co., which was closed down some time ago when the company failed to meet a payroll, **has resumed operations** in full. The mine has been purchased by S. J. Fowler, of East St. Louis, and the name of the company has been changed to the **Free-Belle Mining Co.**

A strip mine near Edgemont owned by the Signal Point Coal & Coke Co., a concern recently organized by Julius C. Miller, of St. Louis, **caved in recently** when operations cut too deeply under the foot of a hill. Jones Brothers, a jobbing concern in St. Louis, selling under the name of the Interstate Fuel Co., are trying in the courts to get an adjustment of their relations with Miller.

The Old Ben Coal Corporation will move its offices from the McCormick Building to the 18th floor of the new Illinois Merchants' Bank Building, corner of Jackson Boulevard and South Clark Street, Chicago, upon completion of the building, which is expected to be ready to receive occupants about March 1.

The M. & B. Coal Co., Danville, **has been incorporated** with a capital of $25,000 by L. T. Mauck, William Mauck, Louis Bock and Paul F. Boch.

The Schuline Mining Co., which recently sank a mine on the J. M. Weir farm, near Sparta, has begun drilling again with the intention of going to the second vein of coal about 110 feet below the surface. The first vein varies in thickness from five inches to five feet, the coal lying in a roll.

The Sackville & Wynn mine at Coal Valley, near Moline, **was closed March 9** for an indefinite period, throwing fifty miners out of work.

The mine at Rutland has been sold by court sale at Ottawa for $16,000. It is said that it was purchased by a group of men including Lee O'Neil Browne, J. L. Bane, former State Senator Cullen and others.

The Glenn Coal Co., of Astoria, has filed articles of incorporation, showing a capitalization of $20,000. The company will mine and deal in coal. The incorporators are E. G. Bader, M. W. Hughes and David E. Thomas.

T. J. O'Gara is disposing of his interest in the **O'Gara Coal Co.**, which operates nine mines in Saline County. Benjamin V. Becker retires with Mr. O'Gara from the board of directors. **Frank H. Woods** remains president, an office he has held since the company was reorganized after bankruptcy several years ago, and **F. A. Manly** continues as vice-president and general manager. Negotiations leading up to the acquiring of the O'Gara holdings in the company by the Woods interests through a New York banking syndicate have been in process for some time.

W. G. Maguire, new president of the St. Louis Coke & Chemical Co., a $17,000,000 corporation, is but 37 years old. His concern is now doing, at its Granite City plant east of St. Louis, a thing that used to be considered commercially impossible—it is coking southern Illinois coal at the rate of about 1,000,000 tons a year.

R. H. Beaumont Co., Philadelphia, announces the appointment of **P. K. Reed as manager of the company's Chicago office**, 760 Monadnock Block.

Plans are being made for the establishment of a mine-rescue and first-aid station at West Frankfort, where 4,000 miners are employed.

Lack of orders caused the **Brewerton No. 2 mine at Lincoln to close down.** This is the largest mine in Lincoln and employs about 300 men. It has an output of slightly over 1,200 tons daily. Its tonnage is handled by the Chicago & Alton R.R. It is also stated that the Riverside mine at Petersburg will soon close.

On the ground that the **Star Coal & Mining Co.,** of Belleville, is insolvent, **D. S. Gent, of Chicago, filed** in the St. Clair County Circuit Court, **a petition for the appointment of a receiver** to take charge of the affairs of the company, of which Anthony F. Jakoubek is president. **Judge George A. Crow appointed Mr. Gent receiver.** Loans totaling $31,830.05, made by Gent as trustee, Feb. 25, 1922, are due and unpaid, according to the petition. The defendants named are the Star Coal & Mining Co., Herman Neff, John Isselhard and F. A. Classen, the three latter having been securities on the notes.

INDIANA

There was a **reduction in the number of miner applicants for certificates and permits in Vigo County** at the March session of the County Board of Mine Examiners. Only 55 certificates and 46 permits were issued, which is **about one-third of the number awarded in February.**

Miners of District No. 11, U.M.W.A., will **seek representation in the Indiana State Federation of Labor** and are planning to nominate a candidate for one of the executive offices. William Schmidt of West Terre Haute is expected to be their candidate.

"If a coal company owning several mines were allowed during a car shortage to receive its combined allotment day by day at one or two mines an enormous saving would result," William M. Zeller, sales manager for the Knox Consolidated Coal Co. told the Indianapolis Rotary Club recently at a dinner. "Under those conditions our company **would close down the higher-cost mines,**" said he, "reducing operating expense so that we could pass on this reduction to coal buyers."

The Columbus Mining Co. expects to expend more than a half million dollars in development of a large area of recently acquired coal land in Indiana and extensive improvements on mine properties in that state and eastern Kentucky. Allen & Garcia, well-known mining engineers, have been placed in charge of the work. A syndicate headed by H. A. Requa, J. B. Hilton and A. L. Allais has acquired what is declared to be 2,500 acres of rich coal land in Gibson County, Indiana, and the Columbus company will develop that field. The company officials have announced that new shaker screens and picking tables at the Shamrock mine at Reilly and the construction of a huge conveyor up the side of the mountains in the Hazard field in eastern Kentucky are among the improvements contemplated. The tipple of Mine No. 5 in eastern Kentucky will be remodeled and shaker screens and picking tables installed.

The General Fuel Corporation of Terre Haute has filed a notice with the Secretary of State showing **an increase of $400,000 in capital stock.** The total capital stock of the company is $2,400,000. The company is opening some mines in the Gibson county coal field. All officials of the company are Terre Haute men. John T. Beasley is president; C. J. Richards, vice-president and general manager; John Hoke Beasley, secretary, and Frank W. Richards, treasurer.

The right of Indiana coal operators to demand the use of permissible powder in their mines was again questioned this month by a strike of about 800 miners at the American No. 1 Mine, near Bicknell. **After a strike of about 20 days the miners returned to work** when the officials of the company stood firm on their right to use permissibles not only because they are safer and had been recommended by the inspection bureau following an explosion Jan. 12, but also because of a joint agreement of miners and operators made in 1915.

A joint conference of members of the executive boards of District No. 11, U. M. W., and the Indiana Bituminous Coal Operators' Association which met in Terre Haute on March 20, **reached a satisfactory agreement concerning the hauling of miners to and from their work in the mines. According to the agreement reached by the joint conference the miners are to be hauled between their work** and the cage by the mine motormen where such action is warranted. The motormen are to receive additional compensation for the extra work.

KENTUCKY

The Big Sandy field of the Northeast Kentucky Coal Association will be a beehive of progressive work for the next few years, according to recent announcements. A number of contractors have made **estimates for bids on several new tracks** and new track scales for the river yards at Ashland. The improvement will be made as soon as possible and will be a great aid in expediting the movement of tonnage west bound. Extensive improvements in trackage facilities will be made over the entire Big Sandy division of the Chesapeake & Ohio Ry. in order to enable them to meet the great demand for the special purpose quality coals of this field which is exceeding by far the expectations of the most optimistic interests.

The Humyar Coal Co. of Lennut, has announced that it will erect a clubhouse and Y.M.C.A. building.

The 1922 coal output of Pike County was a little more than 6,000,000 tons, according to the report of Grant Phillips, inspector for the eighth district. The average days worked by the 84 mines was 161. Fifty-nine mines are electrically equipped and 25 are pick mines. Of the 7,499 men employed, 1,521 are outside men and 5,978 are employed inside.

The proposed branch of the Illinois Central R.R., from Central City to Madisonville, will tap into about 20 large coal mines, now served only by the Louisville & Nashville R.R., while there have been some big deals on coal lands which can be reached by this new line.

The Pond Creek Coal Co. has declared a final dividend of $10 a share in liquidation, payable April 2 upon delivery of certificates to the First National Bank of Boston, or to the Chase National Bank of New York.

MISSOURI

The steady conversion of Southwestern railroads from coal to oil for fuel is cutting deeper into the business of the southwestern coal fields. The Cotton Belt is changing to oil for its lines south of Pine Bluff, Mo.; the Frisco railroad for its divisions in the Tulsa (Okla.) region and the Rock Island for its Louisiana division in southern Arkansas and Louisiana.

Walter A. Zelnicker Supply Co. removed March 1 from 325 Locust Street to new offices in the Chamber of Commerce Building, 511 Locust St., St. Louis.

Mine No. 2, south of Macon, which has been idle since Jan. 22, **has reorganized and started to work.** The mine is leased from the **Home Coal Co.,** by a co-operative organization consisting principally of employees.

Missouri **coal interests were glad to see fail in the state legislature a bill aimed at chain stores.** It would have limited anyone person or corporation to a maximum of 10 places of business within the state.

Walter W. Graham, formerly superintendent of the American Sale & Coal Co., of Kansas, is now general manager and superintendent of the Mosby Coal Co. of Excelsior Springs.

The Blackfoot coal mine, located about four miles north of Columbia, **has been shut down** on account of fire which destroyed the fan and motor and house which contains the fan. The damage to the mine itself was estimated at only $300.

NEVADA

The **discovery of a 5-ft. coal vein** in the hills east of Wells is reported. The discoverer, Martin Elorga, is attempting to obtain funds to finance the exploration and development of the deposit.

NEW YORK

William B. Simmons, for several years connected with the business department of *Coal Age* and more recently assistant to A. S. Learoyd, District Fuel Administrator for Greater New York and Long Island, is now associated with Sidford & Greene, 17 Battery Place, New York City.

Rembrandt Peale, Jr., vice-president of Peale, Peacock & Kerr, 1 Broadway, New York City, **is sailing this week for Europe.** He will spend several months abroad studying industrial conditions and the market for coal in England and on the Continent.

The following **bids to furnish 45,000 tons of three-quarter slack coal** to the Buffalo waterworks will show what shippers think of the coming bituminous market: Valley Camp Coal Co., Cleveland ($2.39 freight rate), $2.50; McVicker Coal Co., Cleveland ($2.39 rate), $2.25; Weaver Coal Co., ($2.09 rate), $3.15; Carson & Co., Philadelphia ($2.09 rate), $2.75; Barnett Coal & Coke Co. ($2.24 rate), $2.39; Link-On Coal Corp. ($2.24 rate), $2.50; Lake Erie Coal Co., Cleveland ($2.24 rate), $2.45; E. L. Hedstrom ($2.24 rate), $2.25. The Hedstrom bid, which is lowest, was received 13 minutes after the time fixed for closing. It is the impression that all bids will be rejected, as they were last year.

OHIO

The Big Six Coal Co., Cadiz, has been chartered with a capital of $500,000 to mine coal and to do a general shipping business. Incorporators are R. H. Anderson, W. C. Clifford, O. H. Finical, J. W. Freshwater and Charles W. Wenner.

The Green Coal Co., Cadiz, has been incorporatted with a capital of $25,000 to mine and sell coal in the eastern Ohio field. Incorporators are Helen Sharon, J. M. Sharon, J. P. Liggett, O. S. Cramblet and B. E. Blackford.

The City Board of Purchase of Columbus has been authorized by the City Council **to purchase 12,000 tons of nut, pea and slack** for the municipal light plant, garbage-reduction plant and other city departments. Advertisements for bids for this coal will be put into the local papers soon.

The Red Bird mine, near Pomeroy, was closed on March 17 because of the lack of miners to operate it. Eighteen miners are in jail on a charge of making moonshine. The miners are alleged to have walled up a section of an abandoned mine with fallen slate and equipped it to manufacture liquor on a large scale. They left a hole for an exit in case of a raid. When half a dozen officers crawled into the mine and, unnoticed, removed enough of the slate wall to admit them, they say they found three stills in operation. The first of the miners to reach the exit hole was so fat that he stuck in the hole long enough for the officers to capture him and those behind.

The Blanchard Coal Co., of Zanesville, **has started to place equipment** at Ellis on the Muskingum River, near Zanesville, where it will develop the 2,500 acres of coal land it recently purchased in that vicinity. This is to be one of the largest stripping propositions in the country, officials of the company have announced.

Tedrow Bros., coal operators of Crooksville, have obtained a lease on a tract of approximately 300 acres of coal land near McLuney which will be developed at once. It is planned to open a mine with an output of at least 500 tons from the start. Electrical machinery will be installed.

OKLAHOMA

The interest of the City of Sapulpa in the Sapulpa Fuel Co. has been sold by the commissioners of that city to the Bartlett Fuel Co. of Sapulpa, for $85,000.

PENNSYLVANIA

The first twenty of 1,000 steel coal cars of the latest type for the Pennsylvania Coal & Coke Corporation **have been delivered** and thirty more are almost ready for delivery. The company will spend approximately $2,000,000 on new equipment. The company also will erect repair shops in the district, but the location has not been definitely decided upon. The corporation owns 8,031 vein acres of coal land in central Pennsylvania and has under lease approximately 36,343 vein acres, with a coal reserve sufficient to keep the company operating to capacity for sixty years or more.

Under the provisions of a bill introduced in the Legislature at Harrisburg by Representative Walter W. Kohler, Lackawanna County, it will be unlawful to convey any illuminating gas through pipes or conduits extending through or over ground under which mining operations have heretofore or are now being prosecuted.

The Denver Rock Drill Manufacturing Co., of Denver, Colo., has opened additional branch offices in Pittsburgh and Pottsville, as well as in St. Louis, Mo. The company also announces that Andrews & George Co., Tokio, is its sole agent in Japan.

A movement has been launched among mining men of the Clearfield district looking to the **establishment of a mining institute** for the purpose of having all the mining men embraced within the territory bounded by Grampian, Snow Shoe, Janesville and McCartney meet at least once annually to discuss the problems encountered in mining, and disseminating information.

Members of the United Mine Workers held a mass meeting in Houtzdale on Sunday, March 18, to consider the situation and attempt to enlist the co-operation of the striking miners of the Berwind-White Coal Mining Co. at Windber for their fellow craftsmen at the company's mines in the Houtzdale region. James Gibson, of the Windber local, spoke, and President John Brophy of District No. 2 and others urged the union men to attempt to influence the Berwind-White miners at Houtzdale to join the union.

Representative Richard D. Burns, Philadelphia, sponsor of a resolution calling upon the Governor to create a permanent Fuel Commission, on March 5 **introduced a bill in the State Legislature amending the Public Service Company Act** of 1913, to provide that in addition to the public utilities now coming under the jurisdiction of the Public Service Commission shall be added coal corporations, coal-producing corporations, coal-selling and coal-distributing corporations. The Burns bill provides that the coal corporations be "declared to be public service or utilities companies within the laws of this Commonwealth." A joint resolution was introduced at the same session of the House by David Fowler, of Lackawanna county, **creating a legislative committee to investigate the coal-supply situation**, defining its powers and duties and making an appropriation of $5,000.

One hundred members attended the March meeting of the Pennsylvania Miners' Institute in Johnstown last week and heard a lengthy discussion on the reliability, safety and illumination of electric cap lamps. Twenty-five new members were admitted. Joseph J. Walsh, the state's chief mining inspector, and Rush N. Hosler, chief of the Pennsylvania coal-mine rating bureau, will be present and address the April meeting.

A meeting of the representatives of 40,000 miners in District No. 2, United Mine Workers of America, has been called for April 18 at Dubois. As the scale and other matters have been adjusted for the year, matters of importance only to the organization will come before the convention, although it was not given out in the call just what would be considered.

Two miners, Ora Clevenger of Houstontown and Samuel Gibson of Ralphton, **were instantly killed in an explosion** on March 17 in No. 4 mine of the Quemahoning Coal Co., at Ralphton. The cause of the explosion has not been determined. There were no other men at work in the vicinity at the time.

A new method of solving the mine-cave problem in the anthracite district is provided for in a bill introduced in the House by Representative Walter W. Kohler, Lackawanna County. The measure authorizes the county commissioners to levy a special tax on coal lands each year after first having made an estimate of the moneys necessary to provide 100 per cent reparation in cases of damage by surface subsidence due to mine caves. A special fund for this tax is created and it would be handled by the county commissioners, the county treasurer and the county controller. The provisions of the bill state that within two years after the measure becomes a law the commissioners are to make an estimate of the total amount of money needed to met a situation that may develop with the exhaustion of the coal supply. Following this the special tax would be levied on all coal in place. This would be made annually and be in addition to the county tax on coal lands.

The House of Representatives at Harrisburg on March 19 **passed the Folwer bill repealing the antharcite coal tax** of 1921 by a vote of 147 to 52. Representative David Fowler, Lackawanna, sponsor of the bill, said it had been amended so that it would not apply until Jan. 1, 1925, and that by that time the Commonwealth would have some financial plan that would not need a tax from hard-coal consumers.

The Burns bill, which gives the Public Service Commission jurisdiction over coal companies, making them public utilities, was **recommitted by the House on** March 19 for a hearing. This will be held March 28.

Representative John E. Stavitski, Luzerne County, **offered a series of three bills** March 20 relative to anthracite mining and miners. One of these measures is for the protection of anthracite coal miners in the **determination of the amount of coal to be used as a basis for calculating compensation** for miners and authorizing the miners to employ a check weighman. **A miners' reserve fund is created by another of the measures.** This bill provides that all coal that has been mined and which is not included in the weights allowed or credited to the miners shall be collected and weighed separately. The amount for which the operators would be liable for the mining of this coal, computed at the current rate of compensation, is to be paid into the fund which is to be used for the benefit of the employees injured in the mines or suffering from disease contracted in the mines or affected by old age. The third bill amends an act of 1891 and its supplements by repealing a provision that relates to certain exceptions in which operators of collieries need not keep at the mine a motor ambulance.

The Mattes mine-cave bills, introduced in the House at Harrisburg March 14 by David Fowler, Lackawanna, were referred March 19 by Speaker Goodnough to the House Committee on Ways and Means. Companion bills introduced in the Senate by Senator Davis, Lackawanna, were sent to the Mines and Mining Committee of which Senator Davis is chairman.

J. R. Robinson, ventilating engineer, 627 Wabash Building, Pittsburgh, on April 1 will sever his connection with the Robinson Ventilating Co., and will give his entire attention to the ventilation of mines. He will open an office at 627 Wabash Building, Pittsburgh.

T. D. Williams, of Johnstown, mine inspector for the Sixth Bituminous district, reports **3,874,786 tons of coal mined** in that district during 1922. Of this tonnage Cambria County mines produced 3,304,786 tons and Somerset County mines produced 570,154 tons.

UTAH

All efforts to abolish or restrict the powers or activities of the Public Utilities Commission—and they were many during the two months' session of the late Legislature—failed. At the close of the session President Thomas E. McKay, a Huntsville resident, who has presided over the Senate twice now, was appointed a member of the commission.

WEST VIRGINIA

Charles K. Francis and Harry M. Mohler, investigators representing the U. S. Coal Commission, **were in northern West Virginia inspecting mines about the middle of March.** Such an inspection is being made with a view to submitting a report on the efficiency of mining methods in northern West Virginia. The inspection is being made solely with reference to the physical aspects of mining and the investigators are not concerning themselves with the financial end of the industry at this time. Among other mines visited was one of the Hudson Coal Co. in Harrison County which is operated on a non-union basis. Mines of the Hutchinson Coal Co. also were visited by the federal investigators.

A bill introduced in the West Virginia House of Delegates by Representative Estep of Logan County and in the Senate by Senator McClaren of McDowell County, upon request **would make voluntary associations suable.** It simply provides that any voluntary association of seven or more members may sue and be sued in the name of the association and that service of process upon any officer, manager or business agent of such association shall constitute service upon the association.

The proposal to create a school of mines in West Virginia is incorporated in Senate Bill No. 348, introduced by Senator A. L. Helmick of Tucker County, who is engaged in the mining business. The bill prescribes that the West Virginia School of Mines shall contain departments of mining engineering, mining extension, mining geology and chemical engineering as well as the mining experiment station already authorized under existing law. The departments of mining and chemical engineering and mining extension at present a part of the College of Engineering in the West Virginia University would be transferred to the West Virginia School of Mines. It also is prescribed that the West Virginia School of Mines shall be organized as a part of the West Virginia University.

Capitalized at $75,000, the **Preston Smokeless Coal Co.** of Fairmont has been organized for the purpose of operating in the Preston County field. Active in organizing this company were J. S. Mallory, Gertrude W. Mallory, of Shinnston; H. S. Keister, Toyle A. Keister and M. B. Simmons, all of Fairmont.

The White Rose Coal Co. is the name of a new company with headquarters at Shinnston, organized for the purpose of operating in the Harrison County field. It has a capital of $75,000. Incorporators of the new concern were Urvin Smith, H. J. Wagner, George Beck and William Beck, all of Smithton, Pa.; John Parachino, of Greensburg, Pa.

George S. Connell of Charleston, has been appointed by President J. A. Clark, Jr., of the Northern West Virginia Coal Operators' Association as a member of the scale committee for the ensuing year. This committee negotiates wage scales for the Fairmont region with the United Mine Workers.

WYOMING

Frank Turner, of Rexburg, Idaho, is authority for the report that the **Blazon Coal Co.** is negotiating for the Star mine at Glencoe, near Kemmerer. L. F. Rains, president of the Blazon Coal Co., also operates the Carbon Fuel Co. and is identified with the newly organized Columbia Steel Corporation, both of Utah.

WASHINGTON, D. C.

Postmaster Merritt O. Chance has resigned as head of the Washington city post office to become first vice-president and secretary of the newly incorporated **Griffith Coal Corporation** of Washington. W. W. Griffith, incorporator of the new concern, is one of the oldest and largest coal dealers of the city.

Plans are being perfected whereby **coal-mining companies may obtain a lower rate on their group insurance** based on the percentage of their men who have been trained in first-aid and safety work by the Bureau of Mines. A further reduction is being arranged at those points where there is an active chapter of the Joseph A. Holmes Safety Association.

The U. S. Supreme Court on March 19 affirmed the decision of the Court of Claims **sustaining a demurrer entered by the government to the petition of the J. M. MacDonald Coal Mining Co.** for the difference between the price it received for coal under the Lever act and the price it claimed would have yielded it cost of production plus a just and reasonable profit. The government had demurred to the claim on the ground that the MacDonald company had no just claim as it had not complied fully with the regulations under the Lever act. The decision follows precedents in other cases arising out of this act.

CANADA

At a conference at Calgary, Alberta, on March 14, the Western Canada Coal Operators' Association and the miners of District 18, United Mine Workers of America, **renewed for another year their wage-rate agreement,** which terminates on March 31.

The charge before Judge Taylor, in the Criminal Court, at Edmonton, Alta., against W. M. Ryan, of the United Mine Workers of America, and 137 men for unlawful assembly having been dismissed, **the strike in the northern Alberta coal field has petered out,** though a little desultory picketing is still maintained. All the mines are being operated and the output is as great as it was before the strike was attempted.

The Illinois-Alberta well, in the Okotoks field, 35 miles south of Calgary, where a heavy flow of wet gas was struck recently, **caught fire on March 14,** and the derrick and equipment were completely destroyed, causing a loss estimated at $25,000. The fire was extinguished on March 16. The well was capable of producing about 40 barrels of gasoline and 3,000,000 cu.ft. of gas daily.

Sympathy toward the unionization idea but **distinct disapproval of any connection with the United Mine Workers of America** appears to be the attitude of miners in the Clover Bar and Edmonton fields. A new union has been formed, affiliated with the Canadian Federation of Labor, but not with the United Mine Workers.

The Dominion Government is to be asked to probe the whole question of coal mine operating costs and sales prices by the Associated Boards of Trade of Eastern British Columbia, which recently adopted this resolution "that this convention is of the opinion that price adjustments in the coal industry are long overdue and that in the interests of that industry itself, dependent industries, and the general public, such adjustments should be made forthwith, and that the Dominion Government should probe the whole situation."

The coal operators of the Province of Alberta are protesting against a proposed increase of compensation rate under the Alberta workmen's compensation act of from 55 to 66⅔ per cent, but there is no indication that Premier Greenfield's government is prepared to make any concessions. Representatives of the collieries admit that the change would appear to bring Alberta's rate on the same plane as that of other provinces, but they assert that comparisons are not fair because of the high wages paid in that province. In Ontario 66⅔ per cent is the basis, but there metalliferous miners receive $4.50 a day while in Alberta mines the wages are $7.50 a day and upward.

Association Activities

Pittsburgh Section of A.I.M.E.

On March 15 a dinner was held by the Pittsburgh section of the American Institute of Mining and Metallurgical Engineers, at which Chairman Crabtree introduced Edward Payson Mathewson, the new president. In his talk to the gathering Mr. Mathewson spoke of the aims of the institute and what each member should bear in mind to aid in its expansion, emphasizing the necessity of interesting young engineers in the work of the organization. He condemned state legislation which, if enacted, would require every engineer to be licensed. Instead of elevating the position of the engineer in public view, he said, such legislation would lower it by causing the masses to believe that every licensed engineer is a capable engineer, else he would not be licensed; that experience and name rather than a certificate of qualification should give rank to the engineer. Graham Bright was elected chairman of the Pittsburgh section for the coming year and the members voted that Mr. Goodale continue in the office of secretary.

International Railway Fuel Association

Periodical meetings in the principal railroad centers to stimulate interest in fuel matters is one of the activities recently undertaken by the International Railway Fuel Association. In December, 1922, President J. N. Clark, acting upon authority of the executive committee, requested members in some of the larger railroad centers to organize district chapters. This work is now being carried forward and the District of Columbia Chapter, which was organized on Jan. 10, 1923, has already held two meetings. The subjects discussed by this chapter included "Forms of Fuel Contracts," "Practicability of Fuel Purchased on Specification Basis," "Methods of Fuel Distribution by Direct Consignment from Mines to Coaling Station and Otherwise," and "Supervision of Locomotive Operation." The Chicago District Chapter held a meeting on March 12, at which W. E. Dunham, assistant superintendent of motive power and machinery of the Chicago & North Western R.R., presented a paper on "Cold Weather Practices as Related to Fuel Conservation." Each section will be allowed to work out its own program for the discussion of problems of local or general interest. It is thought that by holding informal meetings each thirty or sixty days the members will be able to carry out the objects of the organization to better advantage and to promote the best methods for fuel economy in their own territory.

Indiana Bituminous Coal Operators' Association

The Indiana Bituminous Coal Operators' Association, in annual meeting March 14, at the office of Phil H. Penna, secretary, elected the following officers for the year: E. D. Logsdon, president; Paul Zimmerman, vice-president, and P. H. Penna, secretary and treasurer. Executive board members elected were: H. M. Ferguson, Clinton, Ind.; M. L. Gould, Indianapolis; C. Zellar, Brazil; David Engle and James Moore, Evansville; John Connery and G. James Pauley, Chicago, Ill.; J. A. Templeton, Paul Zimmerman, A. M. Ogle, George C. Richards, J. C. Kolsem, Homer Talley, W. D. Freeman, Hugh Shirkie and Robert B. Smith, of Terre Haute.

Traffic News

The Baltimore & Ohio R.R. has just closed contracts for 75 additional locomotives, which it is expected will be delivered next autumn. They will cost approximately $75,000 each. Order for 25 of them was placed with the Lima Locomotive Works at Lima, Ohio, and 50 with the Baldwin Locomotive Works at Eddystone, Del. The plants of both of these companies are located on the lines of the B. & O.

A brief filed with the Interstate Commerce Commission by the Southwestern Interstate Coal Operators' Association and the Oklahoma Coal Operators' Association urges **the commission to prescribe reasonable and just rates on coal** from mines in Missouri, Kansas, Arkansas and Oklahoma to various destinations in Kansas, Missouri, Nebraska and Iowa, particularly to the cities and towns located on or in the vicinity of the Missouri River. The brief states that the Southwestern association is composed of 170 members and the Oklahoma association of 47 members.

The city of Zion City, Ill., has lost its appeal to the I. C. C. suit for cheaper coal rates from the mines. Rates on coal to Zion City have been found to be reasonable in the case filed by Zion City industries against the Evansville, Suburban & Newburgh R.R., Evansville, Ind.

The Coal, Coke & Iron Ore Committee, Central Freight Association territory, will hold a hearing April 12 in the Chamber of Commerce Building, Pittsburgh, Pa., **to consider the proposed establishment of a rate of $1.01 per gross ton on bituminous coal,** carloads, to 26th Street, 33rd Street, Pittsburgh (Duquesne) and Grant Street deliveries, Pittsburgh, Pa., from junctions with the Union R.R. (Pittsburgh, Pa.).

The **Coal, Coke and Iron Ore Committee, Central Freight Association territory,** will hold a hearing, April 12 in the Chamber of Commerce Building, Pittsburgh, Pa., **to consider the proposed establishment of a rate of $1.13 per net ton on bituminous coal,** carloads, to stations on the Baltimore & Ohio R.R. between Pine Grove, W. Va., and Bane, W. Va., inclusive, from origin points between Clauson, W. Va., and Hepzibah, W. Va., and from Limestone, W. Va., including mines and other points intermediate.

The matter of rates on slack from Arkansas and Oklahoma mines to Texas points will be the subject of oral argument before Division 2 of the Interstate Commerce Commission in Washington on April 26.

An embargo was placed March 14 by the Lehigh Valley R.R. against all shipments of bituminous coal for J. Skolik & Sons, Newark, N. J.

The Delaware, Lackawanna & Western R.R. has cancelled an embargo against all freight destined to all points via Delaware & Hudson Company, Binghamton, N. Y.

Embargo placed by the Delaware & Hudson Co., against traffic from Pennsylvania R.R., Lehigh Valley R.R., Central Railroad of New Jersey at Wilkes-Barre and Hudson, Pa., and from Delaware, Lackawanna & Western and Erie railroads at Binghamton, N. Y., and Lehigh Valley R.R. at Owego, N. Y., destined to points on or via the D. & H. Co., **is modified** by cancelling. Paragraph B of Sect. 2 which will now permit acceptance of all carload and less carload freight from D., L. & W. or Erie R.R. at Binghamton, N. Y., and from Lehigh Valley R.R., at Owego, N. Y., when destined to any D. & H. Co. station.

Embargo placed by the Boston & Albany R.R. against all carload freight from connecting lines at Albany, West Albany Transfer and Rensselear, N. Y., destined to points on or via the New York, New Haven & Hartford R.R. when routing via Springfield, Mass., **is entirely cancelled.**

On account of accumulation the Long Island R.R. on March 20 **embargoed all carload freight** for team track delivery at Elmhurst, N. Y., also all freight consigned to or intended for the Elmhurst Coal Co., Elmhurst, N. Y.; exceptions: livestock, perishable foodstuffs, for human consumption, field and garden seed, fertilizer and U. S Government freight.

On account of accumulation the Long Island R.R. on March 20 **embargoed all carload freight** requiring crane delivery at Flatbush Avenue Station, Brooklyn, N. Y.

On account of accumulation **an embargo** was placed March 20 by the Pennsylvania R.R. system **on all shipments of bituminous coal** consigned, reconsigned or intended for **delivery to the American Lime & Stone Co.,** Bellefonte, Pa. Shipments originate principally in the Pittsburgh and Clearfield districts.

Obituary

Charles Stewart Ramsay, for many years superintendent of the Dora division of the Pratt Consolidated Coal Co., Birmingham, Ala., but recently removed to Sanford, N. C., where he assumed the management of the Erskine Ramsay Coal Co., died in Birmingham, March 17, after an operation for appendicitis. Mr. Ramsay was 43 years of age and went to the Birmingham district about twenty years ago from Shafton, Pa., having been connected with the Pratt company since then, and was widely known and considered an able mining man. He was a brother of Erskine Ramsay, vice-president and chief engineer of the Pratt company, an engineer and inventor of national repute. He is also survived by his widow, five children and five brothers and three sisters. The body was sent to Shafton, Pa., for interment.

Calvin Pardee, who with his father, Ario Pardee, and brother, Ario, Jr., had a prominent part in the development of the anthracite industry of Pennsylvania, died March 18 at his home in Philadelphia. He was 81 years old and until a few months ago had been in active charge of his varied business interests. Mr. Pardee was a former president of the Lehigh Coal & Navigation Co., a director of the Lehigh Valley Railroad Co., the North Penn Railroad Co., the Tennessee & West North Carolina Railway Co., and of the Cranberry Iron, Coal & Furnace Co., of Tennessee.

John J. Brown, 71 years old, president of the Pittston Coal Co., for the last fifteen years, died March 20 at his home in Scranton, Pa. He was ill of complication for one month. Born in Carbondale on June 24, 1852, Mr. Brown lived in that city until he was twenty-three years old, working in a blacksmith shop. He later moved to Scranton, where he entered the employ of the Adams Express Company. He eventually became connected with the Garney & Short Cigar Company as a salesman, finally being made a member of the firm. For the last fifteen years he was head of the Pittston Coal Co. His wife, three sisters and a brother survive him.

Coming Meetings

National Retail Coal Merchants' Association will hold its sixth annual convention June 25, 26 and 27 at Scranton, Pa., with headquarters at the Hotel Casey. The registration fee of $15 will include all meals except breakfast, transportation to and from the mines which will be visited, and the banquets. The only other expenses to be incurred will be hotel room and transportation to and from Scranton. Executive secretary, J. E. O'Toole, Philadelphia, Pa.

National Safety Council will hold its twelfth annual safety convention at the Buffalo Statler Hotel, Buffalo, N. Y., Oct. 1-5. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

International First-Aid and Mine-Rescue meet will be held Aug. 27-29, at Salt Lake City, Utah.

American Institute of Electrical Engineers will hold its annual convention June 25-29, at Swampscott, Mass. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

The Virginia Coal Operators' Association will hold its annual meeting on April 21 at Norton, Va. Secretary, G. D. Kilgore, Norton, Va.

International Railway Fuel Association will hold its spring convention at the Hotel Winton, Cleveland, Ohio, May 21-24. Secretary-treasurer, J. G. Crawford, Chicago, Ill.

The American Mining Congress will hold its twenty-sixth annual convention in conjunction with the **National Exposition of Mines and Mining Equipment,** Sept. 24-29, at the Milwaukee Auditorium, Milwaukee, Wis. Secretary, J. F. Callbreath, Washington, D. C.

Indiana Retail Coal Merchants' Association will hold its annual meeting April 25 and 26 at the Severin Hotel, Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

American Society for Testing Materials will hold its annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, N. J., beginning June 25 and continuing throughout the week. Secretary, E. Marburg, Philadelphia, Pa.

The Colorado & New Mexico Coal Operators' Association will hold its annual meeting June 20 at Denver, Col. Secretary, F. O. Sandstrom, Denver, Col.

The Electric Power Club's annual meeting will be held at the Homestead, Hot Springs, Va., June 11-14. Executive secretary, S. N. Clarkson, Cleveland, Ohio.

National Foreign Trade Council will hold its annual conference May 2-4 at New Orleans, La. Secretary, O. K. Davis, 1 Hanover Square, New York City.

The Gas and Fuel Section of the American Chemical Society is arranging a second sectional meeting at the New Haven meeting of the American Chemical Society during the first week in April.

The eleventh annual meeting of the Chamber of Commerce of the United States will be held in New York City May 7-10.

National Coal Association will hold its sixth annual convention June 19-22 at Atlantic City, N. J. Assistant secretary, C. C. Crowe, Washington, D. C.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 23 NEW YORK, APRIL 5, 1923 Number 14

Set Them Up Again

GENERAL GOETHALS last week closed his desk with a bang, grabbed his hat and left the office of Fuel Administrator for New York State in a huff. Like other famous men he found the coal problem not a stone wall against which he could butt his head with super engineering skill but a simple elemental test in economics where bluster and fame came to crestfallen defeat. According to the New York *Globe*, the General declared his office was a joke and that in view of the way the coal situation was handled from Washington he would like a chance at once to vote in opposition to the Harding administration.

Of course what peeved the General is that his mighty person was not sufficient to obtain for New York State, his protégé, more than was coming to it. He flays the Pennsylvania Fair-Price Commission for allowing certain independents a fair price for their coal, he admits he would have let Canada freeze and recommends a program of nationalization that would out-Brophy Blankenhorn.

He may cool off some day when his offended dignity is once more enthroned and acknowledge that Woodin had the thing well in hand when he took hold.

The coal industry may be a fine place for a dictator, as he suggests, but we doubt if his candidacy would now be seriously considered.

What Is the Price of Coal?

IT IS more generally true than not that what the consumer is willing to pay sets the price of bituminous coal. This, of course, is true of any commodity in which there is no corner or monopoly. The consumer's interest may be largely influenced by purely psychological factors, either for or against high prices, as when a buying panic boosts prices or a buyers' strike depresses them. But the simple fact remains that with a commodity so freely competitive as soft coal the indifference or anxiety of the buyer is the chief factor in setting the price. This is particularly and more noticeably true with respect to the open-market or "spot" prices.

Several of our readers, representing smaller operations in the field, have recently called our attention to the fact that the spot prices at the mines quoted weekly in *Coal Age* often are higher by as much as 50c. than they can obtain for their product on corresponding dates. The answer is that the two figures are not necessarily comparable. The current quotations published by *Coal Age*, and presumably this is true of those published by our contemporaries, are prices to consumers —that is to say, the "market" on coal in those centers where trading is done.

It is a repetition of well-known facts to recite that coal is sold through three well-established channels of trade: Directly by the sales departments of producers, directly by sales agents acting for and in behalf of producers on contract arrangement with fixed compensation, and by independent wholesalers or jobbers. If on a given day in a given city, as for instance Philadelphia, where buying and selling of coal centers, buyers are disposed to place orders for current delivery of a given coal, say Fairmont medium sulphur steam run-of-mine, at prices ranging from, say, $2.50 to $3.25 per net ton at the mines, this fact will be evidenced by conversations between buyer and seller.

If the seller is the sales representative of a producer, either directly or through a sales agency, he can and does act on his own initiative, accepting orders at the price he can induce the buyer to accept. Against that price are the charges for selling before the mine is credited. In the case of the selling department of a producer this usually is cost, and for a sales agency a fixed percentage of sale price f.o.b. mines.

A variable but considerable tonnage is handled through independent wholesalers or jobbers. Smaller operators have middlemen to whom they are accustomed to turn when they have coal to sell, and each jobber has a list of producers to whom he may turn for coal when he has a buyer in prospect. Except during times of great urgency for supplies, when prices are high and panic conditions prevail, the producer and independent middleman on whom he depends for distributing his product have a rather loose but tangible connection. In many such instances there is a common understanding that the coal will be sold to best advantage and that settlement will follow at stated intervals.

In other instances, and this is more typical of the market today, the middleman makes the producer a flat offer on specified tonnage to match the firm offers of consumers. Or this middleman picks up coal "on wheels" at favorable prices, as the shipper on consignment feels the pinch of carrying the coal, and offers this "bargain" to the buying trade. In any event, to go back to our illustration of a market on Fairmont steam coal in Philadelphia, assumed to be on a certain day $2.50@$3.25, we find that the middleman, knowing that this top figure is his maximum and the lower figure the more likely for a quick turn, canvasses the field either through his local agent or by long-distance telephone, and offers $2 to the producer who either has mined the coal but has not sold it or who wants orders that he may run the next day. The producer who accepts business at $2, seeing a published quotation on coal from his field 25c. to 75c. above what he can get is disposed to say the published quotation is grievously in error.

It is difficult enough to round up data sufficient to report the market on soft coal within narrow limits as to grades and quality on the markets where buying and selling are most active, without attempting to cover the multitude of prices that obtain in the field among the smaller shippers, whose product has a wide range from

best to worst and whose values in the market have a correspondingly wide range.

What the producer gets for his coal is not by any means always the market, for to the best salesman go the best prices and a shipper without his own sales force must take what he can get. The price of coal is what the consumer pays.

These Three

THE three qualifications for a mine manager are character, intelligence and education. The first two are almost entirely innate. Education does little to give a man power of leadership, strength of will, quickness of judgment, patience, freedom from excessive sensitiveness, ability to express himself well, power of reserve—all the qualities that mark a man of the world. Education may even weaken character by making a man defer to the judgment of others and by inducing a man to lay more stress on the manner than on the matter of expression. It may make a man of narrow vision more meticulous than ever.

Intelligence also is largely innate. It is the ability to apply and reason about facts. It has little to do with the acquisition of a knowledge of them. Education probably develops intelligence but little. The reasoning faculty, what is called the intelligence quota—the I. Q. of the psychologists—soon reaches in life a given level after which it quite generally fails to increase. Many of the problems presented by life are answered rightly or wrongly partly from experience, education or group consciousness and not by reasoning at all. We appear to be more intelligent but are really only better educated.

If character and intelligence are really, or even only in the main, innate, then indeed it should occasion no surprise if education fail to make a man. The "educated fool" should not be any more a real matter of surprise and regarded as phenomenal than the short-sighted long-distance runner. We know that the powers of sight are distinct from the powers of locomotion. We do not assume that they are connoted, much less correlated. Why then expect education, intelligence and character always to be found in one man?

An educator was asked recently how he could expect to get results out of the untested material furnished him. He replied that it *was* tested—in examinations. That is to say, he tried to find if facts had stuck as a test as to whether other facts might be expected to stick. A splendid test if he was trying to find out whether he could educate his man, but useless if his purpose was to find out if the man was qualified to be a good business man with the three qualifications—character, intelligence and education. That educator was trying to tell the public that his graduates would have all three qualifications yet he could not give them the first two and could only add to the third.

Let the colleges end their clatter about how much they do for the character and intelligence of their students. They do about as much, and can do about as much, for these qualities as they do for the stature of their *protégés*. We presume that if the demand for tall men and fat men were vocal the schools would promise to make their graduates both tall and fat. Almost all that the colleges do is to inform. It is about all that they can be expected to do, and what a noble task it is!

Set an intelligent savage of character to figure out the operation of a motor—how far would his intelligence and his character take him? Could he learn the relative availability of a delta and a star connection? Could he lower a power factor? This is no reflection on intelligence or character except that it argues that they are not enough in themselves. We must have education. There is place in the world for men, even though they be low in both intelligence and character, as long as they are well educated. There is a reward for such men and a big reward for those who are well endowed with two of these and a bigger reward yet for those who have all three. Education does not accomplish everything but what it does is mighty well worth the doing.

"From the Pan Into the Fire"

ONE reads with a puzzled brow the "arguments" for nationalization of the coal industry, for the arguments are not arguments but protests. In the current issue of the *Outlook* C. J. Golden restates his view of nationalization, and John Spargo, "an authority on socialism," takes the contrary side. So far Mr. Golden and the school of thought which he follows have had one stock argument for taking over the coal mines and that is somewhat loosely defined as "fact finding." None of the advocates of taking over the mines offers argument or reason for such action. They agree in saying that they are not satisfied with present conditions; they want things changed and nationalization is the thing proposed. We believe they want the government to take over the mines because they consider this the simplest way to get everything they want—higher wages, less work, more power—everything everybody with human instinct and active appetite wants. For instance, Golden says "the first year [of nationalization] the miners' wages might be reduced, seeing the kind of representatives you've got here now in the government. But not the second year. The workers would soon learn not to vote for men who reduced them. When the representatives' political fates depended on it, we'd get fair conditions from them."

It is rather difficult to answer arguments as nebulous as those of Golden et al., but John Spargo summarizes the results of nationalization of industry as variously practiced and attempted and concludes that the plan "offers no present relief from the evils of the existing methods of producing and distributing coal, bad as they are. It simply invites us to jump from the pan into the fire."

The plea for nationalization as set forth by the miners is not likely in the last analysis to be seriously opposed by those who own coal properties and would sell them to the government. If the United Mine Workers want to buy the coal mines, they are for sale today and if they can get the taxpayers' money with which to make payments, well and good. Before that happens some who are not to be charged as speaking for the operators will challenge the proposal as opposed to public interest, for, as Spargo says, "it opens the way for an appalling amount of wastefulness and extravagance." Concluding, he says: "For the present at least I am free to say that I can see no hope of anything good or useful to be attained by any such extension of the power of the government and its preponderance over the economic life of the nation as has been suggested. On the contrary, the sooner we can lessen those powers, reduce the size of our governmental machine and its interference with the economic life of the nation, the better will it be for all of us."

Nanticoke Coal Is Thickest Though Deepest of All Measures in Northern Anthracite Field

Becomes 39 Per Cent Thinner and 271 Ft. Deeper in 50 Years—Inefficiency Cuts Mines' Output 24.3 Per Cent Since 1902—Four Plants Prove Value of Up-to-Dateness

By Dever C. Ashmead*
Kingston, Pa.

FIFTY years of hard-coal mining in the Nanticoke district of Pennsylvania's northern anthracite field—a district covering the western end of the field below Wilkes-Barre—has developed the widest variations in thickness and depth of coal measures to be found anywhere in the field. In spite of this and the presence of some troublesome displacements, the problems and general tendencies of the Nanticoke district parallel those of the Wilkes-Barre and Lackawanna districts, treated in preceding articles of this series. The average thickness has diminished from 11.5 ft. in 1872 to 6.83 ft. now—but it still is 1.95 ft. thicker than Lackawanna and 1.74 ft. thicker than Wilkes-Barre coal. This advantage is partly counterbalanced by the depth of the field—an average of 567 ft. compared with 399 ft. for Wilkes-Barre coal and only 268 ft. for Lackawanna. Of course pumping and haulage distance are increasing and are multiplying power costs.

Four big new collieries, producing in 1921 about 32 per cent of the district's output, have had a deep influence on Nanticoke statistics. They indisputably prove the value of modern methods and equipment. While the average output per day per man in the whole district in 1921 was 2.02 tons, it would have been only 1.86 tons if the data on the four had been omitted. The output per outside man would have been 8.20 tons instead of 9.43 tons. A decrease in the average Nanticoke miner's production from 5.34 tons in 1902 to 4.04 tons in 1921 can be explained only by charging the miners with inefficiency.

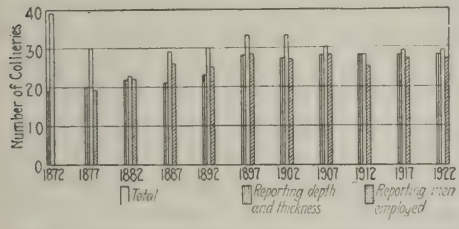

FIG. 25—NUMBER OF COLLIERIES CONSIDERED IN THE NANTICOKE DISTRICT

This shows in the first column of each period the number of collieries which reported on thickness and depth. The second column gives the number of collieries reported by the State Department of Mines and the third column gives the number used in the tonnage calculations.

Practically all of the Nanticoke district collieries furnished complete information for the years from 1882 to 1922 (Fig. 25 and Table XXI). Even for 1877 reports are available from about 50 per cent of the collieries. So the curves plotted on this data give a good picture of what has happened in this district. This series of studies has been confined as nearly as possible to fresh-mined coal. Washery tonnage has been omitted, except washed coal that could not be separated from the breaker output. Strippings did not have to be considered in this district, as there are none of any importance.

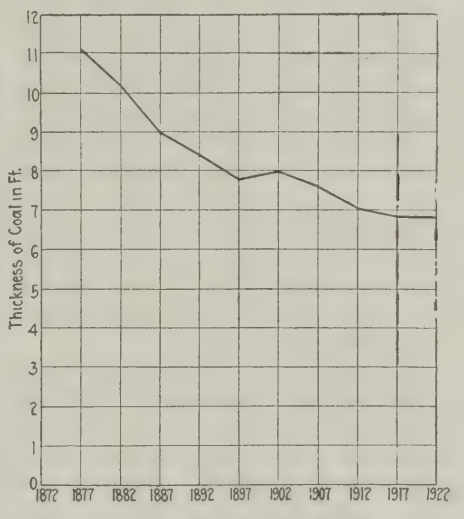

FIG. 27—AVERAGE THICKNESS OF NANTICOKE COAL BEDS BY FIVE-YEAR PERIODS FROM 1872 TO 1922

In the first section of this article under Fig. 3 (*Coal Age*, Vol. 23, p. 324) there was a complete description of the method used in the calculation of this curve. The main feature to be noted in this curve is the general decrease in the average thickness of the beds.

The geological conditions in the Nanticoke district are distinctive. Mines vary from shallow workings to some of the deepest in the northern anthracite region. One of the shafts sinks 1,800 ft. The majority tap deep-lying beds. About four miles west of Wilkes-Barre the coal is deepest. From that point west the measures rise and on the top of the mountain back of Shickshinny the beds spoon out. On both sides of the basin but especially on the south side steep pitches are encountered. Fig. 26 is an actual section of this district. It will be noted that there are a few heavy faults

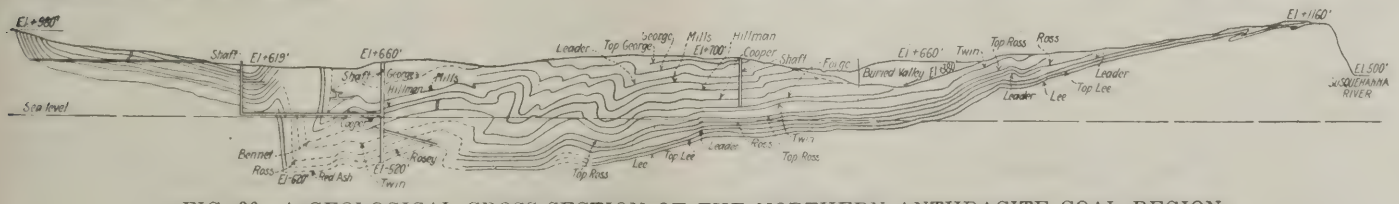

FIG. 26—A GEOLOGICAL CROSS-SECTION OF THE NORTHERN ANTHRACITE COAL REGION IN THE VICINITY OF NANTICOKE

Complete cross-section of the field made near the City of Nanticoke. Working beds are in the heavy black lines. Dotted lines represent beds located by estimate. The faults shown cause considerable displacement and steep pitches in the vicinity of the faulted area. As the beds approach the outcrop on the southern side of the field they become steeply pitching. The "buried valley" is indicated by the heavy wash shown in the center of the cross-section.

FOOTNOTE—This is the third of a series of articles by Mr. Ashmead describing mining conditions in seven sections of the anthracite region. The first and second articles appeared in *Coal Age*, on Feb. 22, 1923, and March 22, 1923. The fourth will appear in an early issue.

*Assistant editor of *Coal Age*.

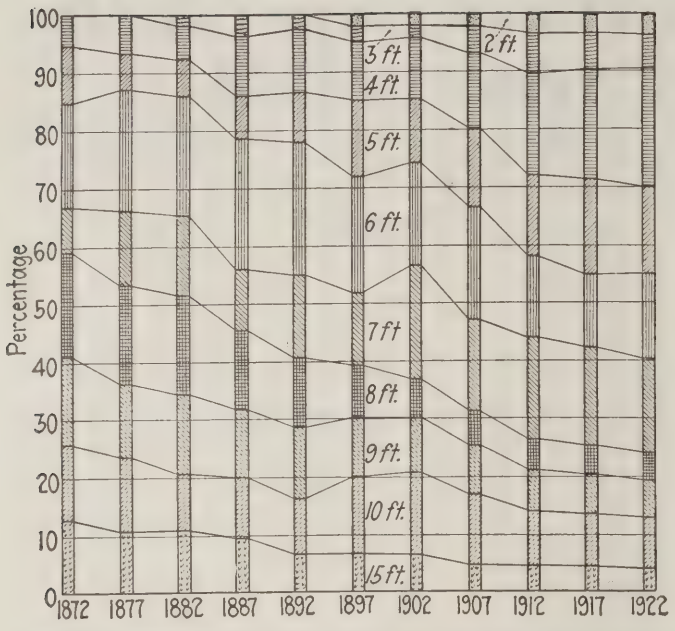

FIG. 28—PERCENTAGE OF EACH THICKNESS TO TOTAL NUMBER OF NANTICOKE BEDS

The variation in the thickness of the beds by 5-year periods from 1872 to 1922 is shown by this curve. The method of arriving at these percentages has been described in the first part of this article under Fig. 4 (*Coal Age*, Vol. 23, p. 324).

that cross the beds, causing considerable displacement and some steep pitches.

The "buried valley"—a continuation of the one mentioned in the description of the Wilkes-Barre district (*Coal Age*, Vol. 23, p. 475)—extends through this district also, from Pittston to a point west of Nanticoke. The cross-section shows that the bottom of the "buried valley" near Nanticoke is about 200 ft. below the surface. Here also some of the beds of coal outcrop in this valley, making the workings near the valley dangerous.

In this district probably more coal is being recovered from first mining in proportion to the total output than in either the Wilkes-Barre or the Lackawanna district.

A list of the beds from the surface downward as they occur in the Nanticoke district follows: Top George, George, Orchard, Mills, Hillman, Cooper, Bennett or Forge, Twin, Top Ross, Ross, Rossy, Top Lee and Lee (Red Ash).

In this district are found the thickest beds in the northern anthracite region, averaging 6.83 ft. In 1877 they showed a weighted average thickness of 11.19 ft.

TABLE XXI—NUMBER OF NANTICOKE DISTRICT COLLIERIES IN THIS STUDY

	Reported by Inspectors	Having Depth Data	Having Thickness Data	Having Tonnage Data
1872	39	19	19	0
1877	30	15	15	14
1882	23	22	22	22
1887	29	21	21	26
1892	30	23	23	25
1897	33	28	28	28
1902	33	22	22	22
1907	30	28	28	28
1912	28	28	28	25
1917	29	28	28	27
1922	29	28	28	27

TABLE XXII—WEIGHTED AVERAGES OF NANTICOKE BEDS

Years	Thickness of Beds	Depth of Workings	Years	Thickness of Beds	Depth of Workings
1877	11.19	296	1902	8.02	524
1882	10.24	335	1907	7.67	540
1887	9.02	346	1912	7.09	526
1892	8.43	414	1917	6.86	567
1897	7.81	484	1922	6.83	567

TABLE XXIII—PRODUCTION PER BOILER-HORSEPOWER AND PER ENGINE HORSEPOWER

Year	Boiler H.P. Installed	Engine H.P. Installed	Tons of Coal Produced Per Boiler H.P.	Tons of Coal Produced Per Engine H.P.
1877	8,370	.....	1.75	...
1882	14,400	20,425	1.22	.86
1887	21,000	.....	1.16	...
1892	25,220	.....	1.18	...
1897	35,780	.....	1.08	...
1902	52,449	70,272	.81	.61
1907	59,599	81,398	.84	.61
1912	64,398	83,962	.79	.60
1917	60,819	83,161	.72	.53
1921	60,391	.....	.77	...

Most of the coal then mined in the district was in the Cooper, Bennett and the Red Ash beds. These are the thick beds of the district. Judging by figures available for 1872, the weighted average thickness in that year was about 11.5 ft. But as 1872 production figures are not available for individual collieries the average thickness can only be estimated and therefore is not shown in the curve. Fig. 27 and Table XXII show the steady decline to 6.83 ft. in 1922. In the first 20 years of the period the decrease was 3.38 ft. while in the last 25 years it was but 0.94 ft.

TABLE XXIV—MULE AND LOCOMOTIVE HAULAGE IN NANTICOKE DISTRICT

	Tons of Coal Hauled Per Mule Per Day	Number of Underground Locomotives Per 100,000 Tons of Coal Produced Per Year		Tons of Coal Hauled Per Mule Per Day	Number of Underground Locomotives Per 100,000 Tons of Coal Produced Per Year
1877	19.54	....	1902	18.85	.10
1882	16.27	....	1907	19.58	.50
1887	15.81	....	1912	23.35	1.00
1892	15.92	....	1917	28.65	1.60
1897	21.35	....	1921	28.70	2.36

Fig. 28 shows that there were fewer thin beds being mined in this district than in either the Lackawanna or the Wilkes-Barre districts, for in 1922 the beds under 3 ft. in thickness were only about 3.5 per cent of the total and those under 4 ft. only 9.25 per cent. Mining in beds less than 4 ft. thick did not start until 1882 and no 3-ft. beds were opened until 1897. The whole diagram, however, shows that thick-vein operation is steadily decreasing and thin-vein work is increasing.

In coal measures so deep as these it is not surprising that the weighted average depth of workings is greater than in either of the two districts previously described. The rate of increase in depth also is greater. Fig. 29 and Table XXII show that 296 ft. was the weighted depth of workings in 1877 — the first year in which complete data were available. In 1872 the unweighted aver-

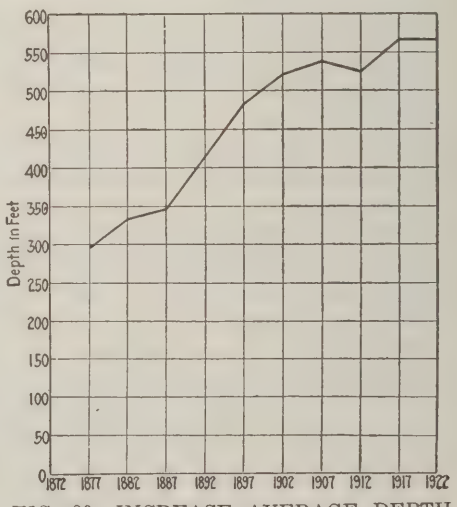

FIG. 29—INCREASE AVERAGE DEPTH OF NANTICOKE WORKINGS

Weighted average by 5-year periods is shown by this curve. The method of calculation is similar to that used in calculating the average depth under Figs. 3 and 5 in the first part of this article (*Coal Age*, Vol. 23, pp. 324-325).

TABLE XXV—NUMBER OF MULES AND LOCOMOTIVES IN NANTICOKE DISTRICT

	Number of Mules	Number of Underground Locomotives		Number of Mules	Number of Underground Locomotives
1877	750	....	1902	2,257	13
1882	1,078	....	1907	2,550	75
1887	1,544	....	1912	2,168	151
1892	1,861	....	1917	1,530	211
1897	1,960	....	1921	1,630	330

age depth of workings was 230 ft. This figure was not used in plotting the curve.

The increase in depth during the period 1877 to 1887 was only 50 ft., or at the rate of 5 ft. per year, but from 1887 to 1907 the increase in depth was 194 ft., or 9.7 ft. per year. From 1907 to 1922 the curve levels out, showing a difference of only 27 ft. in 15 years, or 1.8 ft. per year. The total difference between 1877 and 1922 was 271 ft., or an increase in average depth of 92.2 per cent. If the unweighted average of 1872 is used, then this difference in depth would increase to 337 ft., or to 146.5 per cent.

Fig. 30 illustrates very clearly how the depth of workings increased, especially from 1887 to 1902. In 1872 no beds were mined deeper than 500 ft. and 45 per cent of them lay between the 200- and 300-ft. intervals. In the following 5-year period the maximum depth increased to 600 ft. and then almost every period showed an increased maximum depth until 1902, when the maximum remained stationary at between 1,300 and 1,400 ft. Since then there has been no increase in depth except in 1912, when for a short period beds of coal were mined in the 1,600-1,700-ft. interval.

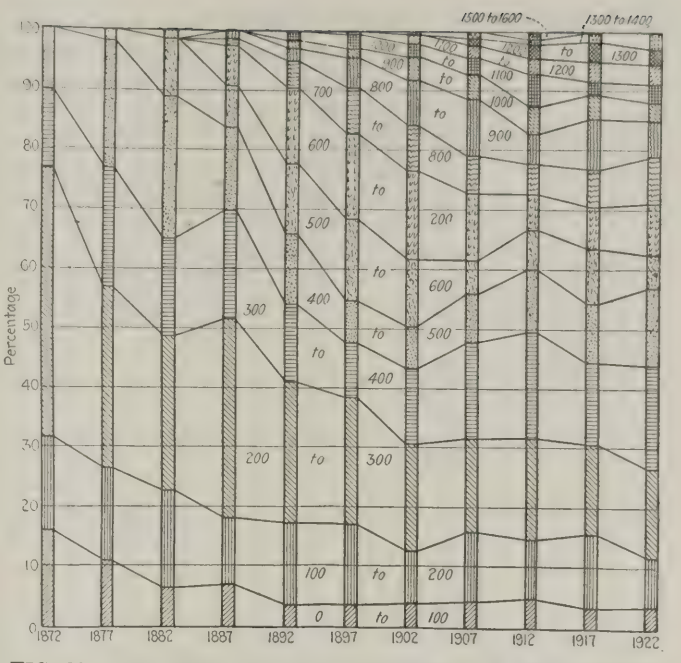

FIG. 30—PER CENT OF TOTAL NUMBER OF BEDS BEING WORKED IN EACH 100-FT. INTERVAL

A full description of the method used in calculating these percentages for the Nanticoke district, beginning with 1872 and by 5-year periods, will be found in the first installment of this article under Fig. 6 (*Coal Age*, Vol. 23, p. 325). The noteworthy feature is the almost steady increase in the depth of workings.

TABLE XXVI—TONS PRODUCED AND WEIGHTED AVERAGE DAYS WORKED IN NANTICOKE DISTRICT

	Tons of Coal Produced	Weighted Average Number of Days Worked		Tons of Coal Produced	Weighted Average Number of Days Worked
1877	2,042,630	150	1902	4,448,708	114
1882	3,702,621	234	1907	9,624,149	225
1887	6,181,958	240	1912	9,963,868	220
1892	5,502,946	203	1917	11,750,030	285
1897	5,665,252	147	1921	13,017,992	279

The curves in Fig. 31 tell the same story—as the depth increases the thickness decreases. Practically every interval shows that the average thickness of the beds has decreased and that the increase in depth has been steady until the most recent periods.

Nanticoke district development is steadily progressing—the depth of workings has almost doubled and thickness of beds has dropped more than one-third in the past 45 years. Power requirements naturally are greater, as is shown in Fig. 32 and Table XXIII. In 1877 for every boiler horsepower installed there was produced 1.75 tons of coal. In 1921 there was only 0.77 ton produced. Thus the decrease was 56 per cent. Expressing it inversely, in 1877 0.57 boiler horsepower was required for each ton of coal produced per day, compared with 1.30 boiler horsepower in 1921.

This increase in power required has not been due entirely to the thinning out of coal beds. Greater depth, increased volume of water to be pumped and longer haulage have made power demands even greater than have the preparation plants which clean this thin coal.

Production increases naturally have had their reflection on power consumed. Table XXVI shows how great has been the increase in the production since 1872.

TABLE XXVII—TONS OF COAL PRODUCED PER DAY IN NANTICOKE DISTRICT

	Total Men Employed			Inside Men Employed			Outside Men Employed		
	Actual	Corrected for Sizes	Corrected for Time	Actual	Corrected for Sizes	Corrected for Time	Actual	Corrected for Sizes	Corrected for Time
1877	2.03	2.98	2.56	3.15	4.62	4.20	5.71	8.37	6.59
1882	1.66	2.36	2.07	2.52	3.58	3.31	4.91	6.97	5.57
1887	1.73	2.21	1.86	2.57	3.29	3.05	5.26	6.72	5.38
1892	1.79	2.29	1.89	2.67	3.22	2.95	5.62	6.91	5.52
1897	2.12	2.48	2.19	3.05	3.57	3.30	6.96	8.24	6.59
1902	2.17	2.32	2.07	3.08	3.30	3.06	7.45	7.99	6.61
1907	2.08	2.21	2.07	2.79	2.96	2.83	8.20	8.71	7.75
1912	2.05	2.13	2.01	2.65	2.75	2.64	9.15	9.50	8.46
1917	2.01	2.01	2.01	2.63	2.63	2.63	8.46	8.46	8.46
1921	2.02	2.02	2.02	2.58	2.58	2.58	9.43	9.43	9.43

TABLE XXVIII—AVERAGE DAILY PRODUCTION OF INSIDE MEN

	Miners and Miners' Laborers		Inside Company Men		
	Actual	Corrected for Small Sizes	Actual	Corrected for Small Sizes	Corrected for Time
1877	6.02	8.83	6.63	9.73	7.77
1882	3.73	5.28	7.72	10.95	8.76
1887	3.73	4.76	8.30	10.60	8.48
1892	4.17	5.13	7.14	8.77	7.02
1897	4.50	5.26	9.52	11.12	8.89
1902	4.99	5.34	8.07	8.64	7.15
1907	4.39	4.66	7.66	8.14	7.25
1912	3.96	4.11	7.98	8.28	7.39
1917	4.26	4.26	6.90	6.90	6.90
1921	4.04	4.04	7.12	7.12	7.12

In that year 2,042,630 tons of coal was mined in the Nanticoke district. In 1921 13,017,992 tons was produced. Of course all of this increase did not come from the deepest workings but depth in many mines registered on the power curve of many mines.

The length of haul has increased notably. This increase will continue with development work in many of the largest collieries for an extended period. Fig. 33 and Table XXIV show the haulage curve for the Nanticoke district. In 1877 the average haul was short and the output per mule per day high. As the haul lengthened the output per mule decreased and by 1892 it had dropped to 15.92 tons per mule per day. Then the curve mounted as the use of underground locomotives increased. This increase is shown by the number of locomotives per 100,000 tons per year.

It is reasonable to suppose that if the underground

locomotive had not been introduced there would have continued to be a slight decrease in the amount of coal hauled per mule per day. If this is true then the curve indicated that the amount of coal hauled per mule in 1897 might have been 15.6 tons; in 1902, 15.5 tons; in 1907, 15.4 tons; in 1912, 15.3 tons; in 1917, 15.2 tons, and in 1921, 15.1 tons. Assuming this reasoning to be correct it is possible to calculate the amount of coal hauled per underground locomotive in the years 1902 to 1921 thus: 581 tons per day in 1902, 142.3 tons in 1907, 115.3 tons in 1912, 96.6 tons in 1917 and 67.2 tons in 1921. This shows that the output per locomotive is decreasing, and if it is decreasing then the power required to haul the coal is increasing.

This decrease in the production per locomotive is to be expected because when they were first introduced they were exclusively used on main-line haulage. Mules did the gathering. Now the construction of the locomotive has been so improved that with its cable-and-reel or with storage-battery power it can actually take the place of the mule and be used to gather coal. This reduced the number of tons per locomotive, however.

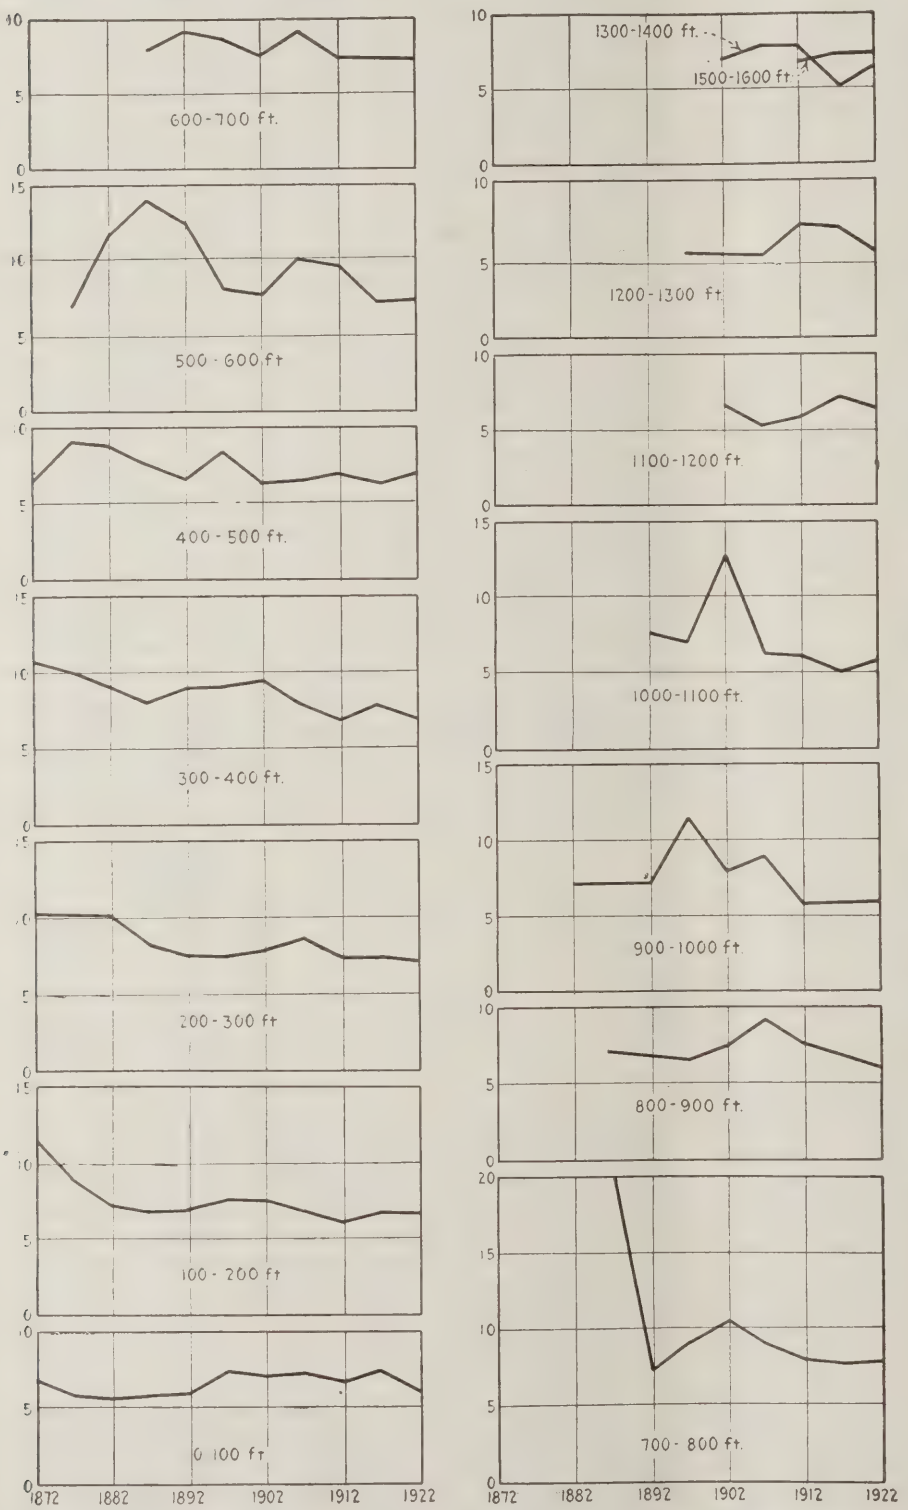

FIG. 31—SIMPLE AVERAGE THICKNESS OF BEDS AT EACH 100-FT. INTERVAL

In the footnote under Fig. 7 in Part I of this series of articles (*Coal Age*, Vol. 23, p. 326) will be found a full description of the method of calculating these curves and the points that these curves bring out will be found in this text.

No underground locomotives were reported in use in 1897, but by 1921 they had increased in this district to 330 and the number per 100,000 tons output increased from nothing in 1897 to 2.36. In spite of the absence of inspectors' reports on them in 1897 it is quite likely that a few were in use, as the locomotive was introduced into the anthracite region in 1887.

In this district are the two largest anthracite operations in the world. These two collieries had a total output of 3,123,353 tons in 1921, or 21.1 per cent of the outupt of the district. There are four collieries in this district which had a total output of 4,207,908 tons in 1921, or about 32.3 per cent of the whole output. These collieries might well be classed as new operations and ones at which there is a great deal of development work being done. These four new operations naturally have a deep effect on the district statistics.

The lowest set of curves in Fig. 34 and the data from which they were plotted in Table XXVII—the first three columns—show the production of coal per day per employee. The curve plotted from the actual figures obtained from the mine inspectors' reports is the solid line. This curve, generally speaking, shows a decrease in the earliest period and then a rising production per man until 1902, when the line is level or tends slightly downward. If these figures are corrected for the small sizes of coal which were not shipped in the earliest years, then the dash line, which represents this correction, shows a decrease in the total output per man per day, but when corrected for the time factor, as is shown in the dot-and-dash line, then there is a downward swing to the curve for the first ten years and upward for the next 10 years, and from this point it becomes practically a straight line for the last 24 years.

On this curve in particular the influence of the four big collieries is shown. Being new operations and having modern equipment they are able to produce their coal with more

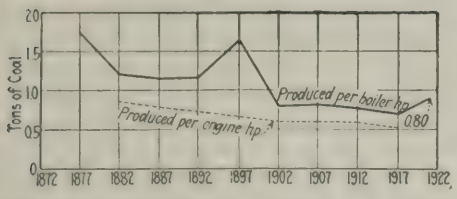

FIG. 32—NUMBER OF TONS OF COAL PRODUCED PER DAY PER BOILER HORSEPOWER

The calculation of the points on this curve and the sources from which the data were obtained will be found under Fig. 8 in the first of this series of articles (*Coal Age*, Vol. 23, p. 326).

efficiency than the older operations. If these collieries had been left out in calculating the curves, then in 1921 the output per man per day would have been 1.86 tons instead of 2.02 tons, as is shown by the curve. This indicates that great savings can be obtained at thoroughly modern equipped collieries. At another colliery in this district, old in years but new in the light of modern practice, the output per man per day is 2.22 tons, or considerably above the average for the district. This will be brought out more clearly in the detail curves that will be taken up later, and the reasons for this increased efficiency will be discussed.

The middle set of curves in Fig. 34 and the middle three columns in Table XXVII show the output per day per inside employee. The solid line shows the actual figures obtained from the mine inspectors' reports. Here again there is a decreasing output in the first period, a steady increase until 1902 and then a decrease until 1921. But when this set of curves is corrected for the per cent in sizes of coal which were not shipped in the early periods, the dash line results and the curve slants downward. The same condition results when the dash line is corrected for the time factor. The dot-and-dash line is produced showing the final corrected figure of output per inside man per day.

TABLE XXIX—MEN EMPLOYED IN NANTICOKE DISTRICT

	Total No. of Employees	No. of Inside Employees	No. of Outside Employees	No. of Miners and Miners' Laborers	No. of Inside Company Men
1877	6,707	4,324	2,383	2,346	1,978
1882	9,504	6,286	3,218	4,237	2,049
1887	14,909	10,013	4,896	6,911	3,102
1892	15,125	10,303	4,822	6,497	3,806
1897	18,108	12,583	5,525	8,547	4,036
1902	17,898	12,657	5,241	7,817	4,840
1907	20,572	15,350	5,222	9,759	5,591
1912	22,072	17,120	4,952	11,437	5,693
1917	20,492	15,627	4,865	9,658	5,969
1921	23,075	18,124	4,951	11,560	6,564

Let us see what would have happened to the curve if the before mentioned collieries were not considered in its calculations. In 1921 the curve shows an output of 2.58 tons per inside man, whereas if they had not been considered the output would have fallen to 2.40 tons per day. The old colliery with modern equipment shows an output of 2.81 tons per inside man per day, which is a considerable increase over the output of the district. At this operation there is some stripping, which increases the output of the inside men per day, and, as will be shown later, decreases the output per inside company man per day.

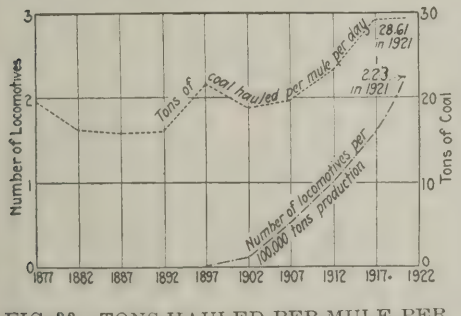

FIG. 33—TONS HAULED PER MULE PER DAY AND NUMBER OF UNDERGROUND LOCOMOTIVES PER 100,000 TONS

Table XXIV gives the points from which these curves for the Nanticoke district from 1877 were plotted and Table XXV shows the number of mules and locomotives in the district. The method used in making the calculations is described under Fig. 9 in the first part of this series (*Coal Age*, Vol. 23, p. 327).

The upper set of curves in Fig. 34 shows the number of tons of coal produced per day per outside employee. The figures from which this curve was plotted will be found in the last three columns of Table XXVII. Here, as usual, the whole tendency of the curve is upwards, with the exception of two periods, one in 1877 to 1882 and the other in 1917. The correction for the output of small sizes in the earlier years shows the same thing though less markedly. But the final corrections, which allow for both size and time, change the curve considerably. With the exception of the first two periods the curve is steadily upward.

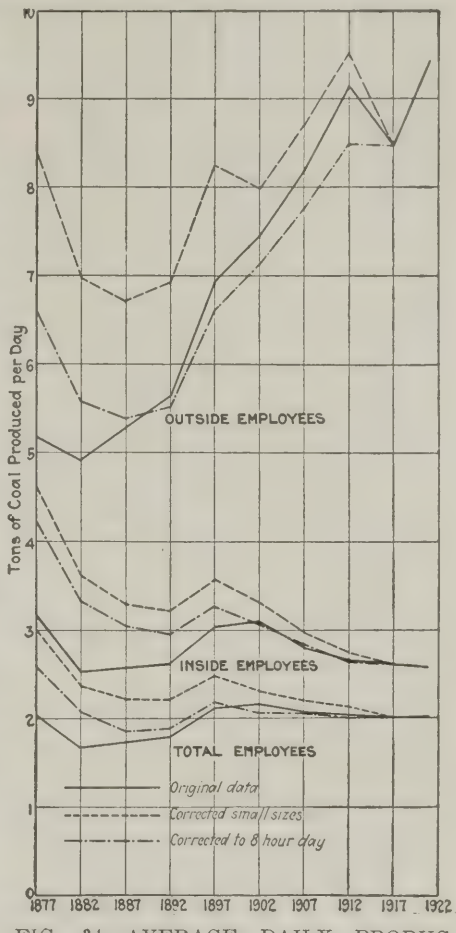

FIG. 34—AVERAGE DAILY PRODUCTION PER EMPLOYEE IN THE NANTICOKE DISTRICT, 1877 TO 1921

These figures were obtained from the mine inspectors' reports. The amounts represented by the solid line were corrected for the small sizes of coal not shipped in the earlier years and the dash line resulted. The dash line was corrected for the introduction of the 9-hour and 8-hour day for all employees except miners, resulting in the dot and dash line. The details as to the methods used and the amount of the corrections will be found under Fig. 10 in the first of this series of articles (*Coal Age*, Vol. 23, p. 327). The middle curves for inside men and upper curves for outside men are determined in the same way. Actual figures are in Table XXVII.

In 1887 the output per outside man dropped to 5.38 tons per day, the lowest in history. In 1921 it attained 9.43 tons. This was an increase of 75 per cent. The explanation of this lies mainly in the performance of the same "big four" collieries. These collieries are modern in every respect. They have labor-saving devices and new and modern breakers which greatly reduce the man power required and correspondingly increase the output per man employed.

If the four collieries had been omitted from the calculations in 1921, then the output would have been 8.20 tons per outside man per day instead of the 9.43 tons shown by the curve for 1921. The fifth colliery shows an output per outside man of 10.73 tons. The increased output per man in this case is due to the consolidation of the surface plants and the preparation of the coal from what were five old collieries in one modern breaker.

In the lower set of curves in Fig. 35 will be seen the result of the work of the anthracite miner in the Nan-

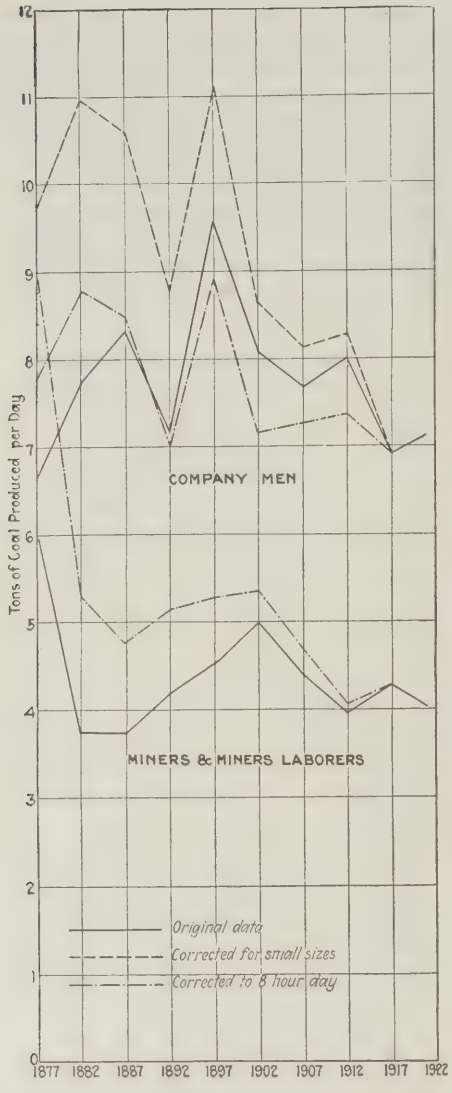

FIG. 35—DAILY PRODUCTION FOR INSIDE EMPLOYEES IN NANTICOKE DISTRICT, 1877 TO 1921

These curves are based on mine inspectors' reports and show corrections for the estimated amount of small sizes of coal that went into the culm banks in the earlier years and also for the introduction of the 9- and 8-hour day affecting inside company men. The method of making these calculations is explained under Fig. 11 in Part I of this series (*Coal Age*, Vol. 23, p. 328).

ticoke district in the past 44 years. The solid black line shows the actual figures as calculated from data published in the mine inspectors' reports, and the dot - and - dash line shows these actual figures corrected for the small sizes of coal not shipped in the earlier years. Here it was unnecessary to correct for the time element, as has been previously explained in the first of this series of articles. The first two periods show a sharp decline in the output per miner and miners' laborer. But from 1887 to 1902 the output per man rises.

Between this period and the one following, two of the four new and modern mines became large producers, in 1912 another one joined that class and in 1917 the last of the four reached its full output. With about one-third of the production coming from four up-to-date mines the production per miner and miners' laborer fell from 5.34 tons of coal per man employed in 1902 to 4.04 tons in 1921, or about 24.3 per cent!

This is difficult to explain. The bed thinned down only 14.8 per cent from 8.02 ft. to 6.83 ft. and a thinning bed is about the only physical factor that greatly effects daily output per miner. Since output increased 1.1 per cent from 1882 to 1902 while the average thickness of bed decreased from 10.24 ft. to 8.02 ft., or 21.5 per cent, and that in a period when little "modern" machinery was being introduced, it can only be concluded that miners then were more efficient than they are at the present time.

Even in the case of miners and miners' laborers had it not been for the four big collieries the output per man would have been as low as 3.80 tons in 1921, again demonstrating the fact that modern equipment and methods are bound to raise per-man output. Probably the haulage increases the output of men in the modern collieries, for the fifth colliery of the outstanding group —one that had been modernized—shows an output of 4.28 tons per man, or 0.24 tons more than the district average. A better haulage system permits the miners to receive a better turn and therefore permits them to load more coal per day up to a certain point. This point of limitation of output will be explained in a later article.

The upper set of curves in Fig. 35 and the figures in the last three columns in Table XXVIII show the change in the output of inside company employees per day, the heavy line being the actual figures as calculated from the mine inspectors' reports. This line was then first corrected for small sizes and the dash line resulted, then this line was corrected for the time factor, and the dot-and-dash line gives the final correction for the Nanticoke district.

If the doubtful 1897 figures are rejected as being in error and the average of 1892 and 1902 is taken in its place and then a curve is drawn for the average output per man per day, the curve will show a decided drop

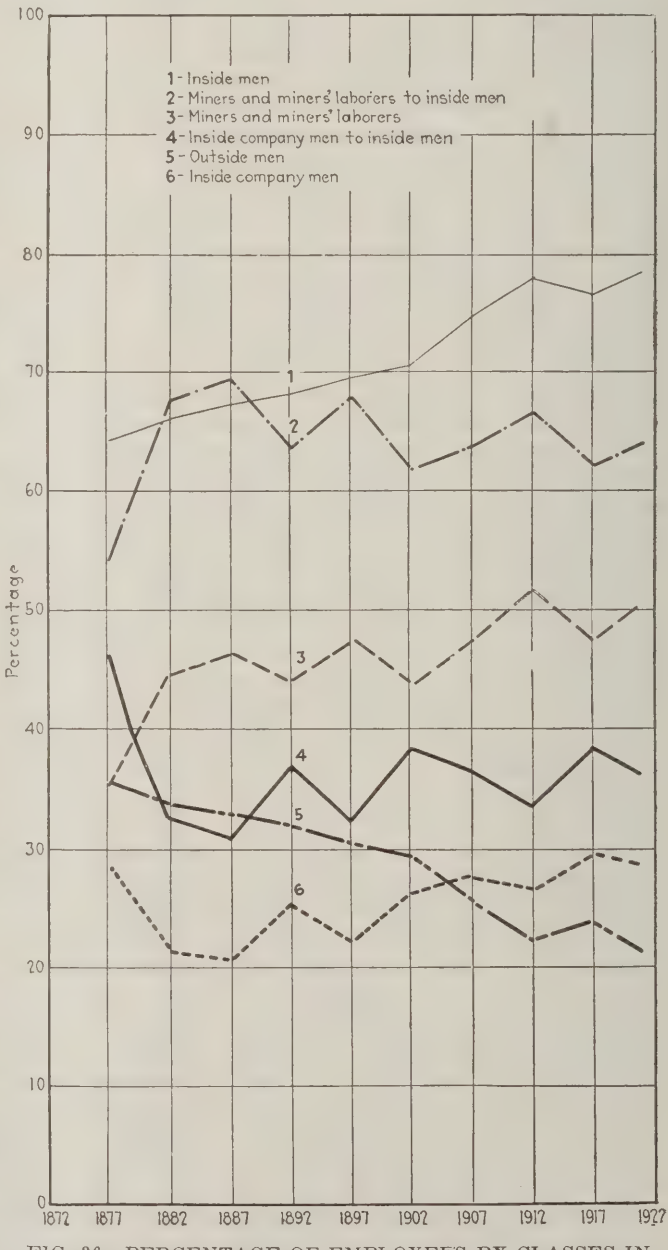

FIG. 36—PERCENTAGE OF EMPLOYEES BY CLASSES IN NANTICOKE DISTRICT

With the exceptions noted, the percentages shown are of each class to total men employed.

in the first three periods, but from then on it becomes practically level and there is no change in the output from 1892 to 1921. This is readily explained by the influence of the four modern collieries on the number of men employed. The equipment at these mines reduced the number and therefore increased the output of inside company employees. This was sufficient to counterbalance the loss in production per inside company employee at the older collieries, thereby keeping the curve level.

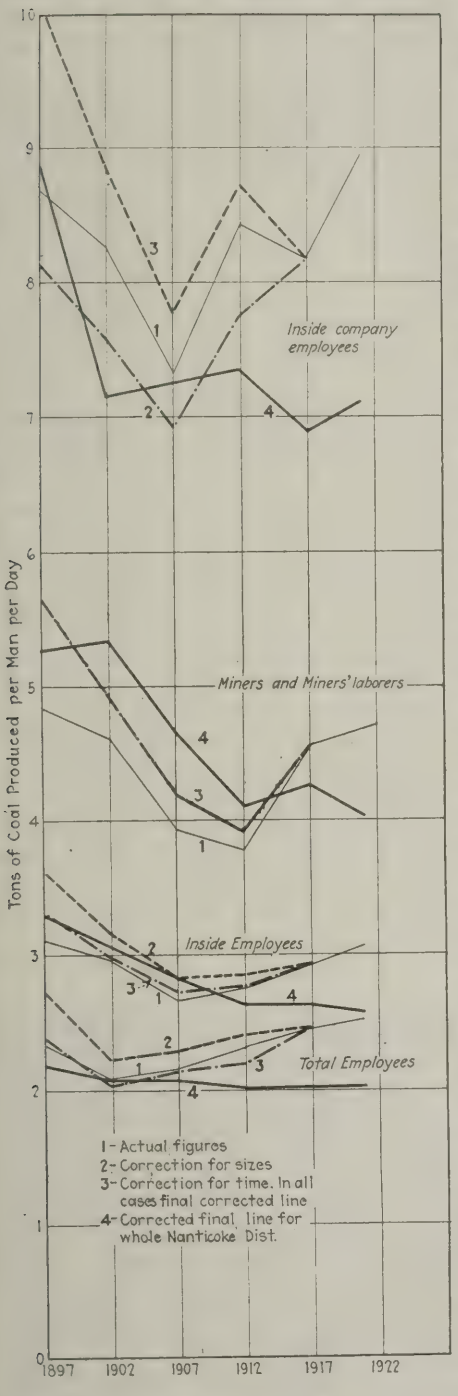

FIG. 37 — COMPARISON OF LABOR STATISTICS AT FOUR MODERN COLLIERIES WITH THE DISTRICT AVERAGES

The light solid lines are actual figures for the collieries, the dash line the correction for sizes and the dot and dash line the correction for time. In the case of the miners and miners' laborers it shows the correction for sizes only. In every case the dot and dash line is the final corrected line and the comparisons drawn in the text are between this line and the heavy black line, which is the final corrected line for all of the collieries in the district. This diagram covers all except the outside employees, for which see Fig. 38.

The average daily output per inside company employee for the four companies mentioned is 9.62, 7.96, 11.21 and 7.56 for the year 1921, which is very much above the 7.12 average for the district. When these figures are weighted to obtain a true average they affect the totals even more. If they were omitted from the calculations in 1921, then the weighted average for the remaining collieries would be 6.49 tons per man per day, which is 0.63 ton per man less than the average for the district. Even the fifth colliery, which has been continually mentioned in this discussion, shows an output per man of 6.58 tons, which is less than the average for the district but is greater than the average would have been without the "big four" collieries.

Fig. 36 shows the relationship between the different classes of employees and, as in the preceding diagrams of similar type in this article, the per cent of the inside men to the total men employed increases while the outside force decreases, which shows that the savings in men employed is in the outside force.

It is interesting to compare the new collieries in the Nanticoke district with old ones that have been modernized. Previous to 1897 these modern operations did not exist. Two were started then with comparatively small tonnages. It was not until 1907 that they became large producers. The third colliery became a large producer in 1912 and the fourth in 1917.

The curves in Fig. 37, on the production of coal per day per total men employed, show that the output per day has steadily increased from 1912 to 1921, while for the district there has been a steady decrease. True the decrease was small, but if these four collieries had not been included it would have been much greater. The increase in production at the modern collieries was 0.45 ton per man, or 21.5 per cent.

The curves for inside employees show that in the earlier years the average for the district was greater than for the new collieries. This is to be expected and is readily explained by the fact that large numbers of men were used for development work

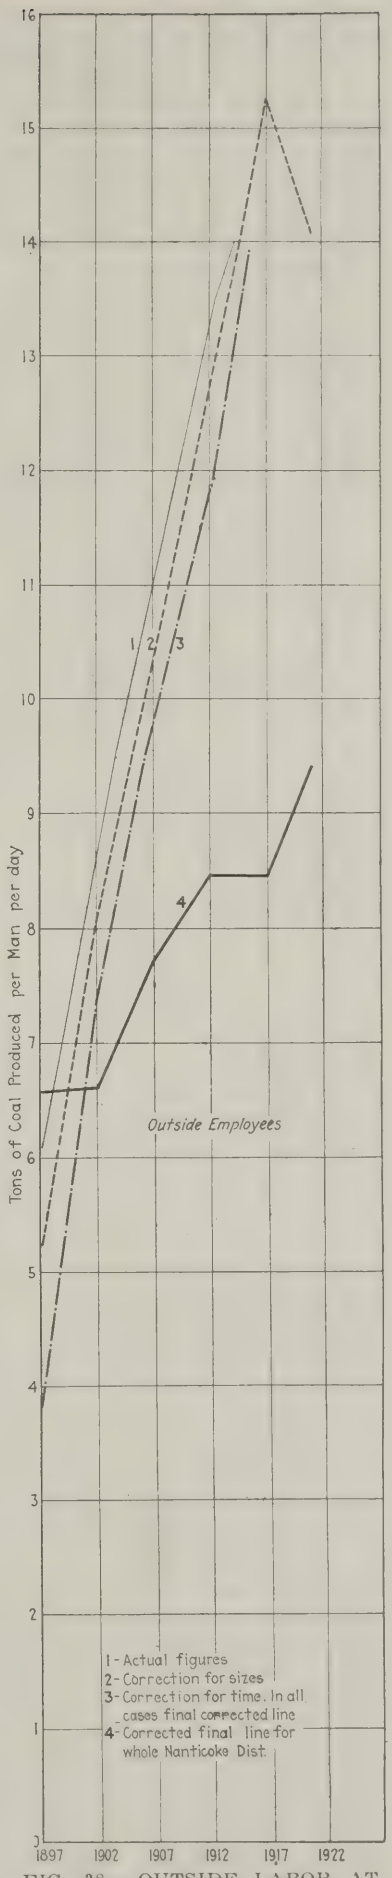

FIG. 38 — OUTSIDE LABOR AT "BIG FOUR" COMPARED WITH DISTRICT AVERAGE

Continuation of Fig. 37

TABLE XXX—PERCENTAGE OF GIVEN CLASSES OF EMPLOYEES TO TOTAL EMPLOYED

	Inside Men	Outside Men	Miners and Miners' Laborers	Inside Company Men	Miners and Miners' Laborers (a)	Inside Company Men (a)
1877	64.3	35.7	35.5	28.8	54.4	45.6
1882	66.1	33.9	44.6	21.5	67.5	32.5
1887	67.2	32.8	46.4	20.8	69.1	30.9
1892	68.0	32.0	43.0	25.0	63.1	36.9
1897	69.5	30.5	47.5	22.0	67.9	32.1
1902	70.8	29.2	43.7	26.1	61.7	38.3
1907	74.7	25.2	47.5	27.2	63.6	36.4
1912	77.8	22.2	51.8	26.0	66.8	33.2
1917	76.3	23.7	47.1	29.2	61.8	38.2
1921	78.6	21.2	50.1	28.5	63.8	36.2

(a) Percentage to inside employees.

inside. But when production began to mount the two curves crossed each other in 1912, and from then on the production from the modern collieries increased from 2.74 tons per inside employee in 1912 to 3.05 tons in 1921, or 13.8 per cent in 9 years, while the average for the district decreased from 2.74 to 2.58, or 5.8 per cent. In other words the production of the modern collieries is 18.2 per cent greater per inside man than the average of the district. The miners' and miners' laborers' curve in Fig. 37 shows practically the same thing and the same explanation applies to it.

During development numerous extra men are required on construction and other work about a colliery. This is brought out in the ascent in the curves for the production per day for inside company employees, which is the top set of curves in Fig. 37. Here while development was at its height there was a decrease in production per man, and then when conditions became normal the production increased. In this case it increased from 6.95 tons in 1907 to 8.96 tons in 1921, or 28.8 per cent.

SAFETY OF THE EXCELLIGHT—Writing to *Coal Age* George Stern takes exception to certain remarks which appeared in the issue of Jan. 4 as to the foolproofness of the Excellight, which lamp, he says, has been tested by the Board of Fire Underwriters, the report of which he quotes as follows: "This appliance is so designed and constructed that its ordinary use will not cause ignition of explosive mixtures of gases or vapors with air which may be present in the atmosphere surrounding the device. A study of the design and a consideration of the results of the dropping tests show that the bulb is well protected against accidental breakage. The explosion test showed that the operation of the switch or the removal of the top with the switch in the 'on' position will not cause a spark of sufficient intensity to ignite an explosive mixture of gasoline vapor and air."

He adds: "Although tests have never been conducted on the Excellight to determine how it would stand up in mixtures of explosives or vapor, when the bulb is shattered, we do not think it necessary to make a statement that it is not a foolproof lantern, and for these reasons: First, because the bulb is protected by a heavy wire-reinforced glass door ¼ in. thick; second, because tests have been conducted by dropping the Excellight from great heights on a concrete floor, with the result that the bulbs were never in the least damaged."

Sliding Coal Down a Hillside in a Tube

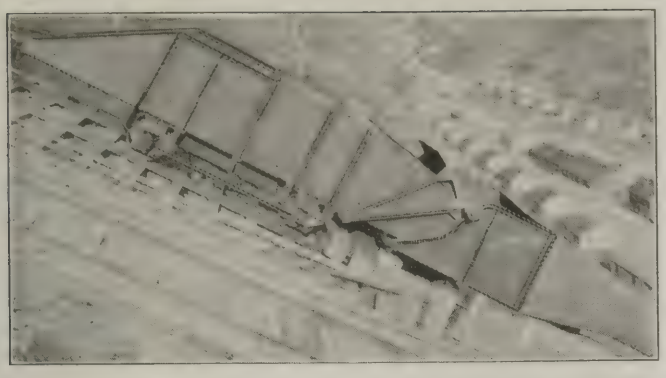
BY JOSIAH KEELY*
Kayford, W. Va.

FOR passing coal down steep sidehills the Cabin Creek Consolidated Coal Co. is using steel tubes at four operations and contemplates using several more whenever its older plants are remodeled. Some small mining companies are successfully using terra-cotta pipe in connection with a crusher for lowering coal down the mountain side, but in most cases it would be difficult to make a grade so uniform that the pipe could be placed on the ground. With terra-cotta pipe, trestles therefore would be necessary because the joints of the pipe are so short that they must have continuous support. Unfortunately, trestles are expensive and unsatisfactory. In any tube which is allowed to fill and stand for several days the coal tends to "set," and then it will not start without being jarred.

When a steel tube is used a few smart blows on its side will start the coal moving, whereas a terra-cotta tube probably would break under such a blow, and it would have to be a heavy jarring blow, for the material is such that it does not readily vibrate. In continuous operation a steel tube filled from bottom to top feeds nicely on a 33-deg. slope, but if it is left standing full for several days the coal in it has to be started. In cold weather the tube must not be left full.

The Cabin Creek company is using four steel tubes from 30 to 36 in. in diameter and from 100 to 220 ft. long, and they are placed on 33-, 36-, 37- and 40-deg. slopes respectively. A 33-deg. slope is just a little scant. An inclination of 35 or 36 deg. is about ideal where the run is as irregular as it is in the coal business.

I can see little difference in the way gas and splint coal run through a steel tube. The first installation at the Cabin Creek mines was on a 36-deg. slope, and it carried gas coal. Believing the splint coal would run more freely, we tried 33 deg. on a 220-ft. tube. The coal feeds perfectly after it has started, but, as before mentioned, it will not start from rest without assistance after lying in the tube a few days.



Even where minimum breakage is desired, I can see

LOADING TUBE FOR MONITOR ON INCLINE

Unfortunately this hill was for the most part on a grade of only 25 deg., which was too easy for the use of a tube. The top and bottom were steeper and so it was possible to provide a loading and a receiving tube, the former being 104 ft. long.

*General manager, Cabin Creek Consolidated Coal & Coke Co.

RECEIVING TUBE AT FOOT OF INCLINE

This tube is 220 ft. long and lies at the bottom of the incline illustrated above. The device of the full tube, altogether apart from the monitor, is gaining favor wherever it can be used, as it causes little breakage of the coal, certainly less than with an open chute. Furthermore the upkeep is light and a degree of storage is provided to balance operation. No coal is spilled as it is where cars are lowered down an incline; there are no wrecked cars and, of course, if the tube is continuous so that monitors are not needed, no wrecked monitors either. The only trouble is in the morning during the winter when the tube must be filled. This filling breaks the coal badly.

no reason why coal could not be handled 500 ft. through a tube laid on the proper grade, but that grade would have to be sufficient and absolutely uniform. If the incline has an average slope sufficient for the carriage of the coal it is easy to provide for laying the tubing on a uniform grade, for it is of ¼-in. steel and in sections about 20 ft. long put together with flanges. It consequently is easily rolled into position, and when bolted together will span an opening of 40 ft., though it is better practice to support it every 20 ft.

As compared with grading an incline, the expense, of course, is moderate, and in order to keep the tube on the ground one can afford to excavate much material. This grading is so much narrower than for the usual double-track incline that the yardage need not be one-third as great. The tube will cost about $11 per foot on board cars at the mine. It is desirable to install the man hoist beside the line of the tube. Where this is done sections of tube can be pulled up on wheels and rolled right into place. If concrete piers are placed every 20 ft., the flanges can be set against and above the piers, thus preventing any tendency to slip. These piers need not be more than a foot thick at the top and 2 ft. wide.

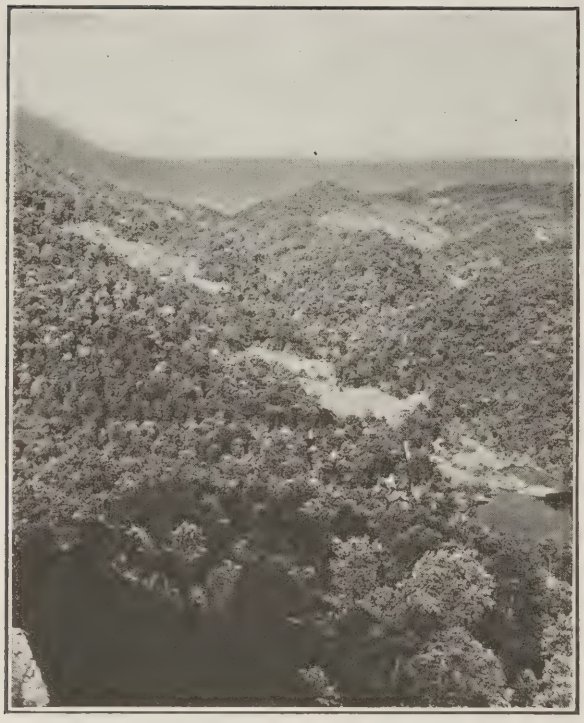
If a tube is used for the lower end of the plane, with a monitor dumping into it, it is desirable to make a telescopic joint of the first section, so that the thrust from a runaway monitor will not be communicated to the whole tube. If the tube is of considerable length it is important to have the lower end so arranged as to meet the shock of coal which is first dumped. Later dumpings, of course, cushion on the coal in the tube. There are several successful feeds for taking the coal away, but perhaps the most satisfactory is a reciprocal feed in which the hopper is never allowed to run empty, thus forming a protective cushion of coal at all times.

Of course, the steel tube eventually will wear out, but any sections showing wear in the bottom may be unbolted and given a quarter turn, thus presenting a new wearing surface. The practice of buying expensive machinery for lowering coal down short, steep grades seems theoretically unsound when gravity is there to do the work, but a common mistake is to assume that bituminous coal will act like anthracite when being fed down a slope. The problem should be carefully studied before attempting to install a gravity tube for the lowering of bituminous coal, but there is no reason why, under the right conditions, the tube should not be the simplest means of achieving that object.

One other advantage of the tube is the storage it provides, especially if it is a steam coal and breakage is no item. Almost every hillside bin designed for receiving coal from monitors will receive in practice only one-half its rated capacity, whereas with a tube and a receiving plate slightly elevated, coal may be shot up to the roof of the bin, and, without such a device the coal will pile up higher than from a monitor.

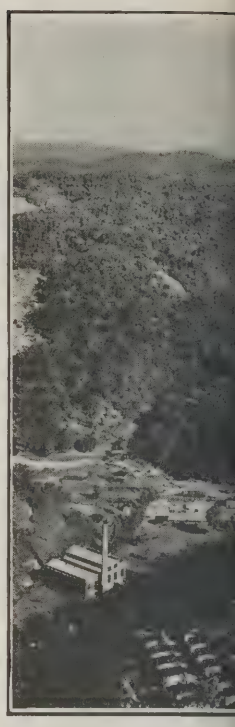
The accompanying illustrations show an operation capable of handling 6,000 tons a day, the monitor shuttling back and forth between two tubes and receiving and discharging its load automatically. In this operation both top and bottom of the hill are steep enough for tubes, but the space between is on a grade of only about 25 deg. The human element has to be taken into consideration, for if the men either at the top or at the bottom allow the tubes to get empty the breakage is excessive.

It is a splint-coal operation, however, and with little care the coal slides in a mass from the car into the upper tubes, from the tube into the monitor and from the monitor into the lower tube, entailing scarcely any breakage. When the lower tube is full, the monitor simply does not empty until the feeder draws out some of the coal; thus the tipple boss can control the situation by stopping the feed if he suspects that the men at the top are allowing the upper tube to become empty.



Of course, in a gas-coal operation the only consideration would be the wear and tear on the equipment, which would be much less if the tubes were kept full until the end of the run.

P. & R. Develops and Protects Forests



The forestry bureau of the Philadelphia & Reading Coal & Iron Co. further extended its road and trail forest protection system during 1922, so that at the end of the year it contained 130 miles of lanes or strips specially prepared to stop forest fires when the need arises. While 130 miles of such avenues of resistance to the onsweep of burning forests is insufficient to control fires in this region, each year additions will be made until eventually every 250 to 500 acres of forest land owned will be blocked off or broken up by a protective strip represented by a road, trail or fire lane. In order effectively to protect the forests, the land area has been divided into fifteen divisions or ranges and a man placed in charge of each, with responsibility for the thorough protection of the forests placed in his care. To assure results consistent with the effort made, forest owners must have the co-operation and interest of every citizen.

In furtherance of the full use of land that can be safely protected from fire the company during the year planted 70,000 Scotch pine, 5,000 Norway spruce, 14,000 Japanese larch, 1,000 hard maple, 10,000 white ash, and 10,000 white pine. Arrangements have been made to reforest 140 acres with 166,000 trees of the following kinds during 1923: Japanese red pine, European larch, red oak, white ash, Japanese larch, Norway spruce, Oriental sycamore, pitch pine, rock oak, Austrian pine and Western yellow pine. While many of these trees are not native to the anthracite region, they have been tried out in Pennsylvania, and are expected to thrive with care and public interest in their protection.

In order that trees best adapted to this region may be grown to restock protected areas, a small forest tree nursery has been developed. This year more than 90,000 seedlings will be ready for transplanting, and in a year or two sufficient for the entire needs of the company will be available.

Building a Town for a
A Glimpse of Jenkins

Largest Operation in Elkhorn Field Before Coming of the Railroads—Ground—Park and Lake Features of

By Alphonse F. Brosky*
Pittsburgh, Pa.

THE operation controlled by the Elkhorn division of the Consolidation Coal Co. consists of fourteen mines centered around Jenkins, Ky., and is larger than any similar institution in the eastern part of that state. The towns of Jenkins, McRoberts, Burdine and Dunham and the adjacent mines lie in Letcher County, which is in the southern part of the state not far from the border of Virginia.

Jenkins, the largest town, lies at the foot of Pine Mountain on the Sandy & Elkhorn Branch of the Baltimore & Ohio R.R., and on either end are the towns of Dunham and Burdine. About four miles northwest and across a mountain is the town of McRoberts, which is located on the Lexington & Eastern extension of the Louisville & Nashville R.R., the junction point being Jackson. Its importance in that section is only second to that of Jenkins.

Elkhorn District Only Recently Opened

These two railroads, which were extended into the Elkhorn district only a few years ago, opened up a vast coal-producing territory within the limits of which lies the Hazard field. Between Hazard and McRoberts many mines have been opened up recently on the branches leading from the Louisville & Nashville R.R.

Prior to 1911 what few operations had been opened in the Elkhorn district had been confined to a few mines along the Big Sandy Division and the Marrowbone Branch of the Chesapeake & Ohio R.R. The mines on the latter branch, which produce a coking coal, are in a territory adjoining the Elkhorn district, lying at the headwaters of Elkhorn Creek (a tributary of the Big Sandy River) and the headwaters of the North Fork of the Kentucky River.

The history of Kentucky as a coal-mining state, however, commences with the western field of the state and dates back to Civil War days. But so rapidly have the districts of eastern Kentucky been developed in the last ten years that in that time they have progressed further than has the western field in its half century of history. Production figures of the State of Kentucky

FIG. 1—PUBLIC PARK AT JUNCTION OF ELKHORN AND LITTLE ELKHORN CREEKS

The roadway in the foreground, which is the main street of Jenkins, is paved with concrete and has concrete sidewalks and curbs. Grass is laid out between curb and sidewalk as in the better residential portions of our larger towns and cities. The building in the rear is the company's main power station.

*Assistant editor, *Coal Age*.

Note—Headpiece shows village of Jenkins, Ky., seen from Raven Rock looking northwest in the direction of McRoberts. Elkhorn Lake, lying to the east, is an artificial lake which condenses the exhaust steam from the central power station, the energy generated in which operates the mines of the Elkhorn and Millers Creek divisions and a few mines adjoining these near McRoberts. It will be noted that the valley of Elkhorn Creek to the north of the lake curves around like a hook. Burdine lies in this hook and Dunham is located several miles to the east.

Mountain Community; and Nearby Villages

—Towns and Plants Were Erected Lumber and Brick Prepared on the Jenkins — Dwellings Painted White

for the year 1921 shows that approximately 75 per cent of the total tonnage came from the seven districts in the eastern end of that state.

Before railroads had penetrated into Letcher County the Consolidation Coal Co. procured approximately 100,000 acres of coal land in that region. In April, 1921, the Elkhorn district was opened up, its development being followed later by that of other districts. Jenkins and the other towns adjacent to it sprang up in a wilderness, yet at that time they were eighteen miles from the nearest railroad and situated in a dense forest broken only by a few clearings each with its solitary log cabin.

FIG. 2—LETCHER COUNTY, KENTUCKY AND ADJACENT COUNTRY IN THAT STATE AND VIRGINIA

McRoberts and Jenkins, the two important centers of the Elkhorn Field are separated by a mountain—that shown in the panorama above. Consequently they are approached by two entirely different railroad systems, one reaching the Ohio at Cincinnati and the other at Catlettsburg, Ky.

The Consolidation Coal Co. was the pioneer of the district. Though the lack of railroad facilities was a severe handicap, it was regarded as only one of the obstacles to be encountered in developing a mining region and, accordingly, all work went ahead on a large scale. The early history of the development of the Elkhorn holdings of this company are scarcely less instructive and perhaps more interesting than the details of the property as it is today, so engrossing are the reminiscences of the oldtimers who are still on the job.

At first all materials, supplies and machinery were hauled from Hellier, the nearest point on the Chesapeake & Ohio R.R. Many delays due to bad roads made imperative other transportation arrangements. As a result, connections were completed from Norton, Va., on the Norfolk & Western R.R., by extending a narrow-gage log tram between Glamorgan and Pound to a point half way up Pine Mountain on the Virginia side.

Here a freight terminal was established and the wagon haul shortened to four miles. To see twenty teams of oxen harnessed to a large boiler or other heavy equipment was no uncommon sight in those days. Over this route were hauled most of the materials used at the mine—food, machinery and supplies of all kinds—in fact everything from the pins and needles sold at the store to the heavy 100-hp. boilers required for the temporary power houses at the mines then being opened.

One of the first acts in construction was the erection of sawmills and later of planing mills. Practically all the lumber used in construction was cut and prepared on the property. The manufactured lumber was placed in drying kilns and made up into material for the houses which were started shortly afterward. Brick of an excellent quality was manufactured on the ground in two plants constructed for the purpose.

Just as soon as information and data were obtained by the engineering staff, drifts were opened and entries

FIG. 3—MAIN STREET, JENKINS, KY., LOOKING EAST
The ground in the right foreground is the public park. Behind it is the office building, and further beyond the recreation hall. Across the street from the latter is the general store. The greensward between curb and sidewalk adds color and beauty to the village.

driven by pick mining. At the same time work commenced on the construction of tipples, so that by due diligence in July and August, 1912, practically all the mines on the tributaries of the Baltimore & Ohio R.R. were ready to ship coal. That obtained from early development was stored on the surface until the railroads were completed. Mines on the McRoberts side were advanced to this stage about a year later, as the Louisville & Nashville R.R. was completed about at this time.

Among the problems that confront a company in the construction of an isolated mining operation are those of holding disease in check and maintaining the law. At that time "shooting scrapes" were by no means rare about Jenkins, for there were a few "bad men" to perpetrate trouble. Hazard in its day and Lynch later were faced with this difficulty.

Jenkins as it stands today is a town of real beauty, especially when viewed from Raven Rock, a bare sandstone formation to the west of the town. The villages nestled in a deep valley where the monotony of green is broken by white houses, mine buildings, roads and a condensing lake of fair size on the bank of which stands a large power house.

More Like a Suburb than a Mining Town

The main street of the town is concreted and separated from the sidewalks by plots of grass almost as wide as the street itself. These park plots are broken up at intervals by narrow walks from the sidewalks to the street, and the people of the town are prohibited from tramping down this grass, which is conditioned and kept mowed by the company.

This main street, which begins at the public park, has no residences on it. The office building (the headquarters for the Elkhorn division), the recreation hall and the department store, all of which are of brick, stand on three corners in the center of the town. To the side of the office building is a public park inclosed by a box hedge and brightened by flower beds and trees. In one corner of the park is a rustic shelter house; on the side farthest from the street stands the central station of the company and behind that lies a large artificial lake.

A large school building of brick, to which a big wing now is being added, fronts the main street. In this structure are housed a grade school and a high school, affording an elementary education as thorough as that obtainable in any large city, for the course of study includes manual training for the boys and domestic science for the girls. Night classes are conducted in mining, mechanical drawing and other subjects.

In the recreation hall is a library fully furnished and superintended by a librarian, in which are kept current magazines and a circulating library. Four denominational churches care for the spiritual needs of the people. McRoberts, Burdine and Dunham are equally well provided in these ways, though necessarily on a smaller scale.

Swinging from the main street past the power house and the park is the Lake Shore, which skirts Elkhorn Lake and leads to the residences of the company officials. A few of the homes and a large clubhouse are built overlooking the road and lake; other homes are located on a parallel street behind the road.

All the houses along the lake side are of the bungalow type and have an individuality of plan possible only where the lumber is prepared and sized on the ground. The homes of the officials have all modern conveniences, and the miners' dwellings have as many improvements as have been found practicable. These latter dwellings are of many types of construction and built for one or two families. The company favors the single-dwelling type, but limited building space compelled it to erect double houses also. The apartments of the double houses contain either four or five rooms each, while the single dwellings are provided with three or five rooms.

Big Lake Provides Ample Condensing Water

At the junction of Little Elkhorn and Elkhorn creeks, where the power plant is situated, a concrete dam 45 ft. high was erected across a narrow valley forming Elkhorn Lake, which covers an area of 18 acres with a storage capacity of 80,000,000 gallons of water. It is used primarily for the condensing of the exhaust from the power station, but has been well stocked with fish for the benefit of local rodsmen. Bathing and boating are permitted, an unusual feature in a mining town. Without a large artificial basin for the storage of water a central station cannot be operated in this mountainous country where the streams are small and swift with a tendency to dry up in the summer months.

There are 1,600 houses in Jenkins alone. These are constructed of oak, chestnut and poplar, these trees covering the mountains when the town was erected. Most of the houses are plastered, though a few are lined with beaver board. Fifty per cent of the houses are provided with sinks. The company will furnish any house with a sink if the tenant so desires.

FIG. 4—CLUB HOUSE AT JENKINS ON THE LAKE SHORE
This is fitted for the reception of about forty persons. The company laid its plans well in advance, as is shown by the fact that the grounds of this club were not disfigured by the ill-considered zeal of the lumbermen.

With the main body of the houses painted white, the color scheme of the trimmings is varied by interchanging four dark colors. Every four or five years the houses are repainted. In few places can houses profitably be painted white, for it can be done with any hope of continuance only where the air is clear of smoke and injurious gases. White paint should be used only in places far removed from the industries which produce much smoke.

Most of the lots in which houses are built are fenced in, for it has been found that the occupant feels a sense of responsibility only when his property is thus defined and protected. At many mining towns phases of community betterment are short-lived. This is not the case in isolated villages such as Jenkins, where vegetable and flower gardens have been planted each year with no apparent waning of interest. Prizes are offered for the best vegetable gardens, the prettiest flower gardens and the most attractive places.

A certificate of award accompanies the bestowal of each prize. The official photographer of the company photographs the prize-taking subject, and these are included in the official albums of the company. The company plows all lots and furnishes manure; it also supplies trees, vines and shrubbery to those who ask for them, at a cost just great enough to check wanton requests for this favor.

FIG. 5—MINERS' DWELLINGS AT NO. 202 MINE, DUNHAM

Far from the smoke of industrial furnaces and making little smoke itself, the Consolidation Coal Co. has been able to paint its houses and fences white, thus giving its villages an air of cleanliness and light.

The greater part of the water supply at Jenkins is obtained from a spring in a limestone formation on the west side of Pine Mountain. The water, which, of course, is of temporary hardness, is stored in a concrete reservoir of 1,000,000 gallons capacity. It is conducted in a 6-in. main to houses and hydrants at intervals for protection against fire. The main supply is augmented by water from deep wells, which contains much iron, making it unpleasant for household use. To remove the temporary hardness from the spring water and the iron from well water, milk of lime is used, which makes the water clear and of excellent quality. Coming from springs and wells it always is cool and potable. All towns in the division are furnished with filtered water which either is piped to the house or to hydrants conveniently located.

Due to its excellent water supply and its attention to details of sanitation, the division has never had an epidemic; occasionally several cases of disease may make their appearance, but they always prove to have been brought in from the outside. Jenkins proper is equipped with a complete sewerage system which empties into Elkhorn Creek below the town and is flushed at regular intervals by means of an automatic flushing apparatus. Garbage and rubbish are collected weekly, hauled to an isolated hollow and burned. The management does not depend upon its people to provide containers for garbage; each house is furnished with a garbage can, and each town has its garbage wagon.

FIG. 6—SCHOOL HOUSE AT McROBERTS, KY.

Elementary and high schools are both provided even in the smaller mining villages of the Consolidation Coal Co.

St. Bernard Mining Co. Has Tipple Making Thirteen Sizes and Size Groupings

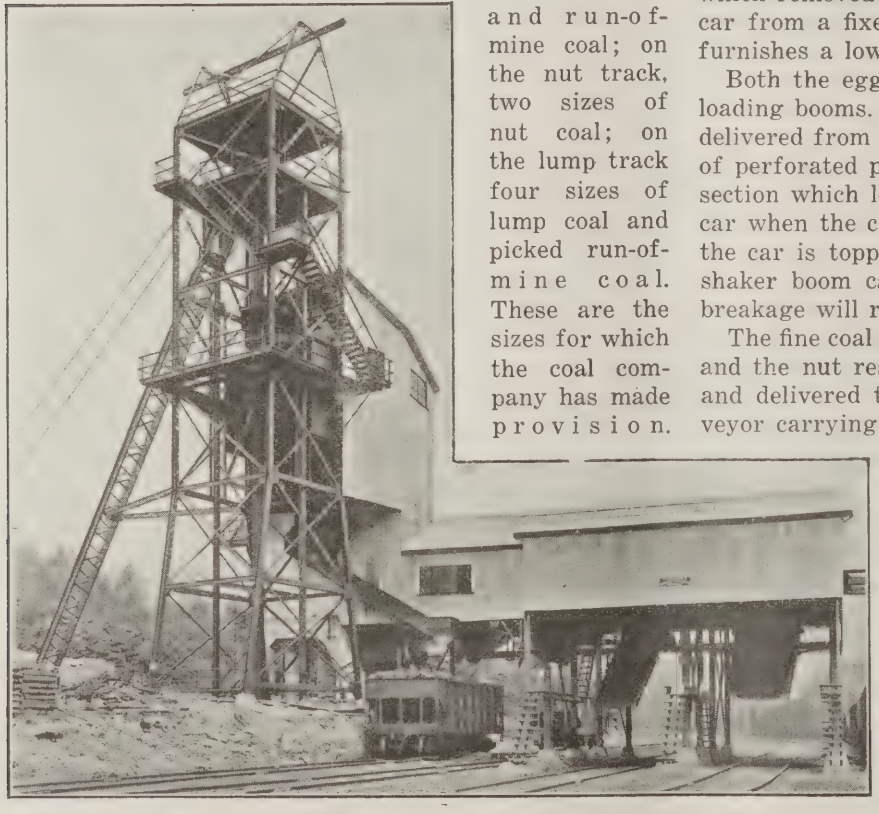
By R. G. Lawry
Chicago, Ill.

MOST recent among the operations of the St. Bernard Mining Co. is that known as the North Diamond Mine. This plant opens up a new coal territory and is the first complete mining installation made by this company for several years.

Extensive drilling and an unusually careful study of the general mining problem preceded the location of the shaft and the development of the new property. The size of the shaft was made to conform to the size of the mine car which the St. Bernard Mining Co. is adopting for all its mines, the expectation being that when finally the old cars in use at the nine mines of the company go to the scrap heap, they will all be replaced by cars of the new standard.

In deciding the design of the screens and the tipple, the sales department of the company made a careful study as to the sizes of coal the market would be likely to demand, and after considering the experience of the past and anticipating the needs of the future drew up a schedule of the sizes for the approval of the higher officials of the coal company. Only when this had been done were the engineers allowed to proceed with the design of the tipple.

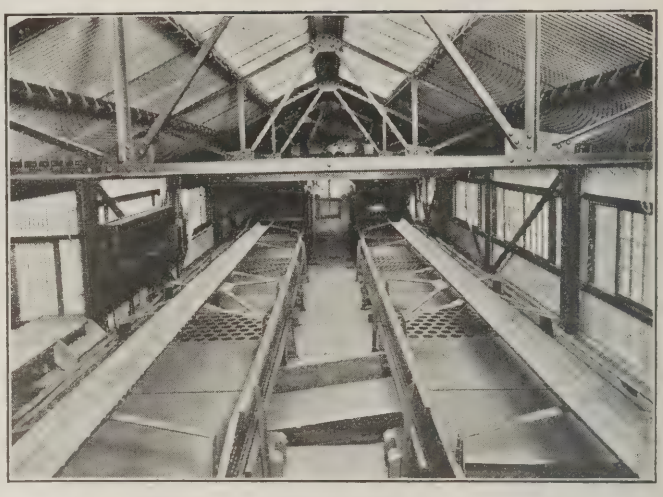
This building at the North Diamond Mine has a steel frame covered with galvanized corrugated iron. The tower of the tipple is of the end-pull type, but is turned about 74 deg. from the usual position occupied by this kind of tower, the screening machinery being placed to one side. Although this design is unusual, it is a convenient arrangement for the style of equipment used.



The cars are hoisted in Olson cages and dumped at the top into a weigh hopper which serves both cageways. This weigh hopper has a double-bottom dump with gravity doors and is hung on 15-ton suspension scales with a quick weighing dial. The weigh hopper

dumps into the feeder hopper in such a way that the forward dump serves the feeder hopper of one screen and the backward dump serves the feeder hopper of the other screen. It is only necessary for the weighman to alternate the dumps. This is no trouble, for should he, by mistake, dump too often to one side, no harm would be done. By opening the door in the inside part of the feeder hopper the backward dump of the weigh hopper delivers unpicked run-of-mine to a chute which carries it along to the screenings track without the operation of any machinery.

Each feeder hopper is equipped with a reciprocating feeder driven by two ball-faced, babbitted eccentrics which have an adjustable stroke by means of which the feed to each screen can be regulated. Each feeder is driven by means of a belt from a line shaft and can be thrown in or out of gear by means of a friction clutch. The screens also, which are of Marcus type, are driven each by the line shaft of its own feeder, this line shaft in each case being actuated by a 30-hp. slip-ring motor. The drive of the screen is controlled by a friction clutch.



Each of the two screens is 5 ft. wide and designed to handle run-of-mine coal at the rate of 200 tons per hour. Over each screen is a trough on which pickers place the refuse. This trough extends over the run-around track at the end of the tipple and delivers the refuse to a wood bin from which it is loaded into wagons and used for filling around the property.

Each screen has circular perforations of four sizes, the diameters of which are 1⅛ in., 2 in., 3 in. and 5 in. Thus five sizes are made when lump coal is considered. Provision having been made for the mixing of various combinations of the different sizes, thirteen distinct size combinations and sizes of coal can be delivered. For instance, on the screening track can be loaded two sizes of screenings and run-of-mine coal; on the nut track, two sizes of nut coal; on the lump track four sizes of lump coal and picked run-of-mine coal. These are the sizes for which the coal company has made provision. However, other sizes can be made without changing the size of the screen plates. By changing the sizes of the perforations, of course, any size or combination of screened coal can be made.

SIDE ELEVATION NORTH DIAMOND MINE, ST. BERNARD MINING CO.

The unpicked run-of-mine chute passes to the outside of the building and can be seen on the left. The hoist house instead of being alongside the railroad track is up the hill a trifle and thus removed about 74 deg. from the usual position. The sized coal is loaded by shaker loading booms which have rescreens through which the fine coal passes. This is collected in a screw conveyor and delivered to the screenings track.

SCREEN ROOM OF NORTH DIAMOND TIPPLE

Each screen and its feeder is operated by a 30-hp. slip-ring motor. The coal in passing from the rear ground to the foreground passes over perforations of 1⅛-in., 2-in., 3-in. and 5-in. diameter, leaving the smaller sizes at each screen. The refuse is picked off and placed in the trough and travels toward the foreground like the coal.

The screenings are delivered to the car by means of a hopper which collects the coal from both screens and delivers it at one point. At the bottom of this hopper is a swinging undercut gate which will stop the flow of coal while a loaded car is run out and an empty placed in position for loading.

The nut coal is collected from two gates on each screen and delivered to a shaking chute. All this nut coal then passes over a rescreen section in the chute which removed the fine coal. It is then loaded into the car from a fixed chute with a hinged extension which furnishes a lower loading point for small cars.

Both the egg and lump coals are loaded over shaker loading booms. These booms collect the coal after it is delivered from the screen and rescreen it over a section of perforated plate. The shaker booms have a pivoted section which lowers to a point near the bottom of the car when the car is empty and gradually runs up until the car is topped out. If the operative uses care, the shaker boom can be kept close to the load so that no breakage will result from the dropping of the coal.

The fine coal rescreened from the lump and egg booms, and the nut rescreen are collected in a screw conveyor and delivered to the screening chute. The screw conveyor carrying the degradation is driven by a separate direct-connected motor. Each loading boom and the nut shaker chute has its own motor. All light and power wires are carried in iron conduit, adherence being given throughout to the requirements of the National Underwriters Code. The controls for all the motors in the tipple are placed on the side of the screen house at a point about over the nut track. This is a central point convenient to the pickers and also is handy for anyone coming up from the track by a stairway located on the side of the boom house. This tipple installation was designed and built complete by the Roberts & Schaefer Co., of Chicago.

Mine Laws Lax on Handling and Storing of Explosives

MUCH interest has been centered this winter around the explosions in coal mines, some of which occurred at collieries where what are regarded as the best methods of assuring safety were stringently followed. Owing to these explosions new legislation is to be expected. All the dangers are not below ground nor are all of them due to the faults of individual employees. In some cases the management itself is largely, if not wholly, to blame, and perhaps in no particular is this more evident than in the handling of explosives, accidents from which, fortunately, have been fewer than could have been expected in view of the many risks run.

Unless the mining laws of the states are made to specify what may and what may not be done in the handling of explosives we shall awaken one day to find a disaster on our hands. Then there will be a scurrying in the right direction. Ought we not to correct the evil now rather than wait till the lesson is taught us by the grim example of the loss of many lives?

To the operator in the Pittsburgh district a significant lesson was taught only recently, fortunately without any lives being lost to drive that lesson home. It will be well indeed if the bloodless but expensive accident by which the lesson was given will be successful in rooting out the many bad practices that prevail.

On the night of March 26 at the Superior mine of the Superior Fuel Co., near Pittsburgh, a magazine exploded containing about 225 lb. of permissible powder. Though the damage was slight, the thought of what might have been and the facts in the case are indeed alarming. With the demolition of the magazine, evidence of the cause was destroyed. Because the explosive was stored on a rack directly above a steam pipe carrying exhaust steam it is thought by some that local overheating of the dynamite may have been the agent by which the disastrous powder explosion was caused.

Others have suggested that the paraffin in the cartridge may have melted and dripped on the steam pipe, carrying with it small quantities of the highly inflammable ingredients of the explosive. These, it is suggested, burst into flame, then lighted an accumulation of similar material on the floor.

The force of the blast was severe enough to rock the countryside within a radius of three-quarters of a mile of the plant. Windows were shattered, and the populace of the town adjoining the mine was exposed to the danger of flying missiles.

Investigation has disclosed that the location and the general practices in the maintenance of the magazine were both needlessly hazardous. The magazine site lay not more than 50 ft. from the air-and-material shaft, where a fan electrically operated and a steam-driven standby unit were housed. This last unit, which lay the nearer of the two to the magazine, was wrecked; the auxiliary hoist room was demolished and the walls of the boiler room were partly ripped out on the sides nearest the magazine.

If this explosion had taken place about 7 a.m., when the miners were gathered around this shaft waiting to descend, few would have escaped death. If a few additional pounds of explosive had been stored here and the blast had occurred while the men were underground, both fans would have been destroyed, cutting off air to the workings. Then, also the power plant nearby might have been incapacitated, in which case the main hoisting equipment would have been crippled for want of power, and the miners would have been trapped.

Summarizing the facts in this case we learn that: (1) The magazine was located too near to the airshaft in particular and the mine plant in general; (2) the

NOTE—Headpiece shows the mine of the Superior Fuel Co. after the powder-house explosion which wrecked the fan and other surface equipment at that mine.

construction of the magazine was not according to specifications recommended by the U. S. Bureau of Mines or the makers of explosives; (3) care was said not to have been exercised to keep the interior of the magazine clean. It also is said that ingredients spilling from the explosive were allowed to accumulate on the floor over a period of years. Such material is highly inflammable, especially at the temperature which is believed to have existed. (4) Detonators were stored in the same compartment as the dynamite.

Where mining laws do not regulate certain features in operation the state mine departments are empowered to order that any dangerous condition be remedied. Any one of these listed will make storage of explosives unsafe, and one or more of these is known to prevail at many mines. Even in the states where there are no blanket regulations in regard to explosives why have the state mine departments allowed such practices? It is time that all states enacted specific and detailed laws covering the location, construction and maintenance of magazines, as also the distribution and use of the explosives they contain.

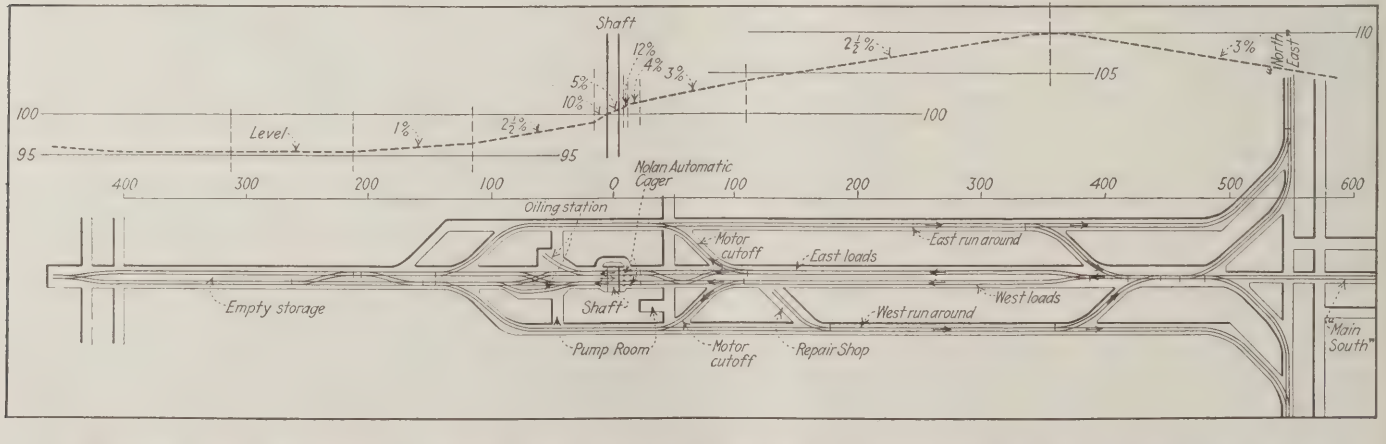
The industry should go on record as recommending that these laws specify: (1) That explosive magazines be located in agreement with the American Table of Distances; (2) that the construction of magazines as regards design, material, heating, ventilation and barricading be in accord with recognized safe practice; (3) that the storage of detonators and dynamite in the same compartment be considered a penal offense; (4) that the attendant in the magazine perform his duties in accordance with rules prepared for his instruction; (5) that the distribution and uses of explosives be better regulated.

Made Over 2,100 Hoists in Eight Hours

By Charles F. Sherman*
Peoria, Ill.

MANAGEMENT in hoisting is best shown not by the number of tons hoisted but by the number of hoists. In consequence the record made on Feb. 28 of this year at the Groveland Coal Mining Co.'s No. 2 mine, Peoria, Tazewell County, Ill., of 2,115 hoists in eight hours, or 264⅜ hoists per hour, is worthy of more than usual note even though the cars were of only 1½ tons capacity. The hoists were as follows:

	Hoists		Hoists
First hour	263	Carried forward	1,071
Second hour	263	Fifth hour	271
Third hour	243	Sixth hour	260
Fourth hour	302	Seventh hour	254
		Eighth hour	259
Total	1,071	Grand total	2,115



So far as I have been able to ascertain, this record exceeds all others hitherto made. The record, I believe, formerly was held by the Vermilion mine of the United States Fuel Co., near Danville, Ill., with 2,026 hoists.† The average hoisting period at the Groveland mine was 13.617 seconds, and at the Vermilion mine 14.215 seconds. It will be noted that during the fourth hour 302 hoists were made, or a fraction over five hoists per minute. This rate continued for 65 minutes. Every move on that day was timed with a stop watch and it was noted that in that 65-minute period 325 cars were hoisted. When it is known that the total hoist is 202 ft., that the cages weigh 3 tons, the cars 1 ton, and the coal approximately 1½ tons it will be realized that this is a remarkable record.

The Groveland mine is located at Peoria, Ill. Don Wills is mine manager and George Long and Grover Hooten are the hoisting engineers who made the record, alternating at the throttle every 30 min. during the eight hours. The mine is in No. 5 seam, which at this plant is 4 ft. 2 in. thick. It is operated on the advancing room-and-pillar system. The panel entries are driven 1,800 ft. apart, East and West Room Entries being driven north and south respectively. These room entries are driven at such a distance apart that a 420-ft. block of coal is left between them. The rooms are driven 200 ft. long, leaving a 20-ft. pillar at their ends. On each side of all main and panel entries a 75-ft. barrier pillar has been provided. The rooms are driven on 30-ft. centers, 24 ft. wide, leaving 6-ft. pillars.

The seam at this point is underlaid by about 12 in. to 18 in. of fireclay, and below this is 18 in. to 24 in. of iron band. Over the coal is an irregular black slate ranging in thickness from 24 in. to nothing. Above the slate is an unstratified clod which runs from nothing to 15 ft. thick. Above this clod is a sandrock 12 to 15 ft. thick and running in enormous rolls, sometimes lifting its lower surface 15 or 20 ft. above the coal and then immediately thereafter dropping to the very top of the seam.

This sandrock is completely saturated with water,

*General superintendent, Groveland Coal Mining Co., Peoria, Ill.
†4,858 tons.

GROVELAND COAL MINING CO.'S CAGING AND DECAGING GRADES BY WHICH RECORD DAY'S HOIST WAS MADE

The grade on the cage is shown as 5 per cent. This, however, is reduced to 2½ per cent, as the text shows. Note the 12 per cent for 30 in. on the caging side and 10 per cent for a longer distance on the empty side. These grades were made as the result of experiment on the spot and were not merely good guesses of the engineering department. They are made to fit the caging conditions and the cars to be caged. Are your grades the best that can be devised for speedy caging?

causing the mine to be very wet. Water drips constantly from the roof, and twelve pumps have to be operated 24 hours per day.

The cars are gathered from the face by 50-in. mules and Welsh ponies which haul to inside gathering partings, from which they are transferred to the shaft bottom by electric haulage locomotives. The cars are caged with the aid of Nolan automatic cagers, and the cages are hoisted by a pair of direct-connected Crawford-McCrimmon 20 x 36-in. engines with a 6-ft. straight cylindrical drum. A Litchfield throttle is used to control the admission of steam to the cylinders. The engines are also provided with a Welch automatic overwind and overspeed device. The cages are equipped with automatically operating stop horns and rebound blocks of Mining Safety Device Co. type.

The actual caging time is exactly 2 seconds, the other 10 seconds being occupied by the movement of the cage. This extremely rapid caging time is made possible by a unique arrangement of grades on the track at the shaft bottom. These different grades were worked out and adopted only after many weeks of careful investigation made by changing the grades night after night and watching the performance of cars on them through the daytime, before the automatic cagers were installed.

Then the automatic cagers were ordered made to specifications as to grades which we found would cage our cars in the shortest time possible. We first changed the grade on our cages from horizontal to 2½ per cent in favor of the loads. Then we adopted 42 in. of 5 per cent grade immediately approaching the cages. Behind this is 30 in. of 12 per cent grade on which the loaded car stands. Back of this is a 4 per cent grade past the crossover switches, and a 2½ per cent grade back of this. The empties drop off the cage onto a 10-per cent gradient, and then run away on a grade of 2½ per cent. As the hoisting tonnage depends entirely upon the rapidity with which the cars are caged and hoisted, months of thought and study were devoted to this question alone, and the record mentioned in this article is the result.

Mechanical Loader Excavates a Side Track

AT MINE No. 206 of the Consolidation Coal Co., Jenkins, Ky., a side track for empties had to be excavated in a bed of solid clay, the depth of the cut averaging 6 ft. Accordingly a crew of eleven men with picks and shovels were set to work to dig, load, tram and dump the material, but it was discovered that the picks made little impression on the clay and that dynamite was needed to dislodge it effectually. Even then, using fifty-four sticks of dynamite in a day of eight hours the eleven men could do no better than load out twenty-two 2-ton mine cars. Yet these men had no other duties than that of loading, tramming and dumping the spoil.

An old-type Halby shovel happened to be available and this was brought to the excavation. With its aid a crew of five men, comprising two men on the locomotive, which was kept in constant attendance, two tracklayers and one machine runner, could load forty mine cars of the clay in eight hours at a great saving in cost. With this shovel it was not necessary to use dynamite or powder to loosen up the clay.

This unusual application of the loading machine is significant, for it suggests that the coal loader has other useful applications than the loading of coal or rock at the working face. In the laying of outside track at a drift mine, in the construction of railroad tracks, in the preparation of sites for buildings, in the digging of new stream channels, in the making of village roads more or less grading has to be done which, in the past, for want of a better method has been accomplished by pick and shovel. The saving that may be effected by using a mechanical loader may go a long way during the construction period to defray the first cost of the machine itself.

EXCAVATING CLAY WITH LOADING MACHINE

Long before a mine is opened a loading machine has its uses in excavating on the surface. Sometimes, but rarely, a steam shovel is available at a mine to make the deeper cuts, but where it is not, a mechanical loader of the right type will do the work.
